EXPOSÉ OF OPIUM ANTIDOTES.—Dr. J. B. Mattison, of Brooklyn, has published some interesting facts, showing the real ingredients of these nostrums. An "opium antidote" of S. B. Collins, of La Porte, Ind., contains, according to an analysis done under the direction of Dr. E. A. Squibb, sulphate of morphia in the proportion of 4.45 per cent., with a little glycerine and water. Another "antidote," prepared by Mrs. J. A. Drollinger, formerly Mrs. S. B. Collins, contains 3.2 per cent. of the sulphate of morphia, according to the analysis of Prof. Carmichael, of Bowdoin College. Another sample contained 1.383 per cent. Prof. Chaillé, of New Orleans, procured an article

sold by J. C. Beck, of Cincinnati, who claimed it had no opium in it. Mr. J. Johnson, chemist of the New Orleans Charity Hospital, reported that it held ten grains of opium to the ounce. Drollinger claims that her antidote "does not contain opium in any of its numerous forms."

DR. GURDON BUCK.—At a meeting of the New York Medical and Surgical Society, held April 14, 1877, the following resolutions were adopted:

*Resolved*, That the members of this Society have heard with sincere regret the tidings of the death of their distinguished associate, Gurdon Buck, M.D.

*Resolved*, That we entertain a grateful recollection of the qualities of mind and heart by which he distinguished himself as an able and skilful surgeon, a sincere friend, an upright citizen, and an earnest Christian.

*Resolved*, That we tender to the family of the deceased our sincere sympathy with them in their painful bereavement.

*Resolved*, That a copy of these resolutions be sent to the Medical Journals, and to the family of the deceased.

JAMES R. WOOD, *President*.

J. W. McLANE, *Secretary*.

MORTALITY OF SURGICAL OPERATIONS IN THE UPPER LAKE STATES.—A pamphlet "On the Mortality of Surgical Operations in the Upper Lake States, compared with that of other Regions," by Edmund Andrews, A.M., M.D., gives a complete résumé of the opinions of the greatest surgeons on the value of operations and the causes requiring them. To the discussion of each opinion are appended remarks showing the contradictions of the chief surgical authorities. The materials for this essay have been gathered from the surgical literature of both continents with great care, and the search for statistics among French, German, and other authorities has evidently been attended with immense labor. The result of some operations in the Lake States differ remarkably from those in other regions. Thus herniotomy shows a mortality of 24 per cent. in the Lake State while abroad the mortality is 49 per cent. Resection of shoulder, abroad 32 per cent., in Lake States 0 per cent. Ovariotomy, in Lake States 28 per cent., abroad 29 per cent., while, on the contrary, lithotomy and other operations are more dangerous in the Lake State the mortality in laryngotomy and tracheotomy abroad averaging only 54 per cent., while in the Lake State it is 81 per cent.

This is the most thorough condensation of the subject in our language, and will be of great use to surgeons desiring to know the risk of each operation on the opinion of the authorities concerning it. The pamphlet is a reprint of Dr. Andrews's recent series of articles in the *Chicago Medical Journal*.

MEDICINE AND INFIDELITY.—In his valedictory address to the graduates of the University of Louisville, Dr. Richard O. Cowling discusses the relation of medicine to modern unbelief in a very able manner and disproves the assertion that wherever three doctors are gathered together there will be found two infidels. Paget, John Hunter, Gross, Rogers, and others are cited as examples of devout Christians, whose professional calling and scientific attainments did not cause them to become infidels.

THE TRAINING-SCHOOL FOR NURSES to be opened at the New York Hospital includes, in its course of three years, practical and theoretical instruction in medical, surgical, and special nursing, bandaging, the elements

of anatomy, physiology, hygiene, etc. One month in each year will be passed in the kitchen, and one in the laundry, experienced instructors directing each department. A second class will be formed at the end of the first year, and the first class will become head nurses of the wards for the second year. Each candidate must pass a satisfactory examination before receiving her diploma; must be between the ages of 20 and 30, strong, in good health, and of fair English education. The limit is twelve students to each class, and a certificate of good character from a satisfactory source is indispensable.

All the provisions are excellent with the exception of that relating to the ages of applicants, which might be extended to forty or even forty-five years without prejudice to the institution. There is one instance where the youth of the nurses in a training-school was a positive disadvantage to the patients, a source of vexation to the matron, and a paradise of flirtation to the young ladies in training.

**HEALTH OF GEORGIA.**—The Second Annual Report of the State Board of Health of Georgia is replete with practical suggestions, the most important of which is the refutation given by the figures of the different tables to the theory of the local origin of yellow fever.

The loss caused by this dreaded scourge is estimated at \$5,862,357.00; but to the families rendered desolate this amount is a mere trifle, death having removed what was priceless.

**WILLARD ASYLUM FOR INSANE, N. Y.**—The Eighth Annual Report of the Trustees of the Willard Asylum for the Insane shows a freedom from debt and a general prosperity which is refreshing. The whole number treated was 1,280, and the daily average during the year was 1,076. Various improvements already made and in progress show the energy and zeal of the directors of the institution. The Asylum was instituted by the Act of 1865, creating it for the better care of the insane poor, and it has fully met its purpose, being to-day a noble monument of charity, and an honor to the State.

**DR. SEGUIN'S PRESCRIPTION AND CLINIC RECORD** is a valuable aid to the busy practitioner, its object being to give more precision and certainty to prescriptions by writing them twice—once for keeping, the other for the apothecary—to record the signs of disease on the spot, etc., to enable a physician to continue the treatment of an absent confrère, etc., etc. In the treatment of grave disorders, fevers, pulmonary and other diseases, this record will prove invaluable.

**PROF. D. B. ST. JOHN ROOSA**, of this city, has been elected Corresponding Member of the Medico-Chirurgical Society of Edinburgh, Scotland.

**MARYLAND MEDICAL JOURNAL, BALTIMORE.**—The first number of this journal has made its appearance under the editorship of Dr. H. E. T. Manning and T. A. Ashby, who are also the publishers and proprietors. It is of octavo size, thirty-six pages, and presents an exceedingly creditable appearance. The editorial announcement, after rehearsing the triumphs of medical journalism, says: "And yet, with all this array, there's room, we believe, nay more, there is need for further enterprise in this department of literature." We hope that the profession in and around Baltimore will be ready to give a practical endorsement of this sentiment.

**THE REPORT OF THE FIRST CONGRESS OF THE INTERNATIONAL OTOLOGICAL SOCIETY**, held in New York, Sept., 1876 (D. Appleton & Co., N. Y.), contains the

following: Report on the Progress of Otolology, by Drs. C. H. Burnett and C. J. Blake; Aspergillus Glaucaus in the Tympanum, with a case, by Dr. C. H. Burnett; Primary Acute Periostitis of both Mastoid Processes, by Dr. H. Knapp; Case of Exostosis of the Ext. Auditory Meatus drilled out by the "Dental Engine," by Dr. Arthur Matthewson; Test Sentences for determining the Hearing Power, also two cases of Acute Inflammation of Schrapnell's Membrane, by Dr. A. H. Buek; Sketch of Early Development of Ear and Eye in the Pig, etc., by Dr. David Hunt; Perforation of Membrana Tympani with scarcely a Symptom of Disease, by Dr. E. L. Holmes; Gaseous Interchange in the Tympanic Cavity, etc., by Dr. A. Loewenberg; Application of Paper Dressings in the Treatment of Perforations of the Membrana Tympani, by Dr. C. J. Blake; Case of Abscess over the Mastoid Region, etc., involving Brain without harm to Auditory Apparatus, by Dr. O. D. Pomeroy; Syphilis of the Cochlea, (Coehlitis), by Dr. D. B. St. John Roosa; and Hyperostosis of the Mastoid, by Dr. J. Orne Green.

**SACRIFICED TO PROFESSIONAL DUTY.**—Dr. N. Gerhard Hutchison died April 10th, in his 24th year, a victim to diphtheria contracted in the pursuit of his calling. He had been attending several cases of that disease, and about one week before his death performed tracheotomy for the relief of one of them. Soon after he was himself attacked, the disease running a rapid and most painful course. He was the third in a direct line of physicians, the only son of Dr. J. C. Hutchison. His untimely demise falls with grievous weight upon his parents and family. He was a graduate of the College of Physicians and Surgeons in 1875, held the assistant-surgeoncy of the Twenty-third Regiment, and had been connected with St. Peter's Hospital and Orthopaedic Infirmary. —*Proceedings Med. Soc., Co. Kings, Brooklyn, N. Y.*

**AMERICAN MEDICAL ASSOCIATION.**—The twenty-eighth annual session of this Association will be held in the city of Chicago, Ill., Tuesday, June 5, 1877. Secretaries of medical societies are requested to send list of delegates as early as possible to Dr. A. B. Atkinson, Permanent Secretary, 1400 Pine Street, Philadelphia, Pa.

**DISTRICT MEDICAL SOCIETY, COUNTY OF HUDSON, N. J.**—At the Annual Meeting of the District Medical Society for the County of Hudson, N. J., held in Jersey City on May 1st, the following were elected for the ensuing year:

President, Dr. Henry Mitchell; Vice-President, Dr. W. R. Fisher; Secretary, Dr. L. J. Gordon; Treasurer, Dr. F. Geisler; Reporter, Dr. M. Sampson.

Delegates to the Medical Society of New Jersey: Drs. S. R. Forman, J. W. Hunt, T. F. Morris, J. J. Prendergast, J. R. Waldmeyer, L. J. Gordon, W. R. Fisher.

Delegates to the American Medical Association: Drs. A. A. Lutkins, J. H. Vondy, J. W. Hunt, F. C. Selnow.

**AMBROSE PARÉ AND THE LIGATURE.**—Mr. H. Wood, Jr., printseller, 826 Broadway, has published an excellent, large-sized photograph of the celebrated engraving of Ambrose Paré at work upon the battle-field. The surgeon forms the central figure of a group of twenty or more standing by a patient, after having performed amputation at the lower extremity. With one hand he grasps the femoral with the forceps, and in the other some ligatures, declining the cautery irons which are proffered and ready for use. The patient vividly represents the old-timed horrors of amputation. Half-supported and half-controlled by

assistants, the expression and *pose* are studies. In the foreground the rude hand-furnace is heating the irons, and a surgeon applying one of the latter to a perforated wound of the right chest. The other figures are admirably placed, and the make-up of the picture is artistic and imposing.

**THE LECTURE ON ANATOMY.**—The same publisher has also issued an admirably executed photographic copy of Rembrandt's Lecture on Anatomy, the engraving of which is now, like the preceding, very rare. The lecturer is represented demonstrating the flexors of the hand to a class of earnest students surrounding a subject.

**ASSOCIATION OF AMERICAN MEDICAL COLLEGES.**—A meeting of the Provisional Association of American Medical Colleges will be held at the Palmer House, Chicago, on Saturday, June 2, 1877, at ten o'clock A. M. All colleges represented at the meeting of the Association held June, 1876, are invited to send delegates to the ensuing meeting, and all chartered medical colleges in the United States recognized as "regular" by the colleges already represented in this Association are also invited to send delegates from their Faculties to the said meeting.

J. B. BIDDLE, M.D., President.

**HYDROPHOBIA.**—Deaths from hydrophobia, which have occurred recently in the Prussian-Rhenish province, have called the attention of the Government to the practice, much prevailing there, of having persons who show symptoms of hydrophobia treated, instead of by a medical man, by a Roman Catholic priest. The consequences have naturally enough and invariably been disastrous to the patients. Another superstition existing in the Rhenish province is the belief that the bite of dogs which have been burned with the Hubertus key can never be dangerous, and this belief is producing a large revenue to a Belgian convent, which sends out emissaries with Hubertus keys to perform this interesting operation. The Prussian Government has now, in order to prevent further misfortunes, reminded the Roman Catholic clergy of a Government decree, according to which the clerical treatment of persons showing symptoms of hydrophobia can be commenced only when it has been proved to the priestly operator that the person bitten is already under medical treatment.

**OBSTINATE CONSTIPATION.**—The following letter, addressed to a practitioner in this city by a patient, is self-explanatory. It is to be hoped that some of our readers may be able to suggest a convenient and efficacious remedy:

"During my short but eventful career I have punished my share of all kinds and descriptions of ardent *spirits*. For the past seven months I have not drunk a drop. During all that time, and for the first time in my life, my bowels have been in a state of chronic constipation, and I have no doubt my liver is like a piece of cork. One of your most powerful liver-stirring doses, which would probably nearly physic a horse to death, appears to agree with me, like a suitable meal of victuals, and causes only one gentle movement, apparently natural. After that, if I took no more cathartic of some kind, I should probably go a year or two without further movement.

"Of course, this is a very convenient state of things, but I am afraid I should eventually fill up, so that my victuals would not taste well, and besides I might die in the summer-time and am afraid I shouldn't keep well. I thought, perhaps, you might prescribe a sort of pill diet, and allow me to break my strict temperance rules by taking one or two castor-oil cocktails before breakfast, with an aloe punch in the middle of the day.

I went one whole week, eating nothing but oatmeal, corn-meal gruel, baked and raw apples, etc., etc. It made no difference, and it convinces me that there is something wrong about the organization of my *innards*.

"If you think my liver is unfit to preside over its department, could you appoint some one of my other vitals '*Liver ad interim*'? Anything you say, I am not one of the kind who always imagine themselves sick; I am well enough any way, but either want some benefit from my numerous bowels, or else I don't want the trouble of carrying them about.

"I shall expect you to charge one visit to pay you for reading this amateur diagnosis, and then if you agree with me that my bowels are of no further use to me, render me a bill, I will pay up, and at once commit harikari."

**FOTHERGILL'S HANDBOOK OF TREATMENT.**—Dr. A. H. S., of this city, writes: "Permit me to call attention to two typographical errors in Fothergill's *Handbook of Treatment*, which might pass unnoticed and lead to disastrous results. On page 45 is given a formula containing hydrocyanic acid, in which the bulk is directed to be increased by the addition of water to eight *drachms* instead of eight *ounces*, as was doubtless intended. As the prescription now stands the patient would take at once twelve to sixteen minims of the dilute acid, which might render a repetition of the dose unnecessary. On the very next page a small *l* is substituted for a small *i* in prescribing extract of nuxvomica, thus multiplying the dose by 50. As this is required to be made into a pill, this error is less dangerous than the other; still, there is no telling what a young machine-made doctor and a country grocer-druggist might not do with such a prescription."

**PROPAGATION OF TYPHOID BY MILK.**—The medical officer of health for St. Pancras, Dr. Stevenson, reports a circumscribed outbreak of typhoid fever in his district, which was determined by the distribution of the typhoid fever poison in a particular milk-supply. Forty six cases of the disease occurred within a brief period, and of these cases forty-one consumed milk obtained from one and the same source. Of the five other cases, two were imported into the locality, two were developed under conditions ordinarily associated with typhoid fever, and of one no obvious cause could be ascertained. A detailed examination of the cases showed that the only link of connection between the greater number, which seemed likely to be concerned in the production of typhoid, was the community of milk-supply.

**PREVENTION OF OVERCROWDING IN TENEMENTS.**—In Glasgow all houses under a certain size are under police inspection. Every door bears a ticket marked with the number of cubic feet of space contained in the dwelling, and the number of inhabitants it is licensed to contain. Three hundred cubic feet of space is allowed for each adult, and 150 for each child. Ordinary dwellings and lodging-houses are distinguished by the shape of the ticket.

**SUICIDES IN FRANCE.**—Last year the number of suicides in France was 5,617, of whom 4,435 were men. Hanging was the measure resorted to by 2,500 individuals, 1,514 drowned themselves, 895 blew out their brains with firearms, 407 suffocated themselves with charcoal fumes, 129 swallowed poison, 154 threw themselves from public buildings, 13 elected to be cut to pieces under railway trains. The assumed causes, stated in their order of frequency, were as follows: Insanity, drunkenness, physical suffering, domestic trouble, fear of poverty. The greater number of suicides belonged to the class of peasantry.—*Lancet*.

## Original Lectures.

## DIABETES INSIPIDUS—FIBROUS PHTHISIS—TUBERCULAR MENINGITIS.

## A CLINICAL LECTURE

DELIVERED AT THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK CITY.

By FRANCIS DELAFIELD, M.D.,

ADJUNCT PROFESSOR OF PATHOLOGY AND PRACTICAL MEDICINE.

(Reported for THE MEDICAL RECORD.)

GENTLEMEN:—The case before us presents the following history. The child is now twenty months old. When six months of age, the mother first noticed that it passed more water than usual, and, at the same time, that it was very thirsty. At that time, the child also began to lose flesh and strength, and all these conditions have continued up to the present time. The child now passes about four quarts of water every twenty-four hours, an amount considerably too large for one of this age. The specific gravity of the urine has varied from 1,003 to 1,005. It contains no sugar. The appearance of the patient is better than one might expect after having passed such a quantity of urine for such a length of time.

We have to deal, then, with a case of the disease known as *diabetes insipidus*; simply an increase in the amount of urine passed, without the presence of sugar. The prognosis is very much better in such cases as this than in those in which sugar is present in the urine. We seldom see either of these diseases, *diabetes insipidus* or *diabetes mellitus*, in children at this age. We do see a simple increase in the quantity of water passed by children four or five years of age, but it is quite uncommon to find that condition present in children under one year of age. The prognosis in this case is not particularly bad. There is no reason why the child should not get entirely well. If, however, there was sugar in the urine, the prognosis would be particularly bad. True diabetes occurring in young children is a disease which is not at all amenable to treatment. This child has already been taking the valerianate of zinc combined with small doses of opium, and, although there has been some improvement in the general health, there has been but little or no diminution in the quantity of urine passed.

The two drugs which are most commonly employed in the treatment of this trouble in children—to diminish the quantity of urine discharged—are valerian and belladonna. The preparation which the child has been taking, the valerianate of zinc, is of service in some cases. The simple tincture of valerian answers a very good purpose not infrequently. I have, however, employed belladonna more frequently than valerian. It may be administered either in the form of extracts, or the plain tincture may be used. Of the extracts, I prefer the fluid extract, and especially in so young a child as this; it must first be administered in small doses in order to avoid the poisonous effects of the drug. In fact, instead of using the belladonna, I prefer its active principle, atropine, simply for the reason that it can be given in more minutely divided doses. I should, therefore, for this child have a solution of atropine prepared of the strength of one grain to the ounce, and of that I should give five drops once a day. Five drops of such a solution then will be administered and its effect watched. If no constitutional disturbance is developed, no complaint about the throat, no disturbance of the stomach or bowels, I should increase the remedy by giving five

drops twice daily. If no ill effects follow, it may be given three times a day, and in due time the size of the dose may be increased until six or seven drops are given, and repeated until the point of tolerance is finally reached. The physiological effect of the drug must be produced, as nothing short of that seems to answer the purpose. At the same time, it is very important that a child in this condition should take cod-liver oil. A teaspoonful may be given by the mouth three times a day, or if it does not agree with the stomach, the oil should be rubbed on the skin once a day. In some manner, either internally or externally, the oil should be administered. Besides, you should insist that the child be thoroughly washed every day with warm water and soap, be clothed with flannels which cover the entire body, and if the weather is pleasant, that the child be carried out-of-doors daily. If this can be done, the probabilities are that the child will get entirely well.

*Subsequent History.*—Atropine in doses of  $\frac{1}{100}$  of a grain was administered until a slight rash was produced, and also some dilatation of the pupil. The improvement was marked, and it was directed that the drug should be continued in such doses as would secure its "continuous" effect.

## PHTHISIS OF TWELVE YEARS' DURATION—REPEATED HÆMOPTYSIS.

This man, forty-two years of age, gives us the following history:

In 1864 he spat up a small quantity of blood. He had a cough at that time and some fever, but recovered and remained well for four or five years, when another attack came, and he raised about half a pint of blood. The man feels quite certain that he coughed the blood up. From that attack he recovered, and remained apparently well for a year and a half, when he raised blood in quantity somewhat larger than at any previous attack. From that attack he also recovered very rapidly, and seemed perfectly well at the end of a few days. He then was able to work for three and a half years. Last year, in March, he began to raise blood again in small quantities. He had a hemorrhage, ceased work for a few days, seemed well, returned to his work, raised blood again, and so the case went on until July, when he raised about half a spittoonful, as he says, and soon after about the same quantity. Since that time he has raised blood in varying quantities, not large, about every four weeks. At his last hemorrhage he raised only a small amount of blood. He has lost considerable flesh, and now feels too weak to work.

Such, gentlemen, is the history of this case, and it is not at all like that of ordinary phthisis. In the first place, it is difficult to be certain, from the man's statement, whether the blood has really come from the air-passages. If he has coughed it up—and he seems to be disposed to believe that such has been the case except in one instance—then the question arises whether it is simply hemorrhage from the bronchi, without lung disease, or whether he has more or less phthisis.

It is possible for a man to have hemorrhage from the bronchi the same as from the nose, and have repeated hemorrhages, without any lung disease. A physical examination, doubtless, will assist us in solving these questions.

*Physical Examination.*—It will be noticed, first, that this man is only moderately emaciated. There is a distinct epigastric pulsation. There is a diffused cardiac impulse, without distinct apex beat.

Percussion note is duller in the infraclavicular region upon the left than upon the right side. Sub-crepitant râles are heard over the point of dullness at

the apex of the left lung. Posteriorly, we find good respiratory murmur over the right lung, but fine subcrepitant râles over the left, although there is no dullness upon percussion. The case then is one of *phthisis*, and the point of interest in it is the long time which it has lasted. The disease probably began twelve years ago, and the man has had occasional attacks of hæmoptysis since that time; yet, with the exception of such attacks, has been in fair health. He has not had much cough, and for a considerable time after the commencement of the disease was able to work. I think there can be no question with regard to the form of *phthisis* this man has. It is that form in which the disease is confined to the interstitial tissue of the lungs without involving the air-vesicles. If we could look at the left lung of this patient, the greater portion of it would be found studded with small white or grayish, or blackish nodules, most of them not larger than the head of a pin; in places these nodules might be aggregated in patches. At the left apex we should also find, in addition, fibrous bands and patches of fibrous tissue extending through the lung and rendering it solid. This, quite certainly, is the anatomical condition of the left lung in this man.

Now, with regard to prognosis and treatment. Although the disease had advanced so far the prognosis is tolerably good. If the man takes proper care of himself he may live for a long time. The treatment is entirely constitutional. He might be benefited, perhaps, by a change of climate, and he should take tonics and cod-liver oil. No local treatment whatever is required.

#### TUBERCULAR MENINGITIS.

The history of this case is very straightforward. The child is a little more than three years old, and has always been healthy until one week ago, when she began to vomit, and the vomiting has continued daily up to the present time. She is not particularly restless, but manifests a desire, when on the bed, to get to the edge, so that her head can hang over. She does not pass water as freely as natural; indeed, has not passed any since yesterday morning. The only complaint the child makes is that she "is sick in the head." She has had some fever. The child's mother has suffered from some form of lung trouble, probably *phthisis*, but aside from that there is no trace of family taint. A case of *phthisis* can almost always be found somewhere in the family of one who has tubercular meningitis.

Such a case as this is rarely seen at a college clinic.

One week ago this child was taken sick rather more suddenly than the average of cases of tubercular meningitis. The ordinary description is that the child has been peevish and irritable for several days previous to the development of the more marked symptoms. This is the rule, but it is a rule which has its exceptions, and the case before us is one of those exceptions. In this case, the child, previously in good health, was suddenly seized with vomiting, and the vomiting has continued up to this date. Within a day or so after the child began to vomit, she began to have fever, and has had some febrile movement ever since. Exactly what the febrile movement has been we cannot determine, for no thermometrical record has been kept. The temperature in this affection, however, is not necessarily very high; there is no typical curve, perhaps, but it is very irregular. Sometimes it may be down to normal, and again it may rise as high as 103° or 104° F. In some cases the temperature will be no higher than 101° or 102° F. until the last days of the disease.

Besides the vomiting and febrile movement which this child has had, it will be noticed that it lies perfectly relaxed and looks as if asleep. It is not asleep, however, but is simply lying quietly with the head thrown back. If placed upon the bed it would lie in the position placed, and remain there indefinitely.

Such perfect apathy is quite characteristic of tubercular meningitis. In some cases this apathetic condition will alternate with periods of restlessness; that is, instead of lying quiet, the patient will be restless, move itself about, roll its head, cry out from time to time, and these spells of restlessness may continue for half an hour or an hour, and then the patient will lapse into this apathetic condition. This child, however, has not manifested this restlessness. There is no change in the pupils, but there is slight strabismus of the right eye. In some cases there is dilatation of one or both pupils, but in this case there is only the strabismus.

The slowness in passing the water is also quite frequent in these cases. You will observe that the child has not passed water in about thirty hours. This is not infrequently the case in this disease, and the children may not pass water for even three or four days. This is a symptom of less importance in children than it would be in adults. Children at this age have, as it would seem, a kind of fancy for not passing water when sick; they do not wish to pass water, even though the bladder manifestly contains a considerable quantity. Again, with different diseases of children there may be marked diminution in the secretion of urine for one or two days, without doing much harm. It is quite common, in tubercular meningitis, to find that the urine is passed with less frequency and in smaller quantities than normal. The vomiting, which has continued from the day of attack until the present time, the febrile movement, the pain about the head, the condition of permanent apathy, the strabismus, and the diminished excretion of urine, make up the symptoms of the case. The pulse is increased in frequency. The respiration has none of the peculiarity which is frequently developed in connection with tubercular meningitis—the sighing respiration.

Now, as to the length of time this child will probably be sick. There is little or no chance for recovery, and the question may be asked, how long will it be before death will take place? The probabilities are that the child will die within a week. The disease has appeared more rapidly than usual, and the cerebral symptoms are all very marked. As the child gets worse, the apathetic condition will become more and more marked until coma is fairly developed. The temperature towards the close of the disease will probably rise, the pulse will become more and more frequent, and the vomiting may continue up to the end, or it may cease at any time.

Now, as to the *treatment* of the disease. The treatment of these cases is very much biased by the peculiar views held by each practitioner regarding the possibility of recovery. My own opinion is that cases of tubercular meningitis never recover. I do not, therefore, care to disturb the child with any treatment calculated to cure the disease. I do not care to put blisters to the nape of the neck, or to adopt any active treatment whatever. It simply disturbs the child, and, in my opinion, has no good effect upon the disease.

For this child the only symptoms which may claim relief are the vomiting and the condition relating to the urine. The child is tolerably comfortable except for the vomiting and the diminished secretion of urine. I should be disposed, therefore, to give the simple effervescent draught (bicarbonate of potash

and lemon juice), which may serve the double purpose of acting as a sedative for the stomach and increasing the secretion of urine.

In order to still farther increase the secretion of urine, I should be disposed to give the child a hot bath; one to-day and probably repeated to-morrow. Let the child be placed in a tub of hot water for about five minutes, then be removed, and, without drying, be wrapped in warm blankets and allowed to sweat for two or three hours. It will probably pass water while in the hot blankets. This is one of the best means for making children pass their water that can be employed. When something is required to keep the patient quiet, a mixture of chloral hydrate and bromide of potassium is the best that can be employed.

If you entertain the idea that any effect can be produced in the way of retarding the progress of the disease, you will probably resort to counter-irritation and the use of iodide of potassium in such doses as may be deemed necessary.

*Subsequent History.*—The child died at the end of the fifth day after the above record was made.

## Original Communications.

### ON THE UNITY OR DUALITY OF SYPHILIS.

By F. N. OTIS, M.D.,  
NEW YORK.

A NEW contribution to the literature of this subject invites attention for the reason—if for no other—that the most learned, experienced, and impartial men in our profession are about equally divided in their opinions on the cardinal points which a discussion of it necessarily involves.

In an elaborate article, from the pen of Mr. John Milton, of London (which appeared in the RECORD, April 7th and 14th), the views of M. Melchior Robert, of Paris, a well-known unicist, are made the subject of attack. Mr. Milton goes back sixteen years to find a pure unicist, in the person of M. Robert, and states that his (Robert's) views would be found to cover all the essential points claimed by the unicist of the present day. This would seem to indicate either that during this time no progress had been made by unicists or dualists, in the manner or results of investigation of the diseases in question, or that the issues had degenerated into a political quarrel, in the course of which the tide of success or popularity had swayed from side to side in accordance with the partisan enthusiasm which the leaders were able to infuse into the rank and file. The latter view is suggested as most probable in the closing paragraph of Mr. Milton's paper, when, expressing his view on the present status of the subject, he says: "But the tide of reaction having set in towards unity it is doubtful whether any authority would have availed to check it, experience having shown that sometimes the only plan is to let the current exhaust itself."

Now, I for one am unwilling to accept a view so uncomplimentary to the intelligence and honesty of purpose of those who, for the last sixteen years and longer, have been discussing the *pros* and *cons* of the unity or duality of syphilis.

Mr. Milton brings before us M. Robert, as representing the School of Unity, to express the views of those who believe that syphilis and chancreoid are in the relation of parent and child. That, without syphilis as a progenitor, chancreoid would never have been brought

into existence, and that thus there is a necessary connection of *origin* between what often appears to be two separate and distinct diseases. Mr. Milton himself appears as the advocate of the opposing school, who believe the doctrine of *duality*, viz., that syphilis and chancreoid are separate in origin, separate in action, separate in results. Out of M. Robert's numerous points claiming to prove the doctrines of unity, Mr. Milton selects five to combat as follows:

1st. "That chancreoid, developed upon a person who has had syphilis, may communicate from this *chancreoid*." This position is claimed to have been established by clinical cases carefully observed, which are cited. These cases of M. Robert's are confronted by other clinical cases, also observed with care, in the practice of Mr. Milton, proving the fallacy of M. Robert's conclusions.

2d. "Chancre is capable of communicating chancreoid, which is not followed by constitutional syphilis." This position is also supported by clinical observation, the correctness of which is called in question and the conclusions rejected politely by Mr. Milton.

3d. "Auto-inoculation of a suppurating bubo" (presumably chancreoid) "may be followed by a hard sore and by constitutional syphilis." This is likewise objected to as without force in view of incompleteness of observation, and the known (from clinical observation) eccentricities of chancreoid sores.

4th. "Chancreoid contracted from an individual suffering with syphilis, and not followed by syphilis, may communicate syphilis, to a third person." Supported by clinical observation, this is combated by citation of numerous cases in the public and private practice of Mr. Milton, and which go to show that M. Robert is wrong in his inferences if not in his premises, and this is farther supported by the quoted observations of Mr. Fournier, Dr. Bumstead, and M. Diday.

5th. "From the same source of contagion, chancre and syphilis may be communicated to one person (presumably healthy), and simple chancreoid to another." This is not accepted by Mr. Milton as bearing upon the question of unity at all. Then follow about a dozen "*theorems*" or positions held by M. Robert in favor of unity and substantiated by clinical cases, and these "*theorems*" are squarely rebutted by the cited results of clinical observation in the practice of Mr. Milton, and by close and cogent reasoning therefrom are shown to prove the falsity of M. Robert's deductions, and to establish beyond question the doctrines of duality. Mr. Milton, with all this, accords to M. Robert the position of an able observer and an amiable antagonist.

Now, while I would not for a moment call in question the soundness of Mr. Milton's views, nor the logical correctness of his deductions, I would say that we have in his article simply a repetition and a very good example of what has been going on in the medical profession here and abroad for the last forty years, viz., a series of *clinical* observations, which are brought forward to prove certain doctrines, and these pitted against similar observations and deductions, which are cited to prove diametrically opposite doctrines; and thus we are to-day, inclusive of Mr. Milton's article, relatively in the same position—not one whit nearer agreement, as a profession, in the matter of unity or duality, than in the beginning of the contest forty years ago.

Is it not, then, time that some other methods of getting at the absolute truth of the matter were generally adopted? Clinical observations, which have been thus far almost solely relied upon for the solution of the *questio vexata* of venereal diseases, are as a rule

made under such peculiar embarrassments, moral, mental, physical, and circumstantial, that the same apparent conditions falling under the notice of one observer often present phases and peculiarities in the practice of another that warrant entirely different conclusions, and hence it is that, notwithstanding that the diseases syphilis and chancreoid have been studied by numerous earnest, honest, and competent observers for a very long period, wide and sincere differences of opinion exist in the matter of unity and duality. These can never be completely settled until some other and more philosophic mode of arriving at conclusions shall be adopted than that offered by clinical observations alone. To this end the *science* of the subject demands our attention, more especially as the great advances in general and minute physiology and pathology have within the past few years rendered it possible to understand and appreciate the true nature of many morbid conditions and processes, which no amount of ability, earnestness, or research could have deduced from clinical observation alone.

*Biesiudecki* has shown by careful microscopical examinations of chancre and chancreoid that there is a difference in the histological condition of these lesions. Throughout a large number of observations he has found that, in every examination of a section of undoubted uncomplicated *chancreoid*, the appearances were identical with those of *simple ulcerations*, while in his examinations of the *true infecting chancre*, relatively, a greatly increased accumulation of the white corpuscular element was found. That while in the chancreoid the usual *inflammatory* accumulation of white blood-cells in the tissue, and surrounding the blood and lymph vessels (as is characteristic of the simple inflammatory process), were found, the interior or lumen of the vessels was quite free. In the true chancre, in addition to the usual inflammatory cell accumulation in the perivascular structures, the *interior or lumen* of these vessels was *packed* with the white cells to the extent of obstructing the circulation through the vessels, and that thus a distinct dryness as compared with the chancreoid tissue was present, and this sufficient to be characteristic, and in some measure at least to account for the induration recognized as diagnostic of the chancre or initial lesion of syphilis.

Kaposi, a unicist, has recognized the same peculiarity, viz., the invasion of the lumen of the vessels by the increased proliferation of white blood-cells as compared with chancreoid, although he has not accepted it as a diagnostic difference. What would naturally be inferred from these histological discoveries? One thing certainly, viz., that in the chancre there was an increased accumulation of white blood-cells as compared with that occurring in the chancreoid. Does not this indicate a difference in the processes which produce the chancre and the chancreoid? In the chancreoid we have only the cell-accumulation, which is recognized as characteristic of ordinary inflammatory action. In the chancre we have *something more*; we have apparently an increase of *growth*, or a proliferation of the white blood-cells or germinal elements. Now what have we as the *characteristic* of the *chancreoid*? It begins as an *inflammation*, which goes *directly* on to *ulceration*—to *destruction* of tissue. Without ulceration there is no chancreoid. The pure, uncomplicated chancre is a *popule*, a proliferation of white blood-cells; this excessive growth and accumulation of cells is the first evidence of the disease, is the characteristic of it, and the excessive accumulation of cells is the characteristic of every manifestation throughout the entire course of syphilis. On the con-

trary, the characteristic of the chancreoid is *destruction*, death of tissue. Without destruction of tissue there is no chancreoid. It may also, I think, be claimed that without *proliferation* of cells there is no chancre. The one, then, is a process of *destruction*, the other a process of *growth*. The chancreoid is an ulcer; its characteristic action is destruction. From its inception it exhibits the destructive tendency. A molecule of the chancreoid virus, applied to an abrasion of the skin or mucous membrane, sets up an inflammatory action *at once*, which goes on steadily to the destruction of tissue. Pus is its primary and legitimate product. Pus, which if inoculated on a healthy surface, sets up a similar destructive action, and this continues during the existence of the lesion. Now let us inquire as to the significance of this destructive action. Is it a process *sui generis* due to a specific influence, only capable of being established by a chancreoid element or principle, or is it in line with vitiated natural processes, capable of being established by other causes? Pus from a simple acne, as has been shown by Pick, Kaposi, Roeder, Zissel, Wigglesworth, and others, may, by inoculation on a subject free from syphilis, produce a sore which cannot be distinguished from the chancreoid. It has the property of destruction, the power of being repeated in successive generations. Kaposi says: "My own experiments have taught me that non-syphilitic pus, such as we find in acne and scabies pustules in non-syphilitic persons, when inoculated upon the bearer as well as upon other non-syphilitic persons, produces pustules whose pus proves to be inoculable in generations; that loss of substance was caused by the pustules, which healed by cicatrization, and that with the increase of the number of pustules produced by the inoculations, the contagiousness of the pus diminished, and finally became quite extinguished. Is not this the description of *chancreoid*? And if this process, which appears to be identical with chancreoid, can be set up in persons free from syphilis, and without the influence of syphilis, most certainly it is *not* syphilis. Chancreoid, or lesions identical with it, then, is a process of *destruction* of tissue capable of being set up by various causes. Syphilis is a process of proliferation, and may be developed independently of the ulcerative action—*may* proceed throughout its course without the ulcerative action. Is it not, then, fair to conclude it is a disease independent of chancreoid and its congeners, which are characterized by the destructive property alone? It can be shown conclusively that the one is a destructive process, the *chancreoid*—the other a process of proliferation of growth, the *chancre*. If by chance they are associated, they are only associated as life and death are associated. This is the only legitimate and logical conclusion that can be deduced from the premises, and can these premises be disputed? Certainly only by *scientific investigation*, not by clinical observation, which alone, as has been shown, is beset with many elements of error and uncertainty. This one idea is inevitable, in the light of past experience, viz., that no amount of clinical observation, or deduction from any clinical observation, can avail in determining the truth in regard to unity and duality. Nothing but careful microscopical research and analogical reasoning can be relied upon to solve the vexed question of unity and duality.

108 WEST THIRTY-FOURTH ST., MAY 8, 1877.

SICK-HEADACHE.—Dr. H. W. Hendrick, of Hyde Park, Vt., has had excellent success in the treatment of sick-headache, by guarana in powders, grains five to fifteen for a dose.

## Reports of Hospitals.

### HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA, PHILADELPHIA.

AN ABSTRACT OF MEDICAL CLINICS. DELIVERED AT THE HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

By DR. WM. PEPPER,

PROF. OF CLINICAL MEDICINE.

(Reported by SAMUEL M. MILLER, M.D.)

#### CHRONIC INFLAMMATION OF THE BOWELS.

THE patient, a man thirty-four years of age, dated his symptoms back to the years 1861-65, when he served in the army. The troops were at that time encamped in swampy ground, and nearly all of them suffered from the effects of bad air and water, frequently complicated with malaria. This often brought on a chronic follicular catarrh of the small intestines, followed by an enlargement of the solitary glands and to a less extent of Peyer's patches, a thickening of the coats of the bowels, and the discharge of increased secretions. This was the usual type of camp diarrhoeas. The man's more recent sickness began with a violent attack of vomiting and purging, which occurred about two years ago. Ever since that time he has suffered from severe attacks of diarrhoea, lasting generally from three to four days at a time, and attended with violent griping and vomiting, and sometimes as many as nine passages daily.

We meet with such cases originating from very varied causes; in some instances occurring among the young, apparently from a morbid predisposition to irritation of the intestinal mucous membrane; in others evidently produced by causes connected with the occupation or habits of the individual. They are not rarely met with in women after the cessation of menstruation, where they seem to be due to irritation set up by the accumulation of matters previously regularly discharged. In those who are the subjects of chronic catarrh of the intestine, the causes which produce such sudden attacks as above described are often inconceivably slight, such as draughts, indiscretion in diet and clothing, anxiety, bad news, etc. The attacks generally last from one to three days, and are always paroxysmal in their nature.

In the management of such cases individual symptoms must be borne in mind. The food taken should be thoroughly assimilable. Alcohol, green vegetables, fruits, and much solid meats should be refrained from. Buttermilk, beef-juice, milk, with lime-water, and light farinaceous foods are the safest articles of diet. The clothing should be amply sufficient, and all excessive exposure avoided. In the matter of medicines, the proper mode of treatment is that by alteratives and astringents. Among astringents the best are nitrate of silver, bismuth, the astringent salts of iron, and lead. If the diarrhoea be very marked, opium may be joined with the astringents. Dr. Pepper generally prescribes nitrate of silver in pill form, one-third of a grain from one to two hours after meals. The treatment must be long persevered in to effect a permanent cure.

#### CHRONIC ARTICULAR RHEUMATISM.

In the first case, that of a sailor-boy, the rheumatism, which was at first general, had become concentrated under the instep and in the sole of the foot. Its effects were intensified by the extreme natural flatness of the foot, which threw all the weight of the

body on the instep and on the middle of the sole, where the tissues were as thick and as hard as under the heel. There was much ankylosis of the joints, and the plantar nerves were pressed upon and irritated by the indurated tissues.

The successful mode of treatment has been by manipulation of the ankylosed joints and counter-irritation applied to the nerve-trunk higher up the leg. The continued current with the positive pole placed over the point of tenderness, and the negative pole higher up the nerve, may also be employed. A shoe should be constructed which shall take the strain off the painful point and throw the weight of the body on the outside of the foot. Iodide of potassium may be given internally.

The second case, rheumatism of the ankle-joints in a young girl with a rheumatic diathesis, was brought on by scrubbing in her bare feet. The girl was able to notice the curious fact that *the pain and soreness always increased before and during bad weather.*

The persistent use of iodide of potassium was followed by the best of results. Dr. Pepper recommends highly the use of Zollikoffer's mixture in such cases, viz.:

B. Pulv. resin. guaiaci..... gr. x.  
Potas. iodidi..... gr. x.  
Tiuc. colchicis sem..... f̄ ʒ ss.  
Aq. cinnamomi,  
Syrupi, aa q. s. ad..... f̄ ʒ i.

S. A dessertspoonful to a tablespoonful thrice daily.

#### ACUTE GASTRO-HEPATIC CATARRH.

This was one of those highly deceptive cases which display many of the symptoms of a malarial fever, but refuse to yield to large doses of quinia. It proved to be a sympathetic fever connected with a local lesion of the gastro-intestinal mucous membrane. In acute cases the symptoms of gastric and hepatic disturbance may be very marked, as in the present instance; while in more subacute cases the irritation is more obscure, and yet keeps up irregular febrile symptoms, often of a quotidian type. In the case of this patient, finding that the evening exacerbation failed to yield to large doses of quinine, the treatment was stopped on the ninth day of the attack (the third day of treatment), and five grains each of the subnitrate of bismuth and the bicarbonate of soda were given every three hours; while at night a mild mercurial laxative, followed next morning by a small dose of Rochelle salts, was also administered. The diet allowed was very light. The case at once came under control. The temperature was reduced to 98½, and the gastric symptoms disappeared.

In the general treatment of such cases, if their malarial nature be suspected, it is well to begin with full doses of quinia. If, however, the gastro-hepatic symptoms are prominent, the quinine treatment should be postponed for twenty-four hours, and five to ten grains of blue-mass should be administered and followed by a saline. Then, when the liver and stomach have been well acted upon, begin to give quinia by the rectum, so as to avoid gastric irritation. Four suppositories of five grains each may be given at intervals of two or three hours. If the febrile action of irregular type is not subdued soon, we may suspect that it is maintained by the local irritation of the mucous membrane, and the case is to be regarded and treated as one of gastro-hepatic catarrhal fever. The diet should be restricted, and febrifuges and subacids given, and the skin sponged with cold water if the fever be severe.

## GRAVES' DISEASE.

The patient was a woman of fifty-six years, who had her "change of life" two years ago. She was suffering from anxiety, disturbed cardiac action, extreme nervousness, uterine troubles, and exophthalmos, with enlargement of the thyroid gland.

The disease is most common in young women of a nervous type, though it occurs in males also. It may, indeed, be developed in any one subjected to influences which impair nutrition and disturb the nervous system. It is thus that, as in the present case, it may be met with in women about the menopause. The prominent symptoms are: (1) protrusion of the eyeballs, exophthalmos; (2) enlargement of the thyroid gland; and (3) disturbed cardiac action. To these are often added anæmia, and nervous and uterine disturbances. The degree to which these various elements exist varies in different cases. The exophthalmos and goitre may be exceedingly marked, or scarcely perceptible. The disturbance of the heart's action is generally functional and very marked, with an exceedingly rapid pulse, running from 120-150 in the minute, and sometimes, as in this case, a musical, systolic, blowing murmur, heard over the pulmonary arteries, and anæmic in its character. There is in such cases a morbid action of the sympathetic nerves, and a weakened state of the blood. In some instances extreme throbbing of the vessels of the neck, and perhaps a thyroid thrill, can be noticed.

The treatment of this disease is by good food, rest, sunlight, exercise, and complete release from cares. Among medicines the best are iron, arsenic, digitalis, bromide of potassium, and ergot.

## LUMBAGO.

The patient, a young married woman, was confined five months ago. Two days after her confinement she complained of pain and stiffness in the lumbar region. During the week following her confinement her elbows and ankles were swollen, and she had an attack of acute articular rheumatism. These symptoms came on suddenly and apparently without any cause. The patient now has a slight systolic, mitral murmur, possibly functional, and complains of shortness of breath and dizziness. Stooping gives her great pain in the affected region, and she does not bend the lumbar spine at all in the act. Pressure upon the spinous and transverse processes of the lumbar vertebrae also causes great pain. The name lumbago is given to this condition. It is essentially understood to imply rheumatism of the lumbar muscles. Evidently, however, while in some cases the fibrous elements of the muscle are alone affected, in other instances there is also an inflammation of the sheath of the muscular nerves; and in still others of the periosteum of the bones adjacent. In some cases, also, the small joints between the vertebral processes may be involved, and even lead to ankylosis. In the present case it seems that, although the mass of erector spinal muscles is involved, there has also been an implication of the periosteum of some of the intervertebral joints.

The treatment in this case should be manipulation applied to the lumbar region of the spine, so as to restore mobility. To subdue the painful condition of the muscle, injections of  $\frac{1}{16}$  of a grain of atropia and  $\frac{1}{2}$  of a grain of morphia, well diluted, should be made well into the body of the muscle. [This is the usual treatment of local rheumatism at this hospital, and it has been followed in all cases with most gratifying results.] Great care must always be had in the administration of morphia and atropia to nursing

women, as belladonna is the most powerful anti-galactagogue known, and too large doses of morphia not unfrequently affect the child through its milk. As regards other methods of treatment, the local application of blisters, iodine, and croton oil, together with the internal administration of iodide of potassium, will often do good.

## ULCER OF THE STOMACH.

A specimen of the stomach of a man who had just died of severe and repeated hæmatemesis was exhibited to the class, showing two ulcers of considerable size. One of these was found to have perforated the mucous and muscular layer. This complaint is very common in women, especially among the young. The causes are various and well known. In the instance under consideration the spleen was found to be unusually enlarged—probably the result of a previous attack of malarial fever—its fibrous elements being thickened and the malpighian corpuscles hypertrophied. The ulceration was evidently brought on by the turgescence of the blood-vessels of the stomach, produced by the obstruction of the splenic circulation.

The treatment of gastric ulcers is by astringents. Nitrate of silver, in the form of pills, should be given in full doses after meals. Among other remedies, the persalts of iron, the subnitrate of bismuth, and the sulphate of copper are useful. If there be much pain, opium, hydrocyanic acid, and chloroform may be administered. An exclusive milk diet is preferable. Beef-juice, gruel, and arrowroot can be taken with safety. All solid food must be avoided. At the time of hæmorrhage, absolute rest must be insisted upon; pieces of cracked ice should be swallowed; Monsell's solution, tannic or gallic acid should be given internally; morphia may be given by the mouth and ergotina hypodermically, and all food must be administered by enemata for the time.

## AN OBSCURE CASE.

A very obscure and interesting case. A well-grown girl of seventeen, with no known hereditary tendencies. The examination, made before the class, disclosed great exophthalmia, though the patient said that her eyes were naturally prominent; a very general anasarca, shown in œdema of the feet and legs below the knees, of the vulvæ, and of the abdomen between the genitals and the umbilicus. There was no tumor in the abdomen, and careful percussion failed to reveal any considerable amount of fluid in the peritoneal sac. The skin and connective tissue of the vulvæ and abdomen were extremely painful to the touch. Though seventeen years old, the girl had never menstruated, and there was no hair on the external genitals. Accompanying the œdema there was very marked turgescence of the veins all over the body, particularly those of the face and abdomen. Physical examination of the chest showed the signs of pulmonary congestion, with bronchial catarrh—namely, sonorous, sibilant, and crackling râles. The great increase in resonance over the back of the lungs indicated a decidedly emphysematous condition of the lower lobes. The sputa were white and frothy, and occasionally contained blood. There was no solidification of the lungs, and no dulness on percussion. The possibility of phthisis was precluded by the absence of the usual signs, and of night-sweats, and loss of flesh. The heart sounds were perfectly normal. The pulse but slightly increased in frequency. The tongue was heavily coated. The bowels regular, but the appetite very poor. The girl was never very strong, always suffering from shortness of breath, and

her nutrition has never been good. She has no work to do, sleeps well, and eats good food. She has had two attacks of dizziness within the past three weeks, during which, though she did not fall to the ground, her face became purple, she lost consciousness, and her hands were clenched. There was no jaundice. Her tonsils were hypertrophied, and she has suffered occasionally from difficulty in swallowing. There have been no symptoms of disturbed digestion. All the œdematous parts pit on pressure. On lying down there is great lividity of the face and enlargement of the veins. All these symptoms, together with a very racking cough, have developed within the past six months.

The first thought that comes in studying this case is that it is one of chronic disease of the kidneys. The bronchial symptoms, general anasarca, venous congestion, and epileptiform attacks are all suggestive of chronic nephritis. But a careful examination of the girl's urine has failed to reveal the presence of any albumen, and, according to her own statements, she never is obliged to rise at night to pass water, has no pain in her back, has never had difficulty in passing water, and has noticed no change of late in the quality, quantity, or color of her urine. A thorough microscopical examination of the urine has shown no tube casts, no unusual amount of epithelium, and only a slight increase in the normal number of uric acid crystals. The specific gravity of the urine was 1016, and the color normal.

[I will send, on a future occasion, the result reached after further study of the case, together with the treatment employed.]

## Progress of Medical Science.

**THE SOMATOSCOPE.**—Dr. V. Huter, of Marburg, has designed a new instrument, to which he has given the above name. It comprises a stethoscope, a percussion-hammer, and a pleximeter in one instrument, and the advantage claimed for it is that it does away with the necessity of carrying three separate instruments in the pocket. When complete, it resembles the ordinary monaural stethoscope, except that the head of the hammer projects from one side beneath the ear-piece. The ear-piece can be screwed out and used as a pleximeter, while the lower part of the stethoscope serves as handle for the hammer.

**JABORANDI AND HOARSENESS.**—Dr. Eyselain, of Blankenburg, recently administered 45 grs. of jaborandi to a lady who was suffering from hoarseness and pain in the neck due to a cold. The leaves were powdered, and a cupful of boiling water poured over them; after standing fifteen minutes, the decoction was sweetened and was administered at 8 P.M. After a few minutes, the patient experienced an agreeable sensation over the entire body, which was rapidly succeeded by strong, general pulsation, nausea, vomiting, fleeting pains in the abdomen, especially over the region of the bladder, and an outbreak of abundant perspiration. These symptoms were accompanied by great general discomfort and extreme prostration. The perspiration continued for about two hours, and the bed linen was soon soaked through. Three times during these two hours sudden chills set in, the body, face, and extremities becoming cold for a time. The perspiration was accompanied by a very profuse discharge of saliva; soon after they began, the hoarseness disappeared entirely and did not again return.

In consequence of the general lassitude the patient soon fell asleep, but the saliva continued for a long time to run out of the corner of the mouth. The perspiration did not involve the hairy parts of the head. On the next day, the patient complained of weakness and lassitude; the left submaxillary gland was somewhat enlarged and tender, the appetite poor, and the saliva thick.

This case shows the necessity of caution in the administration of large doses of jaborandi, although the dose was 15 grs. less than is ordinarily given to an adult at a single dose. The effect on the hoarseness was all that could be desired, but it was attained at the cost of very great discomfort.—*Allgem. Med. Central Zeitung*, March 21, 1877.

**HEMORRHAGIC MALARIAL FEVER.**—In a paper published in the *Richmond and Louisville Medical Journal* for March, Prof. Joynes, of Richmond, retracts the opinion, formerly expressed by him, that the discoloration of the urine in this disease is due to the presence of bile pigment. Numerous observers in the Southern States have in late years found blood-corpuscles in much the larger proportion of the specimens of urine from this disease that were examined. In one case of the disease that came under his own observation Prof. Joynes found blood-corpuscles in the urine on microscopical examination, and the chemical tests yielded satisfactory proof of the presence of blood. In several specimens from two other cases, which were sent to him from a distance, he found no blood-corpuscles, but heat and nitric acid produced the dirty-brown coagulum of albumen and hæmatin; in all these specimens, however, the urine was ammoniacal, and it is a known fact that blood-corpuscles very rapidly disintegrate and disappear in this condition of the urine. In none of the specimens of urine examined by Prof. Joynes did nitric acid give any indications of the existence of bile pigment. Once in the field of the microscope he saw a body which presented the appearance of a convoluted knot of capillaries, as if one of the malpighian bodies had been exfoliated from the kidney during the intense congestion of the febrile paroxysm. Prof. Joseph Jones saw this extraordinary appearance in one of his cases.

Although the urine in hemorrhagic malarial fever undoubtedly contains blood, it does not follow that the red corpuscles hold the same proportion to the other constituents of the blood in the urine that they do in healthy blood, or even that any of them are necessarily present when albumen and hæmatin are demonstrably so. Many competent observers believe that in this fever, especially in the graver cases, either under the direct influence of the malarial poison, or under that of the biliary matters contaminating the blood, a disintegration or solution of the blood-discs takes place, whereby the hæmatin is set free in the circulation; it then finds an outlet through the kidneys, and on examining the urine, while much albumen and hæmatin may be present, but few or even no blood-discs may be found. This is analogous to what takes place in septic, pyæmic, and putrid fevers, and in some extreme cases of scurvy. In the disease under consideration hemorrhages from the stomach, bowels, and other organs are of frequent occurrence, and it is a common thing for blisters to fill with bloody serum.

Prof. Joynes does not deny that bile, or at least its coloring matter, is present in the urine of hemorrhagic malarial fever, but simply states that nitric acid failed to reveal its presence in the specimens examined by him. It would be strange indeed if it were not generally present in greater or less quantity, considering the ex-

trème intensity of the jaundice. This jaundice appears suddenly while the liver is pouring out bile in profusion, and no obstacle exists to its free passage into the alimentary canal, from which it is abundantly discharged by vomiting and often by purging. It is almost unquestionably of hæmatogenous origin, and due to the disintegration of the red corpuscles and the transformation of the freed coloring matter circulating in the blood into bile coloring matter.

**ON THE RADICAL TREATMENT OF UTERINE CANCER.**—Prof. Goodell, of the University of Pennsylvania, believes that it is not only often impossible but is clinically needless to distinguish *intra vitam* the various kinds of uterine cancer. He believes that cancer of the uterus is of all cancers the least prone to infect the system; its victims die not so much from specific systemic poisoning, and from transference to distant organs, as from septicæmia, from embolism, and from the exhaustion induced by pain, sleeplessness, and the bloody or serous fluxes. In cancer of the cervix the indications are either to eradicate the disease, or failing in this to check the excessive discharges, to correct the fœtor and to allay the pain, and thus to prolong life. To effect this he advises removal of the cervix either by the *écraseur* or galvanic cautery. When the entire cancerous mass is not removed by these means, the remaining outgrowths and the underlying infiltrated tissues must be dug out with the finger-nails, scraped off with Simon's spoons, or snipped off with scissors. The resulting deep and funnel-shaped cavity must next be cauterized with fuming nitric acid or the hot iron. This may be done either at the time of the operation or after an interval of a week or so. During the operation, if scraping be needful, the hemorrhage is usually quite free, but in Prof. Goodell's experience it has always yielded to an injection of one part of Monsel's solution to three of water, followed by a sponge tampon lightly packed into the funnel-shaped pit. After the operation there is sharp fever for four and twenty hours or more. On the third or fourth day the discharges sometimes become offensive, and continue so for several days. After the scraping process the stench is invariably overpowering and must be met by injections of a solution of permanganate of potash, and by large doses of quinine to guard against blood-poisoning.

In all his cases Prof. Goodell enforces sexual abstinence, and orders the patients iron and bichloride of mercury as a tonic, arsenic to repress the tendency to reproduction of the new growth, and ergot to diminish the supply of blood to the uterus. He has now operated on thirteen cases, in all of which life was lengthened and made bearable; in one instance, as he believes, saved for good. The hemorrhages were stayed, the putrid discharges checked, the pains allayed, and the appetite restored, and bed-ridden patients were enabled to get up and resume their household avocations. Even when the womb was fixed by the extension of the disease to parts beyond operative reach, much was gained by removing all of the cancer that could be reached. The complexion invariably cleared up after the operation, and this fact leads Prof. Goodell to think that the so-called cancerous cachexia is due not to a cancerous diathesis, but to absorption from a local cancerous deposit.

Injury to the peritoneum cannot always be avoided during the operation. Karl Braum, however, does not hesitate to include a portion of the peritoneum in order that the hot wire may pass through perfectly healthy tissue. He says he has repeatedly in this way opened into the peritoneal cavity without harm to the patients.

In one case, while scraping with the finger nails, Prof. Goodell opened into Douglas's cul-de-sac. No vaginal injections were used, no untoward symptoms arose.—*Med. and Surg. Reporter*, March 10th.

**PROGRESSIVE PERNICIOUS ANEMIA TREATED BY TRANSFUSION.**—Mr. T. R. Glynn, of Liverpool, reports the following case: John F., age 42, engineer, admitted Nov. 15, 1876, into the Liverpool Royal Infirmary. He had always enjoyed excellent health until September, 1875, when he found that he was losing strength and becoming pale and thin; that his breath was short and his heart beat violently on any exertion. On admission he was greatly emaciated; his face was colorless, lips pale, feet and ankles œdematous; pulse soft, 90; respiration hurried, especially on exertion; temperature normal; urine normal in quantity; sp. gr. 1012, contained no albumen. Physical examination: splenic dulness somewhat increased; hepatic dulness normal; loud systolic murmur over base of heart and vessels in neck; impulse not displaced. On microscopical examination of the blood, the white corpuscles were found to be not increased in number; the red corpuscles were decidedly diminished in number, but regular in shape. The patient complained of great weakness, frontal headache, dizziness, impairment of vision and hearing, numbness of fingers, loss of appetite, etc. His condition rapidly became most serious in spite of energetic treatment. Bronchitis set in, and the cerebral symptoms pointed to the risk of sudden and fatal syncope. Under these circumstances transfusion was determined on as a last resort, and it was performed on Dec. 20th. The blood was conveyed from the vein of a healthy man directly to that of the patient by means of Aveling's instrument. The operation lasted about thirteen minutes, and between eighteen and twenty ounces were injected. As soon as the patient manifested uneasiness, the transfusion was stopped; he complained then of a sense of oppression about the chest, but in a little while became more comfortable. The operation was followed by a rise of the temperature, which reached its maximum (103° F.) on the next day, and also by an aggravation of the bronchitis. Ten days after the operation the patient was allowed to get up, and three weeks after it he began to take out-door exercise. He was subsequently sent to the Convalescent Hospital, where for some time he continued to improve. Then the old symptoms gradually returned, and he went home and died about two months after the transfusion. Mr. Glynn regrets that he did not return to the Infirmary, and that transfusion was not again practised.—*The Lancet*, March 31, 1877.

**A NEW JOURNAL.**—The first number (January, 1877) of the *Commentario Clinico di Pisa* has just reached us. It is a monthly octavo of forty-eight pages, of which thirty-eight contain original matter, principally clinical, including an interesting case of catalepsy in a man, and a critical study of uterovarian amputation. It is edited by Drs. Bardozzi, Fedeli, and Nerozzini.

**LIGATURE OF EXTERNAL ILIAC ARTERY.**—Prof. James R. Wood, M.D., ligated the external iliac artery at Bellevue Hospital, May 16th. The patient was a negro, who had been cured of a popliteal aneurism six months before, and who since then had an aneurism developed high up on the femoral of the same side. The operation, which was the eighth of its kind performed by Dr. Wood, was done by Sir Astley Cooper's method.

## THE SCHOOL HEALTH BILL.

SENATOR GERARD's school health bill, which passed the Senate several weeks ago, has finally been reported to the Assembly by the appropriate committee. As it must before long be placed upon its final passage, we hope that the legislators will be prepared to vote understandingly. It is useless to disguise the fact that there has been and is still opposition to the measure. But coming as it does from the Board of Education, the animus can be reasonably well understood. A correspondent in one of the daily papers, speaking on the authority of a gentleman who is adverse to the bill, states that a free conference with the different school-trustees has resulted in a verdict of condemnation to sanitary supervision, that the schools are already well inspected, that the bill is not only unnecessary, but, if passed, its operation will be a positive nuisance, by an interference with an already well-established and efficient system. This is so absurdly false in every particular that it would be unworthy of notice, except that it evidently receives the tacit and willing sanction of the Board of Education.

It is hardly necessary to repeat what has so often been said before in regard to the want of sanitary inspection in our schools. The officer who is now detailed for that purpose is mainly occupied in examining classes in the grammar departments, and even what little insight he may gain by these means into the sanitary condition of the scholars is entirely lost in the primary departments, which are not visited at all. We speak from what we know. The facts upon which such statements are based have been repeatedly presented to the public, and have thus far never been questioned. If the Board of Education desires to give itself any particular credit for what has thus far been done in the way of improving ventilation, preventing crowding, reducing the danger of

propagating contagious disease, it can make but a poor show. An inspection to-day of any of the schools, especially in the primary departments, will still show to a greater or less extent the same abuses of sanitary regulations which existed years ago. Even in the newly constructed school-houses no advantages have been taken of previous experience of defects. The ventilating apparatus is as useless as ever; water-closets are in close proximity to class-rooms, and not infrequently the noxious gases produce actual sickness during recitations. Notwithstanding the observations of Agnew, Loring, and others, that sufficient and properly managed light is necessary for the preservation of the sight, no alterations have been made to meet the given requirements. The abominable farce of calisthenics is still carried on in the primary departments, the hours of confinement are still the same, and contagious diseases are still spread without any apparent effort to check them. In the face of these facts, we are informed, on the authority of such as pretend to know what is required in our public schools, that there is no necessity for any change, in fact that any attempt in that direction would be decidedly mischievous. We do not pretend to say that sanitary inspection will accomplish everything, but we believe that the principle has been strongly enough advocated by the medical profession to at least merit a trial, the Board of Education to the contrary notwithstanding. We hope the bill will be freely discussed. The more our legislators ascertain the facts in the case, the better prepared will they be to vote. The arguments in favor of the measure are so numerous, that all serious opposition to it gains its strength only by studied misrepresentation.

Again we repeat, in behalf of the medical profession, whose good opinion on this subject is a unit, that we hope the bill will pass.

## STATE BOARDS OF EXAMINERS AND MEDICAL REGISTRATION.

It seems now that we are to see a new effort made by the civil and medical authorities of the State jointly endeavoring to regulate the practice of medicine within its territorial limits. We have at various times maintained that each State should exercise supervision over the granting of certificates or licenses for practice through its regularly constituted Medical Society, which should have in charge the examination of candidates for their degrees or licenses. We have repeatedly insisted that the colleges are not in a position to exercise this power, as, according to their present organization they are not interested in maintaining as high a standard of qualifications for practitioners as the public demand.

We are glad to see that good examples are set us in the West as well as in the East. The progressive State

of California evidently appreciates the desirable end to be reached, and is moving towards it with commendable vigor.

An act was passed last year by the Legislature directing each incorporated medical society to appoint a Board of Examiners to inspect diplomas and to issue licenses after examination to all practitioners of medicine who shall have shown themselves duly qualified. As the act includes "each State Medical Society incorporated," it is doubtless meant to embrace in its provisions any regularly constituted medical bodies, though they may be Homœopaths or Eclectics, and perhaps this is what we have to expect, for, according to the average legislative mind, they all have about the same right to recognition and protection as ourselves. A careful reading of the several clauses of the act shows that they have been somewhat loosely framed, and might be desirably amended in some particulars, and yet the State Medical Society deserves high praise for its promptitude and energy in carrying out the scheme, and so placing it fairly before the profession.

We are of course sorry to see that an applicant having a fraudulent diploma or one unlawfully obtained shall merely pay the nominal fee of *twenty dollars*, and that the verification of the diplomas shall consist merely in the affidavit of the holder and applicant that he is the lawful possessor of the same.

It would appear that this special leniency was designed to protect some one, and gives sad evidence of the slight amount of criminality which is thought to attach to the holders and owners of fraudulent papers. However, we see that from the first of the present year matters have all been changed, and that any one "filing or attempting to file as his own the diploma or certificate of another, or a forged affidavit of identification, shall be guilty of a felony."

The sale and purchase of diplomas, which we take it from a recent advertisement in one of our metropolitan journals still goes on, will receive something of a check, and the law will mete out proper punishment to those who offer them to others as official certificates.

The act further provides that from the same date no certificates shall be granted except to holders of "diplomas or licenses from legally chartered medical institutions in good standing."

Then as now all the names of practising physicians and surgeons shall be registered in the office of the County Clerk, and shall be open to inspection during business hours. Itinerant vendors and the like are to pay a license of one hundred dollars a month.

The Board of Examiners of the State Society may properly be congratulated on the good work they have done, and Dr. Grover, their Secretary, in particular, for the pains and expense he has personally incurred in furnishing the profession with a full list of those whose qualifications the Board has duly attested. The catalogue of this year, just issued, contains over

a thousand names, with residence, date of diploma, name of institution, and number of the certificate issued by the Board.

Should every State Medical Society be empowered by the Legislature to have an Examining Board armed with similar powers, we should make an important step towards the purification of our ranks.

#### REFORM IN THE MEDICAL SCHOOL OF THE UNIVERSITY OF PENNSYLVANIA.

THE recent changes in the plan of instruction in the University of Pennsylvania are sufficiently radical to invite comment. As will be seen by a notice in our news column, this institution proposes to lengthen its course of instruction, to have a regular gradation of studies, to have professorships which are independent of students, and also preliminary and stated examinations which shall be impartially conducted by a board specially appointed for such purpose. The success of the plan necessarily depends in a great measure upon the ability on the part of the trustees to guarantee a fixed salary for each professor, entirely independent of the number of students in attendance. As the trustees have already settled this matter the success of the undertaking is full of promise. Another example will now be afforded, not only for studying the effects of the endowment plan from a reasonable standpoint, but of becoming practically acquainted with the benefits of preliminary, stated, and independent examinations. We have no doubt that the University has adopted the right course, and its friends should be congratulated on account of its ability to make all its promises good.

### Correspondence.

#### ANTIQUITY OF TARSO-METATARSAL AMPUTATION.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—I send you a record of early American surgery which may interest your readers. It is an extract from the "History of Carolina, London, 1809, by John Lawson, Surveyor-Gen. of No. Ca.," who was finally murdered by the Tuscaroras living in that State.

When journeying through South-western North Carolina to the Appomattox, Va., and was at the Upper Keyawee town on the Yadkin, he writes in his journal, page 53, Feb. 5, 1701: "The Indian that put us in our path had been a prisoner amongst the Sinnenagers (Senecas), but had outrun them, although they had cut his toes and half his feet away, which is a practice common with them (p. 198.) when they take a slave and intend to keep him to work in their fields. They first raise the skin, then cut away half, and so wrap the skin over the stump and make a present cure of the wounds. This commonly disables them from making their escape—they being not so good travellers as before, and the impression of their half-

feet making it easy to trace them. However, this fellow was got clear of them, but had little heart to go far from home and carry'd always a case of pistols in his girdle, besides a cutlass and a fuzee."

Malgaigne, in his "Operative Surgery," 1842, p. 254, writes of the "*Amputation of the entire metatarsus*" "proposed in 1820—performed by Percy, 1789—improved by Hey, 1797, and by Villerme; and lastly by Lisfranc, whose proceeding is almost the only one now used."

A medical friend thinks this Indian practice of 1700 may have become known to the surgeons of the time, and may have attracted attention, and may be another but forgotten instance of the borrowing by the European surgeons of ideas from the New World without giving due credit. It is obviously the earliest record of this operation.

That such a device should have originated with and been successfully practised by our aboriginal savages is quite wonderful.

O. P. HUBBARD.

NEW YORK, May 8, 1877.

## MEDICAL ADVERTISING.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—A young man called to see me recently, and informed me that his business was to print bills or hotels, such as are posted on the doors of the rooms, and that furnish information for the benefit of the guests. He solicited me, on the recommendation of a well-known hotel proprietor, to give him my professional card that he might append it to certain bills that he was preparing. I refused for the alleged reason that it is a method of public advertising, and a violation of the code of ethics. To refute this he showed me several bills that he carried as specimens, such as are displayed at well-frequented hotels in New York and elsewhere, that contained the names of certain eminent physicians. Is not this at variance with the letter and spirit of the code of medical ethics? Does it not seem paradoxical for professors in colleges to descant eloquently on the dignity of the profession, and the observances of ethics, when they resort to public "advertisements," or "handbills," or to other similar acts that are the ordinary practices of empirics? There are others than myself that would like to be at right in this matter, and you will oblige a number of your readers if you will give the subject your intelligent consideration in the columns of the RECORD.

Very respectfully yours,

W. W. HEWLETT, M.D.

BABYLON, L. I., April 30, 1877.

The above is a clear violation of the Code.—Ed.

## PHOSPHORUS ASSIMILATION.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—In your issue April 7th ult., Dr. Samuel Percy makes allusion to my paper published in your journal January 27th last. He states that the conclusion I arrive at, that "phosphorus must be given with (or after) food, as otherwise it is found to attack mucous surfaces," is not in accordance with numerous experiments he has performed. Whether it is in accord with the Doctor's experiments or not, it is certainly in accord with the *practice* of nearly every medical man who uses free phosphorus, its exhibition after meals being rendered necessary by the disastrous irritant effects following its use upon an empty stom-

ach. This is a matter so generally conceded by physicians as the result of their experience, that I am surprised that the Doctor should dispute it. I think physicians who are in the habit of prescribing phosphorus will acknowledge that they have found it necessary to administer it after meals, to prevent undue irritant action.

Dr. Percy denies that the irritant action of phosphorus is due to its oxidation.

Phosphorus exposed to air takes fire. Why?

Nobody disputes that it is because of its rapid absorption of oxygen.

Held in the hand it burns the skin. Why?

Undoubtedly by taking its oxygen from the cuticle, thus disintegrating and destroying it. If it will burn the hand it will also burn the delicate mucous surface of the stomach, if in contact with it.

Upon what other hypothesis will the Doctor explain the occurrence of dyspepsia and gastric irritability following its use? Dr. Percy is led to the belief that phosphorus is absorbed in its pure state. This may be the case, though I find it very difficult to understand how it is possible, as I know of no solvent for phosphorus in the stomach. Administered in solution, it must be almost immediately precipitated upon reaching the stomach. The natural stomach juices are not solvents for it, and unless in solution it cannot be absorbed until after digestion, which would involve oxidation.

Dr. Percy states himself that when "phosphorus has combined with one atom of oxygen, it is no longer irritant." I made this remark in my previous paper, when I also assumed that the phosphorous oxide thus formed united with bases found in the stomach, and being soluble were in this state absorbed.

I have not yet had an opportunity to consult the authorities to whom Dr. Percy refers me, regarding the "improved method of analysis" by which hypophosphites have been, as alleged, found in vegetable tissue.

Dr. Percy next indorses and quotes from my paper: "All 'phosphoid' compounds become converted into phosphate, in which condition they are eliminated," and then he adds, which language and thought are not mine, "and must again go through organization or vitalizing in plant life before again adapted to nourish and support animals." I do not consider *phosphates* suited to the purpose of supplying the system with phosphorus, but I deny that the phosphate derived from vegetable sources in any way differs from the same phosphate obtained elsewhere. If anything can be called infallible in this world, it is most certainly the law which governs chemical combination. Certain elements united in certain proportion produce certain compounds, which compounds, wherever found, have the same composition.

As to Dr. Percy's theory about vitalization, I do not agree with him. It seems to me like wandering from the logical consideration of chemical, as applied to physiological action, into the realms of metaphysics.

Admitting that hypophosphites or allied substances may exist in vegetable germs, etc., I cannot see why they should be superior, *when isolated*, to the same substances artificially prepared. Vitality exists only in certain organized structures, and where these structures are destroyed the "*vitality*" is also. We can no more take this vitality and combine it with other ingredients, bottle it up, for the benefit of suffering humanity, than we can breathe life into the dead.

I have never seen the hypophosphites change into phosphate when in solution in syrup, and I have prepared thousands of pounds. The syrup of hypophos-

phate of lime, if neutral, would instantly show conversion into phosphate by being thrown out of solution, an acid vehicle being essential for its solution. The physicians and pharmacists of New York have had ample opportunity to judge of these syrups, they having been very largely used here for over a year, being now obtainable and regularly kept by nearly every pharmacist of this city. If the syrup of hypophosphite of lime is not converted into phosphate by standing or age, neither are the corresponding syrups of soda, iron, or potassa. Syrups prepared from the ordinary *commercial hypophosphites do precipitate*, but the precipitate is not phosphate—it is carbonate, into which the hydrate, an impurity I have never found absent in commercial specimens of hypophosphites, is converted by absorption of carbonic acid.

The very desirable results attained by Dr. Churchill, which had been nowhere equalled, were obtained by the use of pure and neutral hypophosphites. So much stress does the Doctor lay upon this, that he directs the salts to be given separately or alternately, from the fear that one salt might interfere with or modify the action of another. The use of the syrups prepared by me in strict conformity with Churchill's views has been followed by like results in this city and vicinity, physicians frequently remarking that they have never before seen such prompt action from these salts.

The glaring error of the present time is the complex character of our remedies, and although combinations are frequently required, they should only be made after a thorough study of the peculiar therapeutic action of each, and instances where half a dozen different remedies can be advantageously combined are very rare indeed. This is one objection I make to Dr. Percy's complex formula.

Respectfully yours,

ROBERT W. GARDNER.

BLOOMFIELD, N. J.

### CROTON CHLORAL IN DENTISTRY.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—The specific effect of croton chloral hydrate upon the *fifth* pair in neuralgia suggested its use as an internal and local anæsthetic in toothache. I have derived prompt relief from its use in 5–10 grain doses in the toothache of dyspepsia and pregnancy, and in those aggravating cases which occur in rheumatic and neuralgic patients. Failing to relieve by the ordinary remedies a severe attack of toothache, due to dental caries, I found that a mixture of equal parts of crystallized carbolic acid, croton chloral hydrate and solid Japanese oil of peppermint, promptly removed the pain and obtunded all sensitiveness during the process of filling. I suggested the use of this compound to my dentist, who assures me that he has found it to be the best "obtunder" he has used for deadening the pain of sensitive dentine, and for removing soreness of the gums, which sometimes results from filing and other operations upon the teeth. In toothache, after the mouth has been washed out with a solution of bicarbonate of soda in warm water, and the cavity of the tooth dried with a pledget of cotton-wool, a small piece of the latter should be soaked in the above mixture—gently pressed to remove excess of moisture—introduced into the cavity, and covered with a small piece of dry cotton-wool; or the latter may be first dipped into styptic-colloid or collodion, and then lightly pressed home. In filling teeth, when it is not necessary nor expedient to destroy the pulp by arsenic or other escharotic, nearly

all sensitiveness may be allayed, during the preparation of the cavity, by the following plan: Arm a fine brooch with a small ball of cotton-wool, dip it into the mixture (removing any superfluous material by a little pressure), introduce it into the dental cavity, and retain in position by the introduction of a second piece of wool. In the course of five or ten minutes the cotton-wool may be removed, and the excavation of the cavity may be proceeded with until it again becomes sensitive, when the application should be renewed, and repeated as often as it may be necessary until the cavity is ready for the plug; a result which may be accomplished with little or no pain, and without injury or destruction of the nerve.

C. J. CLEBORNE, M.D.

NAVAL HOSPITAL, PORTSMOUTH, N. H.

### THE PHARMACOPEIA AND THE DISPENSATORY.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—The causes which have led Dr. Squibb\* to broach the subject of a change which, if rendered operative, would involve some radical departures from the methods heretofore pursued in the production of the Pharmacopœia, are briefly as follows: the absence of a number of the hardest and most conscientious workers, by reasons of death and the infirmities of age, from the "Committee of Revision," who have in the past carried the work forward with such signal ability, and, particularly, the non-availability of Drs. Geo. B. Wood and Franklin Bache—those two great master-minds who have for nearly half a century held the widely diversified elements of American medicine in a compact whole—for further work in this direction; furthermore, the too infrequent editions of the Pharmacopœia, and the irregular issues of its elaborate commentary, the U. S. Dispensatory, having culminated, as may have been expected, in the failure of the latest editions of these two works to properly correspond with each other, the Pharmacopœia is "left to stand alone, and with the influence of the Dispensatory not for, but against it." The inherent and fully-recognized defects—that is, fully recognized by those "whose personal interests would not be impaired by the proposed change"—of the present system, not being proof against the repetition of this latter objectionable feature (not to mention others), the value of one or the other, or both, of these works is weakened, as they are expected and understood to be in perfect accord with, and to supplement each other. "At the time of the last revision (of the Pharmacopœia) Dr. Bache was dead, and Dr. Wood so infirm in health that his services were not useful, but were rather obstructive in the committee, and have continued to be so unserviceable to the Pharmacopœia interests, that now, while his Dispensatory still overshadows the Pharmacopœia, it does not embrace it, and has not been revised to meet the wants of the present plan of revision; whilst by allowing his publishers to change the date on the title-page of the Dispensatory, it appears to post-date the last revision of the Pharmacopœia, which it does not contain or comment upon, while it still, in a large measure, takes its place," and "the thirteenth edition of the Dispensatory remains year after year unrevised, until it has become simply a book of reference for the past, and a blind to those who go to it for the progress of modern knowledge." Some systematic arrangement must clearly be adopted

\* The American Medical Association and the Pharmacopœia of the United States of America, by E. R. Squibb, M.D., Brooklyn, N. Y.

in the near future, which will keep the works (if both be continued in their present relations) abreast of each other, or else institute, as Dr. Squibb proposes, a plan which will in effect destroy the peculiar monopoly which the Dispensatory has enjoyed, by constructing a Pharmacopœia of so enlarged a scope that the Dispensatory will be superfluous. Some such course is rendered imperative if the Pharmacopœia is to command any general acceptance, or to be in deed and in fact the "national standard."

The U. S. Pharmacopœia, as is well known, is and has been since 1820 in charge of the "National Convention for Revising the Pharmacopœia," a body being nominally composed of delegates from the several State Medical Societies and Medical Colleges of the country, and also from pharmaceutical institutions, but in reality representing but a small minority of these organizations, and consequently but a small minority of the profession, as the calls issued for the decennial meetings of this convention have never been responded to in representative numbers. This National Convention, having decided upon all the general principles of the Pharmacopœia, and ordered its general scope, and plan, and methods, it appoints a "Committee of Final Revision and Publication" to carry out these general principles and plan in the details of the revision, and gives this committee entire charge of the Pharmacopœia until the next decennial period.

The work thus appearing but once every ten years, a period intervenes between each edition which is long, and has been for several decades, notoriously too long, as these infrequent issues cannot do justice to be important and progressive interest involved. After the second revision of the Pharmacopœia, two members of the Committee of Revision—Drs. Wood and Bache—perceiving that an explanatory commentary upon the Pharmacopœia, which would include materia medica and pharmacy, and be more frequently issued, would be of advantage to the profession, established that grand monument of medical and pharmaceutical lore, the U. S. Dispensatory, which has probably been the most successful medical book of the age, in its circulation and influence far surpassing the Pharmacopœia. As a former writer remarks:

"In order to insure the permanence and authority of the U. S. Pharmacopœia, and with no idea of the pecuniary success which it has achieved, the U. S. Dispensatory was published by its authors, and American pharmacy, to the astonishment of many, leaped at once, as it were, into the arena fully armed, and prepared to maintain the foremost rank, which it has ever since held." The Dispensatory now, however, being deprived of the services of its able authors, and he fears being well grounded that it will degenerate into a mere commercial enterprise, its managers or editors caring more for the "clinking of the guinea" than for its value scientifically (if it is turned over to be "hair-apparent," a verbose and mediocre scissors-and-paste compilation may confidently be expected). The profession must look in another direction for a representative Dispensatory, or take the proper steps to render the present one such.

The Pharmacopœia, which is supposed to be the national standard, being superseded by, and subordinated to, the private book of two members of the committee of Revision, and the last (thirteenth) edition of the Dispensatory not being in accord with the Pharmacopœia of 1873, hence not being a commentary upon it, the questions arise, How can a Pharmacopœia be obtained that shall be a national standard in fact; that shall be issued with sufficient

frequency to keep the profession *au courant* with therapeutic progress? that shall not conflict with the Dispensatory; and, further, by whom should the work be issued?

Since the organization of the American Medical Association the profession of this country has been largely, if not fully, represented at its sessions, which are held annually. This extensive organization embraces and practically absorbs that portion of the profession which is represented in the National Convention for Revising the Pharmacopœia, and, as the greater includes the less, the American Medical Association, in virtue of the fact that it, alone, is truly representative, should certainly be the body empowered to issue the Pharmacopœia, which is one of the most important of the general interests of the Association.

The gist of Dr. Squibb's proposition is that the American Medical Association, the only organization which represents the whole profession of the nation, assume charge of the Pharmacopœia, control and issue it, and that the present National Convention for Revising the Pharmacopœia be abolished and superseded by a sub-organization or committee, to be called "The Pharmacopœial Council of the American Medical Association," which council is to take charge of the revision and publication of the Pharmacopœia; that the Dispensatory be ignored, but the Pharmacopœia be so augmented as to be a substitute for the Pharmacopœia and Dispensatory both; in other words, that the work thus issued be a combined Pharmacopœia and Dispensatory.

Just here the difficulty will hinge, no doubt, and the matter be discussed *pro* and *con* with much warmth by the respective partisans, who will marshal their forces in battle array at this juncture. The champions of the present system (is it a system?) may argue, quite plausibly, that the Pharmacopœia and the Dispensatory, mutually dependent upon each other, yet each filling its own proper field, have travelled along together for so many years, and have met the wants and requirements of two or three generations of physicians and pharmacists in such an acceptable manner, that they will be loth to have a system that has stood the test of long and successful experience substituted by one that is admittedly experimental; and that the conjoined work, representing Pharmacopœia and Dispensatory, would be too voluminous and minute on many points for a Pharmacopœia, and, at the same time, too condensed and restricted in its scope for a Dispensatory.

To obviate these and similar objections, which will be urged in an exaggerated manner, therefore, instead of instituting, at this time, such an abrupt and sweeping change as Dr. Squibb's plan, in its entirety, would necessitate, a modification of the plan, which would not ignore a Dispensatory, would, it is believed, remedy the evils complained of in an equally satisfactory manner, and secure, through the value of the work (Dispensatory) commercially, the additional advantage of enabling the Association to adequately pay for the labors of the council in revising and publishing, which labor has heretofore been done gratuitously; for if a consolidated Pharmacopœia and Dispensatory, as proposed, be issued by the Association, and the Dispensatory of Wood and Bache be still continued and maintain its established wide circulation (it does not appear likely to be withdrawn), the chief evil would not be remedied, as a really national standard would be as far off as ever, the Association's work being, to a large extent, unable to displace the work of Wood and Bache.

That the American Medical Association is the proper

custodian of the Pharmacopœia of the United States can hardly be denied; that this representative body is, also, the proper custodian of a Dispensary of the United States, is, we take it, equally undeniable. At the present time the United States is provided with a Dispensary of great excellence and of universal reference, a work lacking but one essential qualification—that of being the authorized utterance of the American profession through the American Medical Association. This latter may be said with regard to the Pharmacopœia. Now, we think an arrangement should be consummated, if it can be done advantageously, by which the ownership and management of the present Dispensary, as well as of the Pharmacopœia, would become vested in the American Medical Association; if the overtures in this direction meet not with success, then, a new Dispensary to be constructed forthwith. The attempt of Dr. Wood to create the impression that it would be a well-nigh impossible task to establish a new Dispensary "having any chance to displace the old," is simply buncombe. By the way, Professors Stillé and Maisch have in preparation, and will shortly issue, a new Dispensary, to be styled "The National Dispensary," which, judging from the distinguished abilities of these gentlemen, will be a formidable rival to the present one, and will further serve to illustrate Dr. Squibb's argument for the necessity of centralization into one national standard. There is nothing but the mutual submissiveness of the profession in reference to some artificial and arbitrary "standard," to prevent a host of good, bad, and indifferent Pharmacopœias and Dispensaries from clamoring for their patronage, each one, of course, claiming to be the representative work.

The modification that may be suggested is, that the American Medical Association assume control of both the Pharmacopœia and the Dispensary, and that both works be placed in charge of one and the same sub-organization, or council, or committee of the Association, said council to see to it that they are issued regularly and *simultaneously*, at more frequent intervals than formerly—say every five years. By this arrangement a degree of uniformity would be attained, which has, in the past, been entirely lacking, and which would remove, in great part, the causes for the unfavorable criticisms to which the works have been subjected.

In regard to the committee or council of revision and publication, care should be taken that the mistake be not made of having this committee too small, as this fault would possibly be taken advantage of by some one or two members in monopolizing the time in ventilating and urging their own peculiar crotchets, to the exclusion of better material. The council should be sufficiently and prudently large, and should be selected with the most extreme care and caution. Only men of acknowledged ability in this field of labor, and whose right to do this kind of work is unquestioned, would be available. A council which should contain such representative workers as Drs. Edward R. Squibb, William A. Hammond, Edward H. Clarke, N. S. Davis, Alfred Stillé, John B. Biddle, H. C. Wood, H. I. Bowditch, among its members, would, in its very composition, be an assurance that the requisite duties would be thoroughly and properly performed.

With the exception of the points herein noted, or rather, with the modifications herein noted, which are considered judicious by others beside the writer, the plan devised by Dr. Squibb is, without doubt, a close approximation to the end desired. Having been for

many years an enthusiastic and thorough worker in this department, Dr. Squibb is specially qualified to institute any desired improvements in this direction, and his suggestions will carry great weight with them. As the subject is the special order of business for ten o'clock of the second day of the approaching meeting of the American Medical Association, it should, in the meantime, be carefully thought over, particularly by those members of the section in which the matter will be brought up for action.

In the numbers of the *Philadelphia Medical Times* for Nov. 15, 1870, and Jan. 2, 1871, the subject of the present status and future prospects of the Pharmacopœia is ably set forth, editorially. This writer is of opinion that the Pharmacopœia should be governmental in its origin, and says: "We think the time has nearly, if not fully, come when Congress should be asked to give legal authority to our national standard. Such law need not encroach or in any way interfere with the commercial rights of any. It would be sufficient, we think, for it to consist of two parts: the one giving legal sanction to the revisory convention and its committees as at present appointed and governed; the other requiring of pharmacutists that when any preparation be called for under the official name, it should be prepared in accordance with the official standard. There is such reasonableness in this that we think Congress would readily pass a moderate law, were it memorialized by the various medical societies and colleges throughout the land;" and, in closing, says: "To call attention to this matter, to excite, if possible, discussion in the medical journals, so that at last action may be taken by some body or bodies, is the object of the present editorial. If it fail in doing so, it will be but bread cast upon the waters; and, although neither a prophet nor the son of a prophet, we fear lest the day may come when, by very confusion and vexation, the profession will be forced to look into the subject seriously, and to attempt a reformation, now easy, but which then will be a veritable cleansing of Augean stables."

The subject is one that merits careful study, and physicians should be urged to agitate the matter from their various standpoints, through the medical journals. By thus being advised of the views of the profession at large concerning it, the section would be likely to arrive at a satisfactory solution of the problem, at the meeting in Chicago.

WILLIAM N. BAYNTON, M.D.

COLUMBIA, PENN., May, 1877.

## ARMY NEWS.

*Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from May 6 to May 12, 1877.*

EDWARDS, L. A., Surgeon. Leave of absence on surgeon's certificate of disability further extended six months. S. O. 101, A. G. O., May 10, 1877.

DE WITT, C., Asst. Surgeon. Granted leave of absence for one month and twelve days. S. O. 98, A. G. O., May 7, 1877.

KING, WM. H., Asst. Surgeon. Assigned to duty a Cheyenne Agency, D. T. S. O. 55, Dept. of Dakota May 3, 1877.

ANDREWS, W. C. C., Asst. Surgeon. Drowned near Fort Stevens, Oregon, April 19, 1877.

**DR. H. H. GREGORY.**—IN MEMORIAM.—At a regular meeting of the Harlem Medical Association, held at their rooms on the 10th inst., the following preamble and resolutions were unanimously adopted:

*Whereas*, It has pleased an all-wise Providence to remove from the sphere of his usefulness our well-beloved associate, Dr. Harvey H. Gregory, and whereas, while we bow in humble submission to the Divine decree, we desire the unavailing consolation of a tribute to his memory, therefore be it

*Resolved*, That in our deceased coworker we have always found a zealous promoter of the best interests of our profession, a judicious counsellor, an enthusiastic friend, and consistent advocate of harmony in our midst.

*Resolved*, That to Dr. Gregory this Association owes its organization, and much of its usefulness; that it has profited by his practical suggestions and honest endeavors to stimulate the zeal of its members.

*Resolved*, That the medical profession, especially of this locality, remember with pride his magnanimous record, his cheerful self-sacrifice, his unswerving integrity, and his broad humanity.

*Resolved*, That with unfeigned sympathy for the bereavement of that family circle, around which his best affections clustered, we offer this simple memorial, and with it the assurance that though he fell at his post with scarcely a warning, and in the prime of his manhood, his career was not without honor, nor his mission without fruit.

*Resolved*, That a copy of these resolutions be presented to the family of our deceased associate, and be also published in the medical journals of this city.

JOHN SHRADY, M.D.,

JOHN B. CAMPBELL, M.D.,

HENRY T. PEIRCE, M.D.,

Committee.

—At a meeting of the Yorkville Medical Association, held May 8, 1877, the following preamble and resolutions were adopted:

Inasmuch as death has suddenly removed from our midst our highly esteemed and much beloved brother, H. H. Gregory, M.D., while in the prime of life, apparently in the vigor of perfect health, in the crowning success of his cherished profession, in the unfeigned love of a large and rapidly increasing circle of friends, in the exalted appreciation of his patients, and in the unsullied respect and confidence of his church, therefore be it

*Resolved*, That we have lost one whose presence in memory we shall ever be proud to recall as an active and zealous member of this Association, and an honor

to its medical status, and an example to its associates of pure friendship, noble generosity, and true manliness.

*Resolved*, That the medical profession at large have sustained in his death the loss of one whose qualities may be feebly grouped as the working, sympathizing, skilful, and gentlemanly physician.

*Resolved*, That the community in which he immediately moved have reason to bow in humble sorrow at the loss of a noble and exemplary citizen, a faithful friend, a respected physician, an ornament to the church, and a fit example of morality.

*Resolved*, That we deeply sympathize with the grief-stricken family of our deceased friend, and assure them of the sincere fellow-feeling of all who knew of their great affliction.

*Resolved*, That in his sudden and unexpected death we deeply realize the shortness and uncertainty of life, and would learn afresh the lesson that we, like him, should so live that we may not be afraid to die.

*Resolved*, That a copy of these resolutions be sent to the family of the deceased and also to the medical periodicals of this city for publication.

W. H. STUDLEY, M.D.,

J. R. MACGREGOR, M.D.,

F. A. THOMAS, M.D.,

Committee.

**METRIC SYSTEM.**—The *Boston Congregationalist* opposes the adoption of the metric system, because it does not want to have the revised version of the New Testament to read: "Neither do men light a candle and put it under a *hectoliter*."

"**OPIMUM ANTIDOTES.**"—Dr. J. B. Mattison, of Brooklyn, writes: "Your item in last week's issue, relative to 'opium antidotes,' prompts me to say that the analysis of the Collins nostrum revealed, per hundred parts, glycerine 66.89, water 28.66, morphia 4.45, the proportion of morphia amounting to 25½ *grs. per ounce* of the mixture, of which a teaspoonful was to be taken four times daily. The specimen was furnished me by a gentleman—an author—addicted to morphia, who had expended hundreds of dollars and months of time in a fruitless effort at cure.

"The Drollinger compound is essentially the same, for reasons at once appreciable, and all the other reputed 'antidotes' contain opium in more or less abundance, despite the false assertions of their makers to the contrary.

"An eminent gentleman, who has had the most extensive professional experience on record among inebriates, writes: 'I must thank you for the exposé of this opium cure *swindle*, for such I know it to be. You have done the cause of true reform a noble service.'

**REFORM IN THE MEDICAL SCHOOL OF THE UNIVERSITY OF PENNSYLVANIA.**—At the recent meetings of the trustees of the University, the following important changes have been instituted in the course and curriculum of the Medical School.

The European system has been adopted *in toto*. The course has been lengthened, attendance being required of the student upon three courses of lectures of five months each. There is to be an examination for admission, and examinations at the end of every year (of five months). The order of studies is to be graded. The first year devoted to botany and chemistry, and work in the chemical laboratory. Anatomy, physiology, and materia medica are to fill the second

year. The third year is to be entirely given up to therapeutics, physical diagnosis, surgery and obstetrics. The classes are to be reduced in size; the number of men in a class not to exceed sixty. A fixed salary of \$3,000 is to be paid each of the professors by the board of trustees. The determination is to offer the most complete course of medical instruction with the smallest increase in the cost of fees. Though the endowment of the medical chairs is looked forward to by the trustees as a matter of the very near future, it will not have any effect upon the regular payment of fees. The fees in future are to be paid to the treasurer of the board of trustees, and not to the professors. The examinations at the end of each year and those for a degree are to be passed before a board of seven, appointed from the whole faculty, and not by separate professors, as hitherto. The good work in the way of private instruction hitherto done by the "Quiz" Associations will not be interfered with by the new order of things. All students who desire their additional aid will have the same facilities as heretofore. The matriculates of the years of 1875 and 1876 will not be affected by the new order of things, unless at their expressed desire.

The money already subscribed towards a full endowment fund is considerable enough to encourage the trustees in their efforts towards reform, and is continually increasing. The clinical professors are in future to rank with the regular medical faculty. They are Prof. Wm. Pepper, of Clinical Medicine; Prof. James Tyson, of Histology and Morbid Anatomy; Prof. Wm. Goodell, of Diseases of Women and Children and Clinical Obstetrics, and Prof. ———, of Clinical Surgery. The winter term of lectures is to extend over the months of October, November, December, January, and February, as hitherto. The spring course begins on March 20th, and lasts till the middle of June. It includes lectures by the old auxiliary faculty on botany, zoology, geology, hygiene, and medical jurisprudence, delivered during the afternoons. The new faculty appointed to lecture during the mornings of the spring course comprises Drs. Lenox Hodge, on Regional Anatomy; Henry Chapman, on Experimental Physiology; Roland Curtin, on Physical Diagnosis; Louis Starr, on Pharmacy; Henry Simms, on Histology; Elliot Richardson, on Practical Obstetrics; Charles Hunter, on Minor Surgery; Daniel Bray, on Operative Obstetrics; DeForest Willard, on Orthopaedic Surgery; Charles Risley, on Ophthalmoscopy; J. Wm. White, on Venereal Diseases; Guitéras, on Symptomatology; C. K. Mills, on Electrical Therapeutics; and Shakespeare, on the Eye. The regular matriculates attend this course upon the payment of a matriculation fee of \$5; others upon the payment of \$30 for the course ticket.

The immediate effect of these so radical changes will be to *reduce the size of the classes* at the University Medical School, but to *raise the average standard of ability and greatly enhance the value of the diploma*.

The late resignations of Dr. Robert Rogers from the Chair of Chemistry at the University (he has since accepted the Chair of Chemistry at the Jefferson Medical School, made vacant by the resignation of Prof. B. Howard Rand), of Prof. F. Gurney Smith from that of Physiology, and of Prof. John Neil from the Chair of Clinical Surgery, have no connection with the changes instituted, but were the results of other definite causes.

The places made vacant by these resignations are to be filled at an early date. Among the applicants for the Chair of Chemistry are Profs. John Reese and George Barker, of the University, and Prof. Wormley,

of Ohio. Drs. Lautenbach and Dépuis, the former of Schiff's Laboratory, at Geneva, and the latter an assistant of Brown-Séguard, at Paris, together with Drs. Henry Chapman and George Morehouse, both of this city, have applied for the Chair of Physiology. The trustees intend that the successful candidate for this position shall devote his whole time to the investigation and study of physiological questions, with instruction thereupon.

The nominees for the Chair of Clinical Surgery are Drs. Chas. Hunter, Harrison Allen, T. G. Morton, Lenox Hodge, John Ashurst, and John Packard.

Dr. J. J. Richardson is delivering lectures upon hygiene in the auxiliary faculty, in the place of Dr. Horace Hare, disabled by serious sickness, and Dr. J. H. Rothrock has been appointed to the Chair of Botany, in the place of Dr. H. C. Wood, resigned.

COMPARATIVE PROTECTION OF VACCINATION AND VARIOLA.—Dr. L. P. Fitch, of Charles City, Iowa, writes: "Prof. Alonzo Clark once stated to the class, if I remember rightly, that a successful vaccination is a better protection against small-pox than the having had small-pox. Still it is the opinion commonly held by the laity, at least, that once having had small-pox is complete protection against a subsequent attack. And if a case of variolous disease occurs in a community it is thought to be very desirable to procure a nurse who has had small-pox.

"I do not find that the books, directly at least, advise the vaccination of those who have had the variolous disease. A case in point has just come under my observation. An Irishman, about forty-five years of age, when about five years old, was inoculated with variolous matter, and the pocks on his face are witnesses that he had quite a severe form of small-pox. On the 9th October last he brought his little daughter to me to be vaccinated, and after a little urging the father was vaccinated as well. The virus used was from a child I vaccinated a short time before with animal virus. Twelve days later father and child came back, according to promise, to 'show their arms.' The three vesicles or pocks on the father were fully as large and well developed as those on the child, and hers were perfect. Those on the father were more advanced than those on the child, being dried in the centre."

STIMULANTS USED BY THE RACE.—It is estimated that coffee, both beans and leaves, are drunk by sixty millions of the human family. Tea of all kinds is used by five hundred millions, and opium by four hundred millions; alcohol, in its various forms, by five hundred millions of the human race. Tobacco is probably used by seven or eight hundred millions. These startling facts indicate a large proportion of the race using some substances that are either stimulants or narcotics. The work of the physiologist, in the future, will be to determine the true place in nature of these substances, and indicate where their use ends, and abuse begins.—*Quar. Jour. of Inebriety*.

CONTAGIOUS DISEASES.—The State Board of Health of Wisconsin have issued recently some excellent rules for preventing the spread of scarlet fever and diphtheria. For the most part they are based upon those laid down by the Health Board of this city.

CONNECTICUT MEDICAL SOCIETY.—The eighty-sixth annual convention of the Connecticut State Medical Society will be held in Hartford, Conn., May 23d and will continue in session the following day.

C. W. CHAMBERLAIN, M.D., Secretary.

# THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, May 26, 1877.

## A NEW DISCOVERER OF ANÆSTHESIA.

THERE is another claimant for the honor of discovering anæsthesia. This announcement will hardly startle the professional mind, thoroughly accustomed as it is to listen to the discussions of questions of priority. On the ether discovery it is quite a relief to have our thoughts diverted into an entirely new channel. Indeed, for the very novelty of the idea, we willingly ignore, for the present at least, Wells, Morton, and Jackson, and pay our respects to Dr. C. W. Long, of Athens, Georgia, who, Dr. Sims claims,\* is the real discoverer of anæsthesia. It is such a matter of congratulation to have this vexed question so definitely settled at last, that we half forgive the modesty of Dr. Long for keeping himself so long in the background. At last, however, he is fortunate in having so distinguished a champion as Dr. Sims to urge his claims to the profession and to the world. The narrator became acquainted with the facts of Long's labors by mere accident.

In October, 1876, Dr. P. A. Wilhite, of Anderson, S. C., came to New York to consult Dr. Sims concerning the health of his daughter. Her case required a surgical operation, and it was necessary for her to take ether, which was given by Dr. Harry Sims. After the operation was over, and while they were waiting to see the patient fully restored from the effects of the anæsthetic, the conversation naturally turned upon the wonders of anæsthesia, when Dr. Wilhite said, "Doctor, I assisted at the first operation ever performed under the influence of ether." Dr. S. said, "But how could this be when you have never been in Boston, and the first operation ever performed under ether was by Warren, of Boston, in October, 1846, or, as some claim, by Marcy, of Hartford, in 1846?" Dr. Wilhite then told him that he had assisted

Dr. Crawford W. Long, of Georgia, in extirpating a tumor from the neck of Mr. Venable, in March, 1842, while he was completely anæsthetized by the inhalation of sulphuric ether—that Mr. Venable was as profoundly anæsthetized as the patient then lying before them—and he also said that he had assisted Dr. Long to operate on other patients under the influence of ether in 1843 and 1844, while he was a student of medicine in Dr. Long's office. Dr. W. declared that Long was the real and original discoverer of anæsthesia, and he believed he would be so acknowledged if all the facts in the case were fully set forth.

As an item of corroborative history the patient upon whom the operation was performed, having been sworn July, 1849 (seven years after having taken the ether), says:

"In the early part of the year (1842) the young men of Jefferson and the country adjoining were in the habit of inhaling ether for its exhilarating powers, and I inhaled it myself frequently for that purpose, and was very fond of its use. While attending the Academy, I was frequently in the office of Dr. C. W. Long, and having two tumors on the side and rather back of my neck, I several times spoke to him about the propriety of cutting them out, but postponed the operation from time to time. On one occasion, we had some conversation about the probability that the tumors might be cut out while I was under the influence of sulphuric ether, without my experiencing pain, and he proposed operating on me while under its influence. I agreed to have one tumor cut out, and had the operation performed that evening (afternoon), after school was dismissed. This was in the early part of the spring of 1842. I commenced inhaling the ether before the operation was commenced, and continued it until the operation was over. I did not feel the slightest pain from the operation, and could not believe the tumor was removed until it was shown to me. A month or two after this time, Dr. C. W. Long cut out the other tumor situated on the same side of my neck. In this operation, I did not feel the least pain until the last cut was made, when I felt a little pain. In this operation, I stopped inhaling the ether before the operation was finished. I inhaled the ether in both instances from a towel, which was the common method of taking it."

These, then, are in substance the facts of the case as presented by Dr. Sims. Recollecting that Wells, who is generally believed to be the discoverer of anæsthesia, first used his nitrous oxide in 1844, Long apparently antedates him two years and eight months. Morton's anæsthesia with ether being on the 30th of September, 1846, was antedated four years and six months. So says the new history before us. If it had only been written sooner, how much trouble and printers' ink would have been spared? We are afraid, however, that many will not even take the decision of Dr. Sims as final, and will still continue to be disputatious. But it is proposed to compromise the difficulty by asking Congress to vote to each of the families of Long, Wells, Morton, and Jackson the sum of one hundred thousand dollars. As there is not much likelihood that Congress will be in any hurry to take up the discussion, there may still be time and oppor-

\* Discovery of Anæsthesia, by Dr. J. Marion Sims, *Virginia Med. Monthly*.

tunity for a few discoverers to put in their claims. In the meantime it might be eminently proper for those having charge of the monument in Boston to enlarge its inscription surface, that when the roll of honor is finally complete, and the last man shall be satisfied that justice is done, no invidious distinctions shall be made. Then, and not till then, will each believer be able to worship at the particular shrine of his pet idol.

#### THE MEDICAL PROVIDENT SYSTEM.

THOSE who are hopeful of the establishment of the Medical Provident System in this city, received fresh encouragement from the report of Dr. S. F. Morris at the Public Health Association. It appears from an examination of the financial condition of the different dispensaries that, with one exception, they are all behindhand. So far as the purely selfish interests of these institutions are concerned, there is the strongest incentive for favoring any plan for pecuniary relief. This, after all, is the only hope for the Provident System. If the dispensaries as a whole are willing to adopt such a scheme, the battle is more than half won. We do not see why they should not do this. There is not the slightest danger of denying the poor such medical charity as they may deserve. They have never had reason to complain on account of the lack of gratuitous services. In fact, the error has been upon the other side, and the more we try to correct it the better will it be for the really needy. If the dispensaries are willing to become medical provident concerns, giving professional services only to those known to be poor, and making all others pay for them, we believe a proper initiative will be taken. The experiment deserves a trial, but it can only succeed as the result of a joint action on the part of the respective managers.

In the discussion of the question of the Medical Provident System we confess to a partiality for the interests of the medical profession. In all matters of equal importance to the profession this is at once our pleasure and our duty. But the circumstances connected with this particular project make it more than ordinarily obligatory on our part to lean strongly to the professional side. The physician wants money even more than the poor need advice. We are not injuring the poor so much by throwing our advice away, as we are injuring ourselves. If the Medical Provident System can help us to check the growing abuses of medical charity, then the sooner we adopt it the better. Any plan which proposes to make pecuniarily available to the physician that vast number who go to dispensaries, and yet who can afford to pay something, deserves very careful consideration. We are in favor of small fees rather than none at all. From Dr. Morris's report we learn that the working of the Provident System in England is very satisfactory. As might have been supposed, the greatest care is taken to draw the lines of distinction between the absolute pauper, those who pay a little, and the third class

who can afford to give a legitimate fee. The rules of these British Associations could with profit be adopted by us. What is needed is a concerted action on the part of all our leading charities to give the project a fair start. We are glad to see that proper measures have been taken by the Association to secure this end, not the least beneficial of these being the enlistment of the valuable services of the Society for the Relief of the Poor in perfecting a plan for district inspections. It is useless to appeal to the self-respect of the would-be pauper, for he has none. His reform lies more in the direction of compulsion than persuasion. But even those who are most encouraged by the recent efforts to give it a practical turn have reason to look with very distrustful eyes to the doings of the outdoor department of the New York Hospital, and to the shameful abuses in our college and hospital clinics.

But the best regulated provident concerns can never hope to compete with "the original dollar shop" of large capital and extensive advertising facilities. Medicine is incapable of being elevated into a business and still retain its identity. The best that can be said for the Provident System is that it is not a matter of pecuniary speculation, but one of reform.

#### PROFESSIONAL DUTY AND SACRIFICE OF LIFE.

TWO surgeons died recently in Paris from diphtheria, the result of sucking the windpipes of patients upon whom they had operated for croup. These lamentable accidents are becoming so common that they are beginning to be considered as a natural consequence of the performance of professional duty. There is such a desire on the part of the profession to save life at all hazards, that it appears almost sacrilegious to question the right to indulge in its unlimited gratification. But is it not quite pertinent to inquire if the risk to the life of an operator by sucking a diphtheritic wound is sometimes needlessly incurred? At all events, is there not some means which can be devised to render the hazardous procedure unnecessary? In this day of invention, cannot some efficient instrument be constructed which shall take the place of the surgeon's mouth in cases of like emergency?

#### MEDICAL LIBRARY FOR THE ACADEMY OF MEDICINE.

VIEWED from the proper standpoint, the effort being made to establish a library by the New York Academy of Medicine deserves the most unqualified encouragement. In the first place, the Academy is the only medical home of New Yorkers, and probably will continue to be such for many years to come. It is true there are many public libraries in this city where medical works may be found, notably the Astor, Mercantile, New York Society and College of Pharmacy, but in all of these either a certificate of membership is required, or else a subscription fee.

The late Dr. Valentine Mott, by a provision of his will, directed that his library and surgical instrumen-

should be preserved and placed in a room specially appropriated for that purpose. His wife was empowered to bequeath them to one or more of his grandsons who should bear his name, study medicine, be a graduate, and have a respectable, honorable name. With the addition of that of the late Dr. Isaac Wood, this library forms the Mott Memorial Medical and Surgical Library.

The library of the New York Hospital is the largest, and in some respects, the most complete in the city. It numbers ten thousand volumes, and its yearly increase is over one hundred and twenty-five volumes. Many other libraries or small collections of books exist in connection with hospitals, colleges, etc., or independently, but they are mostly intended for the use of specified persons, and cannot be reached by those outside.

The following points are insisted upon by Dr. S. S. Purple in his address on the Medical Libraries of New York: 1st. The institution of a Library Fund, which should be properly invested in such securities as will be safe and yet yield a fair interest; and 2d. Voluntary donations of medical books, pamphlets, journals, portraits, engravings, busts, and manuscripts, which may have become useless or burdensome to their possessors. He also suggests that the library shall be open to the use of all regular members of the profession. The popular error which exists in the profession that only the best books and latest editions are worth preserving is deprecated, and all physicians of good standing are invited to contribute any book or pamphlet which may appear useless; for, however obscured or darkly concealed by peculiarities of language, there are many facts which will ultimately be unearthed and serve a good purpose.

## Reviews and Notices of Books.

ATLAS OF SKIN DISEASES. By LOUIS A. DUHRING. Philadelphia: J. B. Lippincott & Co. 1877.

AFTER a delay, which was unavoidable, the second part of this admirable atlas has appeared, and the publishers assure us that hereafter the parts will be issued regularly. There are in the second four illustrations as in the first, which are of a very high order of merit. Under the first picture we find the title *acne rosacea*, at which we are somewhat surprised, as it strikes us as a most excellent reproduction of a case of *acne vulgaris*, in which pustules are the preponderating lesion, between which are erythematous patches. The presence of well-marked numerous comedones strengthens this opinion in our minds. As a work of art the picture is very good, both as to the delineation of the lesions and of the shading of the colors. The second picture of *ichthyosis* is also admirable, the diamond-shaped plates of epidermis, spoken of by some authors, being very naturally portrayed. The artist has been, we think, particularly happy in reproducing the *café au lait* color of *tinea versicolor*, of which we have a typical example. Perhaps the best illustration in this fasciculus is that showing *syco-*

*non-parasitica*, both as to the prominent manner in which the lesions are delineated, and the grouping of the colors. The explanatory text is clear, simple, and practical, and will aid the student in this department greatly. We accord to this second as to the first part our unreserved praise and give it our hearty commendation as an atlas of skin diseases which is both practical, simple, and accurate; certainly the art of reproduction of morbid states of the skin has been brought to a high state in this work by Dr. Duhring, of whom it may be truly said that he adorns that which he touches.

## Reports of Hospitals.

### MANHATTAN EYE AND EAR HOSPITAL. CASES ILLUSTRATING ELECTRO-THERAPEUTICS.

SERVICE OF DR. E. C. SEGUIN.

W. R. BIRDSALL, M.D., CLINICAL ASSISTANT.

CASE I.—*Incontinence of Urine*.—Male, *æt.* 9; was presented at the clinic July 1, 1876. He had an attack of pneumonia when two years of age, and during convalescence incontinence of urine came on, from which he did not recover. During all this time the incontinence was about the same, night and day. The urine was evacuated in considerable quantities at intervals of about three hours, he being perfectly indifferent to its escape.

The electrical treatment consisted in the application of the faradic current three times a week. Large sponge electrodes were used, one placed over the sacrum, the other on the pubis. The fortieth of a grain of strychnia was given twice a day.

July 10.—No improvement. The strychnia is increased to the thirtieth of a grain.

July 12.—No change until to-day. He is now able to urinate voluntarily with considerable force. The strychnia is increased to the twentieth of a grain.

July 17.—He has passed urine quite often since he was last here. He was ordered to urinate every hour. The strychnia is discontinued, and a fifth of a grain of extractum belladonnae and fifteen minims of extractum ergote fluidum are to be given three times a day.

July 19.—There has been no incontinence for two days, except at night. He is directed to increase his doses one-third.

July 28.—No diurnal incontinence has existed for ten days, but there is incontinence during sleep. As no effect has been observed from the belladonna, the doses are to be increased to one-third of a grain.

The patient failed to come to the clinic after his visit on July 28, and later, unfortunately, could not be found. It is probable that putting the boy thoroughly under the influence of the belladonna would have finished the cure.

CASE II.—*Paralysis of Left External Rectus*.—Female, *æt.* 29, came to the Manhattan Eye and Ear Hospital, Aug. 14, 1876, complaining of diplopia. One week previous she was in good health. She went out of the house into the hot sun for a few minutes, and on returning felt giddy and sick. Within three hours she noticed diplopia and dimness of vision. There was no other disturbance, except a slight headache immediately following the exposure, and a severe one on the third day.

Examination showed paresis of the left external rectus; the insufficiency for distance being 21°.

The patient was transferred by Dr. Webster to the class for nervous diseases.

Electricity was ordered. Galvanism was applied continuously for about two minutes, with anode on the temple, and cathode, a large sponge electrode, over closed eye. Faradization was accomplished by the use of an electrode, consisting of an ordinary wooden electrode handle, in one end of which was screwed a short brass rod about an inch and a quarter in length, that terminated in a rounded head an eighth of an inch in diameter. This was used by carefully placing it on the conjunctiva, over the insertion of the paralyzed muscle, and allowing the sensitive surface to become accustomed to its presence before the circuit was closed. Then an assistant was directed to close the circuit by placing a sponge electrode on the temple, the operator keeping the lids apart, and holding the small electrode on the conjunctiva in a firm but gentle manner. By this method the conjunctiva may be educated to tolerate both the mechanical and electrical irritants for a few seconds, which it would not do if both were applied at once. A very weak current was used, and as the electrode must be removed every few seconds, it was necessary to apply it from five to ten times at each *séance*.

Aug. 25.—Ordered R Extr. nucis vom. gr. iii.; ferri redact. gr. xxx. M. et ft. pil. No. xii. Sig. One after each meal.

The patient received electrical treatment twice a week, and continued to improve until Nov. 8th, when there was an insufficiency of only 1°.

CASE III.—*Compression of Musculo-Spiral Nerve*.—Male, *æt.* 58. Two weeks before his appearance at the clinic, Oct. 7, 1876, he went to bed inebriated, and awoke with numbness and loss of power in the right hand and wrist, on which he had l<sup>am</sup>.

He exhibited a complete paralysis of all the extensors of the wrist and fingers, and the supinator longus on the right side. There was galvanic reaction to six cells in the extensors on the right side, but the same current produced none on the left, and a faradic current of moderate strength caused better reaction on the paralyzed than on the healthy side.

Faradism was ordered; also a support to the hand and wrist by an elastic band attached at the arm and fingers, in accordance with the indication of Dr. John Van Bibber, of Baltimore.

Oct. 23.—There is good contractility of the extensors to the faradic current, but only slight voluntary power in the fingers.

Nov. 3.—The patient is somewhat inebriated. There is complete analgesia in both arms, no pain being produced with a faradic current that discharges sparks from the electrode to the skin.

Nov. 10.—Faradic reaction still continues good. There is more sensibility to the current than there was at the last visit.

Nov. 20.—A galvanic current from twenty-four cells produces no reaction in the left forearm, but in the right reaction is obtained with eighteen cells. Faradic reaction is equal on both sides. There is almost complete recovery of voluntary power, except in the supinator longus.

We have in this case of paralysis from pressure upon the musculo-spiral nerve electrical reactions that are peculiar.

With regard to galvanic excitability we have what is usually found after nerve injuries, reaction by the paralyzed muscles to a less current than is necessary to excite the non-paralyzed muscles. But with the

faradic current, which usually produces only a slight reaction, or none, in the paralyzed parts, we have an increased reaction in the paralyzed muscles as compared with those of the normal side, and this, without return of voluntary power for a long period.

The prognosis in injuries of nerves, when, after several weeks, faradic reaction is good, is much more favorable for ultimate recovery than when it is absent, as in the "degeneration reaction," and recovery is apt to be more rapid, though, even in these cases, weeks or months are sometimes required before a cure is effected.

CASE IV.—*Facial Paralysis from Injury*.—Male, *æt.* 39. Came to the clinic Oct. 13, 1876. He was struck seven weeks before, back of the left ear, by a sand-bag, causing unconsciousness and bleeding from the ear. No other fluid was observed to escape. Consciousness was regained in about three hours, and very soon after he heard a noise in his left ear, which was immediately followed by deafness in that ear. On the morning of the third day after injury, he could close his left eye, but at noon was unable to do so, and complete paralysis of all the facial muscles of that side followed. He has had vertigo, with tendency to the left on several occasions; has had no headache; no dysphagia.

Examination showed absolute facial palsy of the left side. The uvula was straight and active. He could not hear a watch tick with the left ear, but could hear a tuning-fork well over the mastoid process and frontal region of both sides. Sensibility of face normal. Electrical treatment with both currents was ordered, and he was directed to wear a supporting wire. This was made of copper, about one-eighth of an inch in diameter, plated with silver. One end was bent in the form of a hook, and placed in the angle of the paralyzed side of the mouth, so as to draw it outward and upward, thus counteracting the non-paralyzed muscles, and putting the mouth in a proper position. This traction was maintained by carrying the other end of the wire upward, across the malar bone, and bending it around the concha of the ear.

October 16.—Slight reaction is obtained with the faradic current in the frontal portion of the occipito-frontalis.

November 3.—No improvement in voluntary power. All the facial muscles respond to the galvanic current to an abnormal degree. With the faradic current there is improved reaction in the occipito-frontalis and corrugator supercilii.

November 8.—The patient can half close his eye, and can raise his eyebrows a trifle. With the faradic current there is distinct reaction in the occipito-frontalis and corrugator supercilii muscles, but no response in the others. He can hear a watch tick over the mastoid process.

November 10.—Contractions are obtained in the occipito-frontalis with the faradic current applied to the nerve, and in the orbicularis oris, with one electrode on the mucous membrane of the lips, and the other on the nerve. There is but little improvement in voluntary power. Since the above was written the patient has almost entirely recovered voluntary power.

CASE V.—*Paralysis from Otitis Media Suppurativa*.—Female, *æt.* 35. Came to the clinic Sept. 20, 1876. Four months previous she "caught cold," and had an attack of otitis media suppurativa of the left side lasting three weeks. On the second day her face was paralyzed on the left side.

Examination showed complete paralysis of the left facial nerve, and a slight deviation of the tongue to the right. Galvanic reaction was obtained in the lower facial muscles with six cells, seven cells actin

well on all muscles of the paralyzed side, with anode on nerve, and cathode on muscle. On the normal side the reaction was not perceived until eight cells were used, these acting on the occipito-frontalis, and orbicularis palpebrarum, eleven cells being required to produce contractions of the lower facial muscles. The contractions on the paralyzed side were slower than those on the normal side.

Treatment with both currents, three times a week, was ordered.

*September 27.*—There is great increase of galvanic reaction on the paralyzed side; no reaction with the faradic current, but some voluntary power about the orbicularis palpebrarum.

*October 18.*—The patient has recovered considerable voluntary power, but the faradic current produces no reaction in the paralyzed muscles.

*November 22.*—There is for the first time faradic reaction in the orbicularis oris, with one electrode on the mucous membrane of the lips, the other one on the nerve. There is almost complete recovery of voluntary power.

*December 5.*—Faradic reaction has returned in all the upper facial muscles, and in the orbicularis oris.

*Remarks.*—Taking a comparative view of the three last cases, we find that in all of them there was increased galvanic reaction; that in Case III. there was increased faradic reaction, but for a long time no return of voluntary power; that in Case IV. there was a slight return of faradic reaction in certain muscles, followed by a partial return of voluntary power in those muscles, all the changes being very slow. In Case V., four months after the attack, there was a rapid return of voluntary power, but no faradic reaction for two months later, then a partial return. In the two cases of facial paralysis we have the so-called *untartungsreaction*, or degeneration reaction of Erb, viz.: absence of muscular contraction, when either current is applied to the nerve-trunk, with preserved, or abnormally great, and qualitatively altered contractility with the galvanic current, and absence of outtractility with the faradic current, when they are applied to the muscles themselves. It is not to be understood that these are the conditions in all stages, or as the parts go on to recovery or to permanent loss of power, we have different reactions accordingly; in the latter case galvanic reaction finally disappears entirely; in the former, a variable return to the normal reaction takes place. The method of conducting an examination in such cases of paralysis is, according to Erb, to test faradic excitability, by applying the induced current in the following manner: First, exciting the affected motor nerve with one electrode—the other is placed upon some indifferent part; and secondly, by applying both electrodes to the palsied muscles themselves. In cases of severe nerve injury, after a few days we obtain no faradic reaction in nerve or muscle, and in slight injury, faradic reaction may be only diminished, or even normal.

We are to test galvanic excitability by first passing downward current through the muscle, both electrodes being placed on the muscle. The strength of the current required to produce contractions must be noted, and in order to observe the qualitative changes referred to we must observe whether the contractions occur on opening or closing of cathode or opening or closing of anode, and if they are obtained in more than one of these conditions, the relative strength of contraction in each should be recorded. In the "degeneration" reaction we obtain, by passing a galvanic current through the muscle, an anodal closing contraction equal to or greater than the cathodal closing

contraction, and a cathodal opening contraction equal to the anodal opening contraction, the contractions being slow and tonic; while the law of normal contraction is contraction on cathodal closing and anodal opening, though it is modified by the strength of the current. The contractions are quick and clonic. After testing the muscle in the manner described, we repeat the method, except that this time both electrodes are placed on the nerve-trunk above the muscle.

## Reports of Societies.

### ILLINOIS STATE MEDICAL SOCIETY.

(Special Report for MEDICAL RECORD.)

THE regular annual meeting of the Illinois State Medical Society was held at Chicago, May 15, 16, and 17.

The time was taken up with the usual array of business—the reading of papers, their very hasty and unfinished discussion, the making of reports, elections, and in the way of entertainment a banquet on the evening of the second day, tendered by the local profession to the members from abroad.

#### THE STATE BOARD OF HEALTH.

DR. E. W. GRAY, of Bloomington, from a committee appointed to urge the Legislature to establish a State Board of Health, reported that the present legislature were sure to pass the bill originally presented to them, shorn, however, of all its essential provisions except these: 1. In the appointment of a State Board; 2. For the expenditure of five thousand dollars in two years for the expenses of the work; 3. For authority to compel the registration of births, marriages, and deaths. All authority to make investigations or establish any sanitary regulations further than these had been stricken from the bill.

DR. N. S. REED read a report on Practical Medicine.

#### DRAINAGE IN EMPYEMA.

DR. E. F. INGALLS read a very creditable paper on the treatment of empyema by the introduction of a drainage-tube without the admission of air either in the operation or subsequently. The tube is introduced, by his plan, through a canula after the latter has been introduced in the usual way with a trocar, and while the pus is flowing through the canula—the tube (of rubber) being full to the very end of water. The canula is then withdrawn and the tube left in the chest. A piece of sheet rubber with a small hole in its centre is then passed over the tube and fastened with tapes to the sides—this holds the tube in place. The outer end of the tube is to be kept in water, or kept closed by being fastened in a bent position, and the chest emptied of pus and irrigated through the tube daily by the siphon principle.

#### A BAD RESULT FROM ESMARCI'S BANDAGE.

In a report on Surgery, wherein the improvements witnessed during the year were discussed, Dr. J. L. White, of Bloomington, read a history of a bad result of the use of Esmarch's bandage. A young man, healthy, but perhaps not very vigorous, had contracted early in life an ankylosis of the knee, flexed at a right angle. For its relief an operation was made with the bloodless method. The rubber cord was applied high up on the thigh. For a day and a half after the operation the condition was good. Then the limb became rapidly black, and gangrene was soon established

below the knee. Amputation was now resorted to, when all the connective tissue below the point of affliction of the cord was found to be in a state of incipient gangrene, and the final cut was made close to the body. Death resulted now in one day.

#### MISCELLANEOUS SUBJECTS.

DR. C. T. WILBUR, of the Jacksonville Asylum, read a thorough paper on "Idiocy." He discussed exhaustively the relations of the idiot to society, and his proper education and management.

DR. P. S. HAYES, of Chicago, read a paper on Electro-Therapeutics, devoted chiefly to a review of improvements during the year.

DR. E. M. GRIFFITHS, of Springfield, in a paper on *Materia Medica*, took strong grounds against the use of ready-made prescriptions and pharmacists' formulæ by physicians. He opposed the adoption of the metric system in prescription writing. It was impossible to remember, was cumbersome, and would work blunders in writing and filling prescriptions much more than the system now in vogue.

DR. W. L. RANSOM read a paper on *Apocynum Cannabinum*. He had found it to cause a rapid disappearance of the œdema of general dropsy without increasing the urine, the alvine evacuations, or the perspiration.

#### MORTALITY OF SCARLET FEVER.

DR. CHAS. W. EARLE read a paper on the recent epidemic of scarlet fever in Chicago. The most careful investigation had failed to show a death rate among those who had had this disease of over 12 per cent. His belief was that the figure should be 8½ per cent. In those parts of the city where the sewerage was perfect, the streets all paved, and the alleys kept clean, the mortality was greatest, while in the quarters without sewers or pavements, with stinking cess-pools, and in close contiguity to packing-houses and rendering establishments, the mortality was the least. The free use of sulpho-carbolate of sodium as a prophylactic had injured many children, and predisposed them to attacks of the disease.

DR. J. H. HOLLISTER read a paper on the "Dietetics and Hygiene of Children"—really a small treatise in itself—and Dr. Mathews, of Carlinville, read a paper on Congenital Phymosis and Nervous Phenomena Resulting therefrom.

#### A CASE OF MURDER, WITH QUERIES.

DR. A. C. CORR, of Carlinville, sent to be read a history of a case of murder, with some queries.

Called to the case in question early in the morning, he found a man dead, with the jugular vein and carotid artery of one side both severed by a cut; a child of five dead with its skull crushed in; a woman, the wife and mother, insensible and nearly dead, with skull broken as by a blow, a deep gash on the side of the face, with the malar bone and external angular process of the temporal bone crushed in, and the eye-ball burst, and with a portion of the scalp on the crown carried away by what was evidently a charge from a shot-gun at short range, as the skull was denuded and the edges of the skin and hair round about burnt—beside other injuries. A bloody butcher-knife was found on the floor, also a shot gun smashed in pieces, apparently by having been used as an instrument for pounding, *i. e.*, dealing blows. The man and child were in their night-clothes; the woman was dressed in her ordinary clothes.

The woman is recovering. On regaining consciousness she declares she does not believe her husband did

the deed, and that she remembers nothing from the time she *undressed*, and with her family retired for the night before the murder until days afterward. She is under arrest for the crime herself.

The queries are: Could such injuries as the woman received have destroyed her memory of the events of that night, while allowing her to recall all previous to going to bed? 2. Could a man with two main vessels of his neck cut across have time before sinking from the loss of blood to inflict such injuries on another as this woman received?

DR. J. L. HAYES, of Paris, read a paper on Ophthalmology; DR. E. L. HOLMES, of Chicago, one on "Foreign Bodies in the Globe of the Eye," and DR. S. O. RITCHIE one on "Diseases of the Middle Ear in Connection with Nasal and Pharyngeal Inflammation."

DR. J. S. JEWELL read a paper on "The Influence of the Nerves over Nutrition," and DR. S. J. JONES one on "Diseases of the Eye and Ear."

The following named officers were elected for the ensuing year:

*President*—J. L. White, of Bloomington; *First Vice-President*—E. P. Cook, Mendota; *Second Vice-President*—B. M. Griffith, Springfield; *Treasurer*—John H. Hollister, Chicago; *Assistant Secretary*—H. B. Buck, Springfield.

#### NEW YORK PATHOLOGICAL SOCIETY.

*Stated Meeting, April 11, 1877.*

DR. E. G. JANEWAY, PRESIDENT, IN THE CHAIR.

DR. W. T. BULL exhibited a specimen of loose cartilage removed from the knee-joint of a patient aged twenty years. An incision was made directly upon the part, and the wound was closed by the use of the antiseptic dressing. The patient left the hospital on the eighth day perfectly cured.

#### URETHRAL CALCULI.

DR. E. MASON presented two urethral calculi, removed by operation from a patient of Roosevelt Hospital. Four years ago the said patient had been operated upon by Dr. Eager, for stricture of the urethra, and two years ago he came under the observation of Dr. Mason at Roosevelt Hospital, with several of these strictures, one of which, situated in the membranobulbous portion, was impassable. He refused an operation at that time, and did not place himself under treatment again until November, 1876. At that time he had several sinuses in the perineum, through which most of his urine found exit. December 5th, on attempting to introduce a sound, a calculus was detected at the peno-scrotal junction. The operation of perineal section was performed and all the strictures divided. Two calculi were thus discovered in the urethra; the smaller, weighing three grains, was in the portion of the urethra indicated; the larger, weighing a scruple, and of the diameter and shape of a stem of a clay pipe, was discovered between two strictures.

#### SPECIMENS FROM A CENTENARIAN.

DR. A. H. SMITH presented specimens from the body of Capt. Labrbush, who was said to have lived to the age of 111 years and 25 days. He had enjoyed very good health, with the exception of habitual constipation, up to a short period of his final illness. He had been in the habit for many years of consuming large quantities of opium, and during a considerable period taken as much as a drachm and a half daily. On January 21st, after an exposure to very severe weather he was seized with an attack of congestion of the lungs.

accompanied with intense dyspnoea. He rallied somewhat from this, but continued in a more or less weakened condition until the close of his life.

A fortnight previous to his death, his right thigh was found to be enlarging. On careful examination, this enlargement was made out to be an abscess, which, becoming painful and showing a marked disposition to increase, was aspirated. The operation was necessitated three days in succession, and the quantities of brownish fluid which were withdrawn were respectively, 18, 12, and 8 ounces. After the last tapping, there did not seem to be much effort at refilling.

During his last illness there was also discovered on the right side of the abdomen a large painless tumor about midway between the lower border of the ribs and the crest of the ilium.

The patient died April 3d, of asthenia.

At the autopsy, the abdominal tumor was found to be the size of a child's head, and occupied the place of the kidney of that side. It proved to be a cyst filled with a material resembling hashed liver. Under this sac and connected with it was another of similar contents and of similar appearance. The growths were very slightly adherent to the intestines. The inner and posterior portions were attached to the spinal column by means of a cord, which appeared to be the remains of the renal vessels of that side.

An examination of the tumor of the thigh disclosed the existence of an abscess formed of three cysts, lying underneath the vastus externus muscle. The contents of these cysts were very nearly the same as those found in the abdomen.

The left kidney was somewhat diminished in size, and presented a number of cysts on the surface. The capsule was easily stripped. In some places the cortical substance was almost entirely gone. During his lifetime, however, there was never any evidence of insufficient performance of the renal function. The liver was somewhat smaller than natural, positively fatty, very friable. The substance of the right lobe contained numerous small transparent cysts. Heart fatty, valves normal. Arch of aorta enormously distended, filled with calcareous patches; in some places the walls of the artery were almost penetrated by ulcerations.

Lungs were in good condition. There were no pleuritic adhesions, except to the diaphragm. On opening the chest the softness of the ribs was marked, the knife cutting through them like cartilage. The skin was in the same condition, no more resistance being made to the needle than would be afforded by a soft towel.

DR. JANEWAY thought that the tumor in the thigh was an old hematoma.

**CARIES OF THE LUMBAR VERTEBRÆ SACRUM, ILIUM, AND SACRO-ILIAC ARTICULATION—PERFORATION OF SPINAL ABSCESS INTO THE SPINAL CANAL—CEREBRO SPINAL MENINGITIS.**

DR. SATTERTHWAITE presented portions of the sacrum and ilium, with the following history: F. M., *et.* 34, New York, was admitted into the Presbyterian Hospital, Dec. 24, 1876. Eighteen months previously a large swelling made its appearance on the right side of the abdomen, extending, according to the patient's description, from the crest of the ilium downwards and backwards towards the spine. Eight weeks later this swelling was lanced and a large amount of matter escaped. The wound did not heal, and the discharge was constant. The treatment had consisted of injections of carbolic and salicylic acid solutions.

On admission to the hospital a sinus was discovered

over the crest of the ilium about five inches from the posterior superior spine. It led to eroded bone, and then, extending inwardly and backwards, ran towards the vertebral column. Two days later the sinus was enlarged, in order that the parts might be more thoroughly explored, and sponge-tents were introduced, but, as they gave rise to severe pain, were subsequently removed. A few days later (Dec. 29th) extensive crucial incisions were made, and it was then found that fistulous tracks extended under the iliacus muscle.

The case was regarded as one of spinal abscess, though the exact bony points involved were not evident. The patient's health, which had before been delicate, now began to fail, and on Jan. 2, 1877, he had severe chills, followed by fever, with a temperature of 102°. He became very restless, and complained of pain along the spine, increased on pressure, so that he lay either upon his side or abdomen. He also had severe headache. On the next day he became delirious, his tongue was tremulous, and he had muscular twitchings all over the body, well-marked subsultus tendinum, and he picked the bed-clothes. He died at 6.30 p.m. the following day. It was observed at the time of his admission to the hospital that he walked like a drunken man—he complained of "pins and needles" in his legs and feet. There was at no time tenderness over the sacro-iliac junction, or on pressing the ilia together. He had no difficulty in urinating, or in having motions from the bowel. There was also no difference observed in the relations of the thigh, so far as abduction or rotation outwards was concerned.

At the post-mortem examination it was found that the exposed bone upon the crest of the right ilium was about two inches in length and the breadth of the crest; from this point a sinus led backwards and downwards along the anterior face of the posterior portion of the ilium to a point between the fourth and fifth lumbar vertebrae, and the anterior surfaces of the bodies, fourth and fifth lumbar and part of the first sacral being bare. There was no displacement of the bony parts, but portions of the last lumbar vertebra were loose and nearly detached. In separating the sacrum from the ilium there was a small spot of carious bone upon the opposed surfaces the size of a three-cent piece. At the junction of the fourth and fifth lumbar vertebra perforation had taken place into the spinal canal, and pus had entered. Beneath the dura mater the cord was found to be covered with a thick fibro-purulent deposit, which extended for its whole length. The brain was covered by a large collection of serous fluid, in which there was pus and numerous flocculi of lymph. The veins of the membranes were filled with blood. The lungs contained numerous small cavities and calcareous nodules, around which was circumscribed pneumonia. The liver was waxy. The kidneys presented no noticeable change. As for the cause of the caries the patient referred it to a fall which he had received some two years before the first manifestations of the symptoms. The case was regarded as interesting in showing an unusual mode in which death may be brought about in Pott's disease. It was presumed that the fatal issue was due to the passage of pus into the spinal canal, setting up primarily inflammation of the meninges of the cord. The small amount of disease at the sacro-iliac articulation would account for the absence of symptoms indicating sacro-iliac disease.

**CARIES OF LUMBAR AND SACRAL VERTEBRÆ—DOUBLE Psoas Abscess.**

Dr. Satterthwaite also presented a specimen of

carious lumbar vertebrae with the following history:

B. A. A., 31, Louisiana, single; was admitted into the Presbyterian Hospital April 20, 1875. His disease first manifested itself by pain in the back, occurring some six or eight months previously. He then commenced to lose health and strength, and a large swelling appeared in the right groin. When received into the hospital he was hardly able to stand, and he had the sensation of "pins and needles" in his legs, this feeling having become more intense latterly. There was also a large swelling on the inner side of the right thigh and in the right iliac region. Openings were made, and the patient experienced relief from the sensations already alluded to, though his health gradually failed, and he died August 31, 1875. At the autopsy it was found that the second, third, fourth, and fifth lumbar vertebrae were somewhat excavated posteriorly and the cavities were filled with pus. Exit was found by perforations of the psoas muscle on each side. On the right side it pushed down between the deep layer of the superficial fascia and the gluteal muscles, and then penetrated the fascia lata; then followed that tissue round to the inner aspect of the thigh. Another sinus upon the same side also led up to the skin below Ponpart's ligament. On the left side the matter penetrated the psoas muscle, and passing down the substance of the muscle reached the skin below Poupart's ligament. The case was interesting as showing the courses that matter may take when there is caries of the lower lumbar and sacral vertebrae.

## NEW YORK ACADEMY OF MEDICINE.

*Stated Meeting, May 3, 1877.*

DR. S. S. PURPLE, PRESIDENT, IN THE CHAIR.

### REPORT ON PHIMOSIS.

DR. L. M. YALE made a valuable report on phimosis from the Surgical Section to the Academy. The reporter accepted the definition now generally given—namely, "a condition of the penis in which it is impossible to retract the prepuce behind the glans." The following propositions were submitted:

*Proposition I.*—*In childhood phimosis was the rule, and might be considered as physiological.*

The frequency of phimosis was believed to be a commonly accepted fact. No one could have failed to observe how rarely the glans was seen uncovered in young children, even when the penis was in a state of erection.

Such inability to uncover the glans was frequently due to the length of the prepuce, and to the narrowness of its orifice alone.

This condition had been noticed in cases in which free sweep of a probe could be made beneath the foreskin quite to the sulcus; in cases of so-called "ballooning" of the prepuce, and notably in certain cases occurring in adolescents, where a narrow and somewhat tortuous outlet, admitting with difficulty an ordinary probe, rendered micturition slow and difficult. It was believed that, as a rule, adhesions in the sense of agglutination of the two epithelial surfaces existed in phimosis, and that in most cases they constituted the real difficulty to be overcome.

*Proposition II.*—*Phimosis, by its unusual severity or persistence, might become pathological, and might give rise to disturbances both local and remote.*

The local disorders included:

1. Those which were purely mechanical in their nature, such as interference with the proper develop-

ment of the genitals (not common); difficult (common) or intermittent micturition (less common); or even total retention of urine (occasional); retention of secretions beneath the prepuce.

2. The direct result of the mechanical irritation, or obstruction, such as itching of the glans (very common, and might give rise to masturbation); pain; balanitis (frequent); straining to void urine, and consequent prolapsus recti and hernia.

3. Genito-urinary symptoms, not directly mechanical, such as priapism, and incontinence of urine (most common of all); vesical irritation, or tenesmus; hæmaturia, and, in adult life, erotic dreams, seminal emissions, painful and unsatisfactory coitus. Incontinence of urine so commonly depended upon phimosis, that the latter condition should be corrected before resorting to other treatment. *The remote phenomena* included general disorders of the nervous system, and among such were mentioned gastralgia, neuralgia, amblyopia, "reflex paralysis," paresis, inco-ordination.

The earliest references to such a cause for nervous disarrangement that the reporter had met with were in Dr. Bumstead's work on venereal diseases. Those references were to articles published by Fleury and others, and the neuroses specified were gastralgia, neuralgia, and amblyopia.

Reference was then made to the cases reported to the American Medical Association by Dr. Sayre, of New York, in 1870, under the title, "Partial Paralysis from Reflex Irritation caused by Congenital Phimosis and Adherent Prepuce."

In a paper read before the New York Academy of Medicine in 1874, Dr. F. N. Otis of New York reported a large number of cases illustrating "Reflex Irritations throughout the Genito-Urinary Tract, resulting from Contraction of the Urethra at or near the Meatus Urinarius."

In 1875, Dr. Sayre, in a paper before the American Medical Association, reported additional cases illustrating retention of urine with partial paraplegia, enuresis with hebetude, incontinence with paraplegia, all relieved by removing the phimosis.

Dr. Jas. S. Green had reported a case of "hyperæsthesia of the skin over the whole body, very marked, want of co-ordination of motion in the arms and hands, and great difficulty in walking." The case grew worse for three years, in spite of treatment. Circumcision was followed by relief of the hyperæsthesia within a few hours, and in forty-eight hours, the use of the limbs had been recovered entirely.

The form of nervous disturbance observed in this class of cases had been notably inco-ordination of muscular movements, including those necessary to speech, less commonly spasm or spastic contraction, and paresis, usually of the lower extremities.

The reporter had not found the record of any case of paralysis of sensation, but hyperæsthesia was often mentioned. Several cases of amblyopia had been reported.

A mental condition resembling hysteria or hypochondriasis was a frequent element in the clinical histories. In the collection of cases, of course those only should be admitted in which relief of the phimosis was followed by marked and speedy amelioration of the symptoms. Another point more difficult of determination was whether, in a given case, the neurosis depended upon the phimosis *per se*, or, as suggested by Dr. Jacobi, upon "the habit of masturbation so easily contracted when the phimosis is marked enough to prove an annoyance and irritation, and frequently given up when the source of constant irritation

has been removed." It was not claimed that cases of reflex disturbances remote from the genito-urinary organs were very frequent, but simply that, setting aside the cases which were, for the reasons stated, doubtful, there remained a sufficiently large number to give phimosis a place as a recognized cause of neurosis, and one which should not be overlooked in making out the etiology of a given case. It was only fair to consider cases in which relief of the phimosis alone had been followed by immediate cessation of the nervous symptoms as evidence of the dependence of the latter upon the former condition. It might be safe, however, to go beyond that, and whenever there was marked irritation of the genitals with phimosis, even if it was not believed that the condition of the prepuce was the sole or main cause of the coexisting neurosis, where, indeed, it was quite certain that the nervous manifestations, or the intellectual deficiency, was due to causes beyond our reach, it might be safely assumed that the relief of the phimosis would be productive of benefit. The removal of a source of irritation would probably be followed by the subsidence of such aggravation of the prime trouble as had been due to such local cause, and the prompting to masturbation much diminished.

It was to be remembered that the amount of remote nervous disturbance was by no means proportionate to the apparent local irritation. A case in illustration was reported, in which almost constant priapism was the chief symptom; the boy was also restless in his sleep and micturition tardy. Circumcision relieved all the local symptoms, and the child slept quietly directly after the operation. With regard to treatment, reference was made to breaking up adhesions, the forcible retraction of the prepuce with or without division, division of the preputial orifice, and complete circumcision.

Bokai, who only interfered when there was pathological symptoms, relied solely upon retraction, breaking up the adhesions with a probe or other suitable instrument. Inflation of the prepuce with water forced from a syringe had been recommended for the same purpose. Dr. Holgate had found forcible retraction sufficient; the glans, after being cleaned of smegma, was anointed, and the prepuce again brought forward. The manoeuvre was to be repeated daily by the surgeon or attendant. If the prepuce was redundant, circumcision was thought to be the preferable operation.

Splitting of the prepuce might be done to assist the retraction. In adolescents or in children, when the prepuce had been the seat of much inflammatory process, the knife would be generally needed in one method or the other.

Notes of twelve cases of nervous derangements, dependent upon phimosis, and relieved by circumcision, by Dr. James S. Green, of Elizabeth, N. J., accompanied the paper.

DR. LEWIS A. SAYRE reported several cases in which rapid and marked amelioration of nervous symptoms had followed circumcision.

DR. F. N. OTIS contributed corroborated evidence regarding the effect of phimosis upon a peculiar condition of sexual weakness, either associated with seminal loss or otherwise. He had had his attention drawn to it at difficulty as aggravated if not produced by the retention of a redundant prepuce. Reference was made to a case then under observation. The patient, an adult, had been suffering from seminal loss for a long period, and had been treated for spermatorrhœa according to the most approved plans both in this country and in Europe, and with the result only of

affording temporary relief. All local applications seemed to aggravate his trouble. He became very despondent, and among other things which affected him unpleasantly was his complete inability to ride on horseback, for he had been very fond of such exercise. His despondency increased; he had more or less passage of seminal fluid with the urine; and erection was imperfect. When he came under the care of Dr. Otis, he was in a state of mind bordering on melancholia. The prepuce was long, the glans penis sodden, because of being kept constantly ploughed by a redundant prepuce, and there was a slight stricture at about one-third of an inch from the meatus, and which contracted the urethra about one-fourth of its calibre.

On learning that all ordinary treatment in his case had failed, the operation of circumcision was recommended. The recommendation was accepted; the operation was performed, and the stricture also was divided. His mental condition immediately began to improve; his seminal loss was evidently less, and with occasional injections over the seminal ducts, together with treatment very much milder than that to which he had been subjected, he gradually recovered his strength, became more cheerful, and finally made an apparently complete recovery. It was Dr. Otis's opinion that redundant prepuce, associated with seminal loss and sexual weakness, was very frequently overlooked, and failed to receive the attention which its real importance required. He had found it a particular element in producing a melancholic state of mind.

It was the Doctor's opinion that, when such a condition existed, a long prepuce and sodden condition of the glans, there was a nervous loss occasioned, a leading off of some nerve-power, as it were, by some abnormal communication; that there was a positive and constant nervous loss which these patients underwent; that such loss was arrested by the means already mentioned; and that it was the correct and scientific manner for affording relief, from the fact that the conditions, mental and otherwise, were promptly improved by such procedure.

The Academy then adjourned.

## NEW YORK MEDICAL JOURNAL ASSOCIATION.

*Stated Meeting, May 4, 1877.*

DR. CHARLES M. ALLIN, PRESIDENT, IN THE CHAIR.  
THE THERAPEUTICS OF HEADACHE.

DR. EUGENE DUPUY addressed the Association upon the above subject; restricting his remarks to *migraine*. Such headache appeared in the human species, manifesting itself in some and not in others, because the membranes of the brain in the neighborhood of the pons were in a state of chronic preparation for its development. Although the headache was not continuous, the condition was there necessary to its development after the action of some exciting cause. The condition indicated was a moderate inflammatory state or a severe congestion of the meninges about the pons. The headache usually showed itself after gastric disturbances of various forms, after improper use of alcohol, etc. Affections of the liver had the power to arouse the latent influence into action and so develop that form of headache. Fatigue or overwork might be exciting causes.

Such headaches never appeared spontaneously.

## MEANS FOR ARRESTING HEADACHE.

It was believed to be possible to cut short the attack, to destroy it altogether, by resorting to some one of the following measures:

The means which might succeed in one case might fail in another. The most successful means were those which acted in a reflex manner. For instance, irritation of peripheral nerves, such as might be brought about by introducing alcoholic liquors, like brandy, or strong snuff into the nostril upon the side corresponding with that to which the pain was referred, would check the headache. In other words, irritation of the mucous membrane of the nose could be resorted to with benefit. The remedy to which special attention was directed was

## CARBONIC ACID GAS

thrown against the nasal mucous membrane in a jet sufficiently strong to produce a marked impression. Such an exhibition of the gas seldom failed to remove the pain within two or three minutes after its application. A sharp occipital pain was produced in those cases in which the remedy was to afford relief, so that the failure to develop such pain was regarded as a warrant for the second introduction of the gas. In the headache symptomatic of fever or the headache of hysterical persons this remedy did not succeed.

Another remedy believed to be very efficacious in the treatment of an attack of *migraine* was the

## POTION OF RIVIERUS,

to which was added bromide of potassium. The potion consisted of citric acid and simple syrup, and bicarbonate of potassa and water. It was an effervescing mixture, and was recommended to be administered in alternate tablespoonfuls, allowing the effervescence to take place in the stomach.

Those were the chief means mentioned for checking the attack of sick headache, and the mode in which they acted was to remove the irritation from the tract of the middle encephalon, where the roots of the fifth nerve had their origin. The cause was an alteration of nutrition, especially in the way of congestion, brought on by irritation of the meninges. The substances recommended produced their good effects by arresting the influence exerted by that morbid state.

## TREATMENT PROPER.

No rule could be given with reference to treatment during the interval between the attacks. The treatment should be directed towards producing changes in the nervous centres mentioned. The exhibition of arsenic to such an extent as to produce slight oedema of the lower eyelids would sometimes remove the attacks for a long time. It was believed to be also necessary to give belladonna at times sufficient to produce its physiological effect. Occasional mustard plasters to the nape of the neck and the use of mild aloetic aperients were recommended. The cannabis indica had a strong curative effect upon the form of headache under consideration. It might with advantage be alternated with valerian or tannin. The rheumatic, gouty, and syphilitic diathesis must be studied, and appropriate remedies administered.

Dr. E. C. SEGUIN referred to one method of combating headache which had not been mentioned by Dr. Dupuy, and that was the use of paullinia powders or their equivalent, the elixir or fluid extract of guarana. When the patient awoke in the morning with a feeling as though a headache was coming on, he should take half a powder or a drachm of the fluid preparation, and repeat it in the course of an hour if

relief was not obtained by the first dose. The first dose should be taken as early as possible.

Dr. Seguin remarked that he did not hesitate to use hypodermic injection of atropia and morphia, one-hundredth of a grain of the former combined with from five to fifteen minims of Magendie's solution of morphia, when the pain was severe.

With respect to the treatment of the disease in the interval, he had seen excellent results follow the administration of one-half grain of the solid extract of cannabis indica to an adult male daily, and one-third of a grain for an adult female, and continued so as to keep up the continuous effect of the drug for a long time. With regard to the nature of migraine, Dr. Seguin firmly believed it to be a neurosis, and not an expression of appreciable organic change. That view was regarded as more tenable than the one advanced by Dr. Dupuy. He was not able to understand how the patients could be perfectly well, as they were in the interval, if the headache was dependent upon a sub-acute inflammatory action, or truly great hyperemia of the membranes of the brain. It would seem as though there would be, were such the case, a certain amount of morbid manifestation after the attack. The theory also failed to explain why the pain was as localized as it was, and also why, with congestion of the meninges, there should be no facial pain, the pain of migraine usually being cranial. Another peculiarity of migraine was that it was periodical in its appearance, and had a close alliance to epilepsy. Epilepsy and migraine were very apt to be associated, and in some attacks of sick headache there were almost epileptic manifestations.

Dr. DUPUY replied with reference to the use of hypodermic injections of morphia and atropia that, in his experience, they had almost invariably been followed by vomiting, which kept the patient sick an extra day; hence, he did not recommend their use. With regard to paullinia, it was at one time very popular as a remedy for the cure of headache, but he was sceptical regarding its real value. It checked the headache indeed, but, according to his experience, was not nearly so certain to do so as the remedies which he had mentioned. With regard to the existence of subacute inflammation of the membranes of the brain being consistent with the enjoyment of apparently perfect health, cases were exceedingly numerous in which such was the case, and as an illustration reference was made to epilepsy. In that disease there was found thickening and evidences of subacute inflammation of the membranes at the base of the brain, and yet the patients were bright and intellectual during the interval between the attacks.

Dr. G. M. BEARD was inclined to doubt the soundness of Dr. Seguin's view regarding the relation existing between epilepsy and sick headache. Take, for example, one hundred cases of sick headache, and probably not more than one out of fifty had any relation to epilepsy whatever. The families were so rare in which both epilepsy and sick headache were found that it could hardly be made available as an argument in favor of the neurotic theory of the disease. It was pretty clear to Dr. Beard's mind that sick headache was a safety-valve to the system, and that those who had the attacks should be thankful for them. They were believed to be vicarious, and acted in the way of preventing the development of some more serious trouble. For cases were not infrequent in which sick headache had left the patient, and been followed by a more serious disturbance, like apoplexy.

With regard to treatment, caffeine had, in his hands, given more satisfactory results than the paullinia. 1

was administered in that period of indefinite misery just before the attack came on.

From fifteen to twenty grains of muriate of ammonia in water had sometimes worked as favorably as the caffeine.

A combination of carbonate of ammonia, caffeine, and elixir of guarana sometimes acted favorably when neither of the remedies mentioned were of service, administered alone. He regarded the remedies mentioned as much better than hypodermic injections of morphia and atropia; the results did not seem to be satisfactory when the injections were employed, and there was greater liability that the attack might return.

After some further discussion relating to the pathology of the affection, the Association adjourned.

## Correspondence.

### MEDICAL MATTERS IN CHICAGO.

THE COMING MEETING OF THE AMERICAN MEDICAL ASSOCIATION—THE PROSPECTIVE PHARMACOPEIA—WOMAN DELEGATES—THE NEW DISCOVERER OF ANÆSTHESIA.

(From our Regular Correspondent.)

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—PREPARATIONS for the forthcoming meeting of the American Association are approaching completion. The local committee of arrangements have for some weeks past been busy looking after the various details. The meetings of the association are to be held in Farwell Hall, a place very commodious and central. This hall is large, has a large elevated platform, and a wide gallery on three sides of the room. Perhaps no better could have been chosen for the general meetings. But these yearly sessions of the association are always unpleasantly near failures—if indeed they are not now getting regularly to be such—if proper places of meeting for the several sections are not provided. This time six rooms are provided for the use of sections, all near by the main hall.

The entertainments as so far developed will consist solely in receptions at their residences by a number of our citizens in and out of the profession. On one evening Prof. Ross, Mr. Chr. Hotz, and Mr. Craine, all of the "West Side," will receive; another evening, Prof. Isham and one or more of his neighbors of the "North Side" will do the honors, while the third evening will find the members entertained by some friends of the "South Side," chief among whom will be Prof. Roler.

There has been some talk of an excursion over the Northwestern Railroad, to the company of which Prof. Isham, one of the Committee of Arrangements, is surgeon, but the committee will probably conclude that men coming, many of them, a thousand miles by rail to attend the meeting will hardly be entertained by a further ride on the cars, even though it be called an excursion. Besides, the members of the committee are all of them men who believe that Chicago is such a phenomenon that no sight-seeing outside can at all compare with that which is offered within her limits.

The expectation of a lively time in the Association over the resolutions of Dr. Squibb, regarding the Pharmacopœia, seems to be hereabouts quite general. For the interest of the discussion, however, I regret to say the opinions one hears expressed are nearly one way. While it is strongly hinted that one Philadel-

phia doctor is making annually out of the publication of the Pharmacopœia, under its present management, some thousands of dollars, and while the motives of Dr. Squibb are never called in question, nor an unkind word uttered about him personally, the belief is that his scheme to *assume* the Pharmacopœia is impossible of accomplishment; that it is so thoroughly impracticable, if not in its nature (not its intention) impertinent, that the Association will make short work of it. However, the temper of the body may be wholly different from what these opinions would suggest, and Dr. Squibb may gain authority to publish a second United States Standard. It is impossible to foretell the action of such a mixture as the American Association is getting to be. A strong appeal to feeling under the right circumstances and at the right time, and our heads are gone. The action of last year will be reversed, to be again changed next year under a different set of circumstances.

The history of the question of woman delegates illustrates this fact. Half a dozen years ago the petition for the admission of delegates from a body that *might* some day send a woman was rejected almost unanimously. Again and again this position was reaffirmed. Last year, with the woman on the spot to look her brethren in the face, and the great body of men voted with an affirmative that was vociferous and nearly unanimous, not to refuse her registry. Apropos, Rhode Island is to send as one of her delegates this year a talented woman, while a number of Western delegates are women. Verily, the ice is broken. The Illinois State Society is to be tried for sending a woman delegate to Philadelphia, and the differences between the rival associations of Arkansas, each claiming to be *the* State Society and each demanding to be admitted to representation as such, will have to be settled in some way at this session. The claim comes with more than plausibility that on the latter of these questions the action of the Association last year was inconsistent with its previous action, if not entirely arbitrary and unjust.

Log-rolling has already been begun to determine who shall be the next president. Quite a number of the delegates from the Northwest believe that the Association would honor itself, no less than the city of Chicago, by electing either Prof. Moses Gunn or Prof. Byford; there may be other candidates, but we have not heard of them.

The article of Dr. Marion Sims on the Discovery of Anæsthesia, published in the May number of the *Virginia Medical Monthly*, has just been distributed here. Dr. S. claims, and with the documentary evidence at his back, that Dr. Long, of Georgia, is the first discoverer of the great boon.

He proposes that the whole profession of the country unite in asking Congress to appropriate one hundred thousand dollars to be equally divided between the families of Long, Wells, Morton, and Jackson. Does Dr. Sims intend springing this question at the forthcoming session? The wide distribution of his article at this time is suggestive in this direction. It will certainly do no harm to ask Congress to do something—that is, it will not hurt Congress or the country. The national legislature has been often asked to do things and many things: some of them it has done—perhaps it has done as many things the country has not asked as that it has demanded. But if the Association asks continually for things that are certain to be disallowed, it weakens its influence for those measures that really need Congressional aid and sanction.

But why so beneficently pension the families of

these four men who deserve praise? According to Sims's own showing, the families of Humphrey Davy, Willhite, and Drs. Warren, Hayward, and Bigelow are as deserving of pension. As one reads the history of this great discovery he is impressed with the truth of the old notion that great discoveries come by the progress of knowledge, not by the acts of single men. See what a number of men had actually found anesthesia without being greatly conscious of it! What a hard time this great child had in being born! Perhaps the difficulty was in being adopted, for Davy in 1800 told the world all about it. What have these claimants added to the work of the English chemist? Nothing but that they took his thought just as he gave it and used it, and the masses were astonished and blessed. If these men had never lived, the world's progress had made it inevitable that soon, toward the close of the first half of our century, great numbers of other men would take up and use the idea of Davy. Why not pension all these men who would have used anesthesia had not the four named lived? There is one reason surely, because only these men,—three of them—have identified themselves in their early connection with the new measure, by their bitterness toward each other, and their wholesale denial of each other's claims. All Dr. Sims says of the value of anesthesia is more than true. But we cannot pension the families of all the men who do noble things.

CHICAGO, May 15, 1877.

## ROTARY LATERAL CURVATURE, AND A QUESTION OF PRIORITY.

The following correspondence will explain itself:

"1,503 SPRUCE STREET, PHILADELPHIA, May 15, 1877.

"MY DEAR DOCTOR SAYRE:—I have read with deep interest your remarks made before the Surgical Section of the New York Academy of Medicine, on 'The Treatment of Rotary Lateral Curvature of the Spine,' as reported in THE MEDICAL RECORD for March 31st.

"While expressing my appreciation of your courteous acknowledgment of my own agency in the introduction of 'suspension' in the treatment of spinal affections, and my extreme gratification that a means which I esteem of so great importance, and for which I feel a certain degree of responsibility, should have commended itself so entirely to your mature judgment, allow me to correct an error into which you have unintentionally fallen, and for which I am probably myself to blame.

"In a demonstration of my mode of employing this method, before the Surgical Section of the American Medical Association at the Philadelphia meeting last summer, which, you may remember, I introduced in connection with your valuable paper on the plaster-of-Paris dressing in Pott's disease, I alluded to the fact that Prof. Mitchell had warmly advocated the use of direct extension of the spinal column by suspension, and had met with distinguished success in treating spinal curvatures in this manner. I possibly failed to make it clearly understood that with him the suspension was purely passive. He did not, as you say, 'cause the children to suspend themselves.'

"Whatever of merit there may be in the added idea of *self-suspension*—converting the passive into an active exercise, contributing to the vigor of the thoracic muscles and development of the thoracic cavity, and at the same time placing the force entirely under the control of the patient—I must claim for myself. My revival of Dr. Mitchell's system of suspension dates

back to the year 1865, and was given to the profession in 1867, in a little work entitled 'Contributions to the Pathology, Diagnosis, and Treatment of Angular Curvature of the Spine.' My experiments in *self-suspension* began about the time of the publication of this volume. My first public demonstration of it was made before the Medical Society of the State of Pennsylvania at its meeting in Philadelphia in June, 1870. The lecture then delivered, which was clinically illustrated by three patients who had been successfully treated in this way, appeared in the Philadelphia *Medical Times* for November 15, 1870 (of which I take the liberty of sending you a copy), and was reproduced in a short treatise which I published in 1872, under the title of 'The Correct Principles of Treatment for Angular Curvature of the Spine.'

"Although my object at that time was especially to call attention to the value of this method in spinal caries, I had already used it extensively in true idiopathic lateral curvature, as will be gathered from the following statement at the close of the lecture:

"This mode of treatment is equally applicable to lateral curvature. In the incipency of that affection, indeed, it may unaided be adequate to work a cure. By causing the patient habitually to take hold of the higher handle with the hand corresponding to the depressed shoulder, that shoulder is thus, for the time being, elevated, and its muscles are thrown into more powerful action than those of the opposite side, while the curve of the spinal column, if not too rigid, is entirely reversed, and under any circumstances diminished.

"I think, by the way, that you will find this suggestion of the unequal heights of the hands, which I do not see any allusion to in your remarks as reported, a valuable one.

"Your demonstrations of the increased lung capacity and increased height are as striking and conclusive as they are original. I have applied your plaster-of-Paris jacket in two cases of spinal caries lately (one of them an adult on the brink of the grave, after six years of disease, accompanied much of the time with profuse suppuration), and in both with marked success.

"Congratulating you heartily on this valuable contribution to our art, I am,

Yours truly and fraternally,

BENJ. LEE.

"TO LEWIS A. SAYRE, M.D., Professor of Orthopaedic Surgery, etc., Bellevue Hospital Medical College, New York."

"285 FIFTH AVENUE, NEW YORK, May 17, 1877. 1

"MY DEAR DOCTOR:—I sincerely regret that I should have done you any injustice in my 'Report on Rotary Lateral Curvature' before the Surgical Section of the New York Academy of Medicine. It was altogether unintentional, I assure you, as I was not aware that you had modified the plan of Dr. Mitchell by *self-suspension*, which I think the most important part of the treatment, and shall hereafter give you full credit for being its originator.

"I was unfortunately absent from the meeting in Philadelphia when you made your demonstration, and I understood you to say afterwards, when we were talking over the matter, that you had got the idea from Dr. Mitchell, and in this way I was led into the error, not knowing that you had modified his plan.

"Your paper in the *Medical Times* of 1870 was published when I was abroad, and I unfortunately had not seen it until the copy you sent me to-day.

"For the privilege of making this correction, which I do most cheerfully, I am very much obliged.

"Yours very truly,

"LEWIS A. SAYRE.

"DR. BENJ. LEE."

## CATHETERISM IN PROSTATIC RETENTION.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—IN THE MEDICAL RECORD of May 5th, page 288, Dr. E. L. Keyes, speaking of the vertebrated catheter, says: "This instrument is not without danger, especially in the hands of a patient." And he gives an instance in which "an old man had long used it upon himself, but the chain had broken in two instruments, leaving all the links in the bladder, and still the patient wanted another one."

It is altogether probable that these two instruments were not properly made. Nevertheless, when made in the most perfect manner, the vertebrated catheter, as Dr. Keyes has said, and as I have myself acknowledged (RECORD of January 1, 1873, page 6), is not without danger. There is a certain amount of danger attending the use of any catheter. But the vertebrated instrument is, doubtless, more liable to break than any other variety in use, unless it be the Jaques catheter, which is altogether too brittle in its texture to be used with perfect safety. The dangers attending the use of the vertebrated instrument do not necessarily appertain to the instrument itself, but they are the result of faulty manufacture or of careless use. Every instrument should be made of pure silver, and the material should be thick and heavy. The chain, which is the dangerous part, should be made from large silver wire, and it should be securely anchored in the beak. The rod should be secured upon the edge of the tube at the pavilion by a simple transverse arm, and a movable cap employed by which this arm is made fast. Each instrument should be provided with its own special case, in which it is always kept, in the same manner as the hypodermic syringe has its own proper case, for convenience and for safety. The case for holding the vertebrated catheter should be nine inches long, an inch and a half wide, and an inch thick. The space within should consist of two parallel grooves, one to hold the shaft, and the other to hold the links, the chain, the rod, and the cap. This case is not only very convenient for carrying, but it compels the surgeon to take the instrument apart, and put it together again, every time it is used, during which processes he should always be in the habit of inspecting the reliability of the chain. A case of this kind, which was made for me, in 1873, by W. F. Ford, of New York, holds the catheter which I have for my own use. When called upon to use the instrument, the links of the chain are first inspected, then the different parts are adjusted for use, and after it has been used it is properly cleansed and restored to the case again as before. By being thus careful the liability to accident will be very small.

Inasmuch, however, as we cannot prevent the faulty manufacture and careless use of the instrument, accidents must occasionally occur, unless the catheter—good in itself—be entirely discarded, which will undoubtedly be the case in the future, provided another one can be found equally good and more free from danger.

The meritorious features of the vertebrated catheter, according to my view, are:

1. The highest possible degree of flexibility of the prostatic portion.

2. The limitation of this superlative flexibility to a certain requisite range.

3. The rigidity of the shaft, and the longitudinal stability of the whole instrument.

4. Perfect external smoothness, hemispherical beak, transverse stability and good calibre.

In respect to the first quality there is meant to be no resistance whatever to the lateral instability of the beak, and the floating sections that follow it; the flexibility is meant to be free from even the least restraint. In respect to the second quality, it may be illustrated by reference to some of the attributes of nature. Take, for instance, the spine. Our vertebral columns have the most easy and delicate flexibility possible within certain limits; but, beyond these limits, there is a check. So in the vertebrated catheter, at twelve different points perfect lateral freedom is allowed for a little distance, but no further; and this check prevents the beak from turning backward, and the instrument from doubling on itself. The other virtues of the instrument depend mainly upon the intrinsic qualities of the silver itself.

The fault of the soft rubber catheter is, not that the prostatic portion bends too easily, but that it bends too much. The other portions of the instrument bend too easily; and the whole instrument has insufficient longitudinal stability. The extreme flexibility of the entire instrument, however, becomes a benefit, after the catheter is once introduced, for then it allows the anatomical parts to assume their natural position. Dr. Cowan, of Danville, Ky., was the first to make known a remedy for these defects. He invented and published (*Am. Jour.*, April, 1874) two modifications of the soft rubber catheter, viz.: the permanent use of a compact wire coil in the interior, and the employment of a watch spring stylet. He tested these modifications and found them to be of practical utility.

With a similar purpose in view, Dr. Otis, of New York, has called attention (MEDICAL RECORD, April 21, 1877) to a stylet for this catheter, designed to abridge the flexibility of the prostatic portion, and virtually to nullify, during introduction, the flexibility of the remainder of the instrument. This new stylet, which he names the prostatic guide, consists of a slight steel rod, eight inches in length, tipped with a flexible portion, of a length of five inches, formed by a spiral ribbon, with a solid beak. He has had several opportunities of trying this device, and has thus far found it to work admirably. In theory, this stylet approaches very closely to my idea of what is required, and I shall embrace an early opportunity to make trial of its merits. Dr. Keyes, on his part, says that, for a couple of years, he has been using as a stylet for this catheter a twisted rope made of one central and eight encircling very fine wires, and this he has found to do all that was required. The action of this stylet must be very similar to that of the coil suggested by Dr. Cowan, as the mechanism is about the same, and the fact that it has been serviceable in use adds to our store of evidence that some such device is needed to supplement the virtues of the soft rubber instrument.

But we have reason to believe that, with respect to catheterism, there are two classes of prostatic retention. In one class the urethra is only characterized by increased length, and by some abnormal curves that do not reach the nature of a right angle or a *cul-de-sac*, and in these cases a proper flexible instrument will pass into the bladder without resistance. In the other class the abnormal curves are tantamount to a right angle, a projecting shelf, or a *cul-de-sac*, and here there is a physical impossibility to the advancement of

the beak of the flexible catheter; but a suitable rigid instrument, in skilful hands, will generally succeed. A few exceptional cases of this second class may, in the present state of our knowledge, foil every effort at catheterism, and call for the aspirator.

For the cases of this second class the common gum elastic catheter, with a suitable stylet, is the instrument to be used, and very much will depend upon the particular curve given to the catheter by the stylet. In the *American Journal of the Medical Sciences* for July, 1876, I have made known a special curve, which has enabled me to succeed in three very difficult cases where all other expedients failed. This whole subject invites still further study, and, doubtless, the future will furnish still other improvements, in both the flexible and the rigid catheters, employed for the relief of prostatic retention. T. H. SQUIRE, M.D.

ELMHRA, N. Y.

### UNUSUALLY UNPLEASANT EFFECTS OF SULPHATE OF QUINIA.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—I have had three patients, all ladies, with whom the sulphate of quinia has produced peculiarly unpleasant effects.

Very soon—usually within half an hour, in one case almost immediately—after the medicine was taken the face became suffused with an erythematous eruption, and a tingling, itching sensation, very severe and distressing in its nature, followed and extended over the body and extremities.

The effects produced in the three cases varied somewhat, but mainly were identical with the symptoms of *urticaria ab ingestis*.

Each person thus affected was born and grew to womanhood in the Maumee Valley, Ohio, a very malarious region, where they had, early in life every year, taken fully the average quantity of the medicine for such region with the usual good effect.

In case first, the peculiar effect was first experienced just after her second childbirth, about twelve years ago. Since that time she has resided five and a half years in Milwaukee, Wis., where her physician, not knowing her acquired idiosyncrasy, or being incredulous, desired to test it, prescribed a disguised preparation of cinchona bark in tonic doses, with the same result. After her return to the Maumee Valley—six or seven years since—I have at long intervals prescribed the various preparations from the barks unknown to her, and invariably with the same result, the less active preparations being the more slow in their effect. In this case nausea, vomiting, and great gastric distress followed the cutaneous irritation.

In case second there was produced considerable oedema with wheals, ending with desquamation. The idiosyncrasy first manifested itself in this patient four and a half years ago, and has recurred since with the use of the medicine.

Case third was an unmarried woman, twenty years of age, with whom the first unpleasant effects were observed about three years ago. With her the cutaneous eruption and irritation were not so severe as with the others, but the pulmonary oppression and constriction of the throat were the more prominent symptoms.

This patient resided about twenty miles from my office, and was lost sight of after a few visits.

In all of these cases the severe effects lasted several hours, and generally considerable annoyance was experienced during two or three days.

These ladies have enjoyed average good health, have never suffered any particular disease or irritability of the stomach or cuticle, nor has anything ever

produced the same effect as the cinchona barks and their alkaloids, the peculiar action of which must be ascribed to an acquired idiosyncrasy.

Whether it will prove permanent or not in the cases where it has continued several years, may never be known, as the ladies declare that no consideration will induce them to take another grain of the medicine which has caused them so much suffering.

CHARLES E. SLOCUM.

DEFIANCE, OHIO.

### UNILATERAL ACTION OF BELLADONNA.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—Two interesting cases of one-sided action of belladonna have come to my notice; one in my own practice, and the other in that of Dr. David Webster. I will give them as follows:

In August of 1876, a young Irish domestic of the better class, came to the clinic complaining of tinnitus aurium in one ear. She was very nervous and excitable, being unable to tell her symptoms without bursting into tears, although she was not a weak-minded woman, and was evidently striving against her inclinations; said she felt sleepy and dull during the day, and was continually gaping; though when in bed she was unable to sleep. I found a strong venous hum over the jugular, but could distinguish no bellows murmur at the base of the heart. She was evidently, and had all the appearances of being, *anemic* but not chlorotic.

The tinnitus in this case being marked, it was decided to try a suggestion of Dr. E. C. Seguin, that of instilling a solution of atropiæ sulphas into the affected ear. I cannot say that there were positive indications for the use of atropia, for I imagine that it would only act by paralyzing the tensor tympani and in this case there was no tense condition of the muscle observable. She was given a solution of atropiæ sulphas gr. iv. ad ℥i., to be instilled into the ear daily. In twelve days she returned considerably disturbed in mind, saying she could not see well with the eye upon the *same side* as the ear in which the atropia had been used. It was examined and found to be strongly under the action of atropia, the other eye being normal. She was told to discontinue application to the ear, but did not again appear at the clinic.

In December, 1876, A. D.—, widow, age thirty seven, came to Dr. Agnew's clinic, at the Manhattan Eye and Ear Hospital, complaining of affection of one eye.

The history was that she had been under the care of a doctor at some dispensary in the city for trouble with her lungs; had a cough and at one time had raised blood.

About one month before she had been seized with pain in her *right side*, and upon going to the doctor was given a plaster to apply to the affected part. In four or five days after this application she began to have difficulty in seeing with her *right eye*, being the eye upon the same side of the body to which the plaster had been applied, and this difficulty had continued up to and was present at the time she was seen, the plaster still remaining upon her side. Upon examination the pupil was seen to be considerably enlarged, and the eye was undoubtedly strongly under the action of belladonna, the left eye being normal.

The peculiarity of these two cases rests in the fact that in each case the drug must have been absorbed into the general system, and yet only gave this one-sided evidence of its action.

J. OSCROFT TANSLEY.

Obituary.

PROF. CHARLES A. BUDD, A.M., M.D.

PROF. CHARLES ARMS BUDD died in this, the city of his birth, on the 17th of the present month, after severe and protracted suffering, having fallen upon the very threshold of his reputation.

The youngest son of the late Dr. Bernard W. Budd, a widely-known practitioner of "Old New York;" he was born January 16, 1832, received his baccalaureate degree in 1850 from the University of this city, and two years afterward was graduated from the Medical Department of the same institution. An enthusiastic student of the obstetrical art, he was elected, at quite an early period in his career, a member of the faculty of the New York Medical College, and soon took rank as an able and attractive lecturer. The charter of this college having been surrendered, he accepted a corresponding position in the University Medical College as successor to Prof. Bedford, and held the same until the past year, when failing health compelled his retirement to the grade of Emeritus Professor.

Six years ago, while crossing the Atlantic, he was thrown upon the deck of the vessel, and struck in the neighborhood of the knee. A popliteal aneurism formed, which for a long time confined him to his room. His health steadily failed from that time, and three years ago revealed an aneurism of the thoracic aorta. Since then he was a great sufferer, yet has continued manfully at his duties, both professional and collegiate. For the last year he has been very feeble, yet continued at his work, visiting his patients two days previous to his death. The immediate cause of his death was a rupture of the aneurismal sac into the pleural cavity.

Dr. Budd was a member of various medical organizations, but gave his best energies to the New York Obstetrical Society, over whose deliberations he at one time presided. An exceedingly active practice debarred him from many opportunities for distinction in his profession, especially in its literature, since he wrote not at all. Clear, methodical, painstaking, and analytical, in the lecture-room he was a favorite with his classes; quick of perception, cool in the presence of danger, and of an eminently practical mind, he was eagerly sought for in consultations, while to the profession at large he was kindly known for his quaint humor, his lively imagination, his apt anecdotes, and rare geniality. In his friendships almost partisan, generous to a fault, an apologetic critic, and in the sick-room unequalled for his welcome sympathies, but little wonder that many regrets follow after his untimely death.

ARMY NEWS.

*Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from May 13 to May 19, 1877.*

The following medical officers are ordered to represent the Medical Department at the annual meeting of the American Medical Association in Chicago, on June 5th next: Surgeon Jos. R. Smith, Surgeon W. C. Spencer, Surgeon J. J. Woodward, Surgeon J. S. Billings. S. O. 106, A. G. O., May 18, 1877.

BAILY, J. C., Surgeon. To report to Com'd'g General Mil. Div. Pacific and Dept. of California, for duty in Dept. of California. S. O. 106, C. S., A. G. O.

MIDDLETON, J. V. D., Surgeon. Relieved from duty in Dept. of Dakota, and ordered to Mil. Div. of the Atlantic. S. O. 106, C. S., A. G. O.

BROOKE, JNO., Asst. Surgeon. Assigned to duty at Greenville, S. C. S. O. 92, Dept. of the South, May 16, 1877.

GARDNER, W. H., Asst. Surgeon. Assigned to duty at Columbia, S. C. S. O. 92, C. S., Dept. of the South.

KINSMAN, J. H., Asst. Surgeon. Relieved from duty in Dept. of Dakota, and ordered to Dept. of the Gulf. S. O. 106, C. S., A. G. O.

DE WITT, C., Asst. Surgeon. On expiration of his present leave of absence, to report to Com'd'g General Dept. of the Platte for assignment. S. O. 106, C. S., A. G. O.

MAUS, L. M., Asst. Surgeon. Relieved from duty in Dept. of the South, and ordered to Dept. of Dakota. S. O. 106, C. S., A. G. O.

THE QUESTION OF REVISION OF THE U. S. PHARMACOPOEIA.—At a large meeting of the Society, after a free interchange of sentiment between the members, the following resolutions were adopted as offered by Dr. Nebinger:

*Resolved*, That, in the opinion of the Philadelphia County Medical Society, the propositions of Dr. Squibb to modify the *period* of revision of the United States Pharmacopœia, and other proposed reforms, are deserving of careful consideration by the medical and pharmaceutical professions.

*Resolved*, That, in the judgment of this Society, such reforms and modifications of ancient plans can be more safely entrusted to the National Convention of the Pharmacopœia and its committee of revision than to any new organization.

*Resolved*, That the action of this Society be officially transmitted to Dr. John C. Riley, President of the Pharmacopœial Convention at Washington, to Dr. Bowditch, President of the American Medical Association at Chicago, and to Dr. Squibb, of Brooklyn.

*Resolved*, That these resolutions be also published in the *Druggists' Circular*, *Chicago Pharmacist*, *Medical News*, *Philadelphia Medical Times*, *Medical and Surgical Reporter*, *The American Journal of Pharmacy*, *NEW YORK MEDICAL RECORD*, and *New Remedies*, as soon as possible.

Dr. Albert H. Smith presented the following resolutions, which were unanimously adopted:

*Resolved*, That this Society does not recognize the legal or moral right of the American Medical Association to assume the work of issuing a Pharmacopœia as proposed, nor its fitness for the work, if such right existed.

*Resolved*, That its delegates to the American Medical

Association be instructed to use every proper means, by their votes and influence, to prevent the consummation of the plan proposed by Dr. Squibb.

FRANK WOODBURY, M.D.,

Secretary.

—At a stated meeting of the New York Academy of Medicine, held May 17, 1877, the following resolution was adopted:

*Resolved*, That the New York Academy of Medicine call the attention of the American Medical Association to the defects of the present U. S. Pharmacopœia, and ask the Association either to assume the preparation and publication of the Pharmacopœia, or use its influence to secure the preparation and publication of the Pharmacopœia adapted to the wants and advances of the science of the present day.

INDIANA STATE MEDICAL SOCIETY held its annual meeting at Indianapolis, May 15th and 16th. The following officers were elected for the ensuing year: President, Dr. L. D. Waterman, Marion County; Vice-President, Dr. N. P. Howard, Hancock County; Secretary, Dr. G. V. Wollen, Marion County; Assistant Secretary, G. W. Burton.

THE AMERICAN NEUROLOGICAL ASSOCIATION will hold its third annual meeting in New York on June 6th, 7th, and 8th. The place of reunion will be announced upon the bulletins of colleges and of the Academy of Medicine, and the profession are cordially invited to assist at the sessions.

STATE MEDICAL SOCIETY OF ARKANSAS.—This Society held its regular annual meeting at Hot Springs, commencing May 1st. There was a large attendance, and numerous interesting papers were read. It would seem that the Code of Ethics regarding advertising is not observed in some quarters any more than it is in and around our own city, else the following resolution would have been entirely out of place:

*Resolved*, That information comes to this Society, from a source which cannot be contradicted, that certain practitioners in Hot Springs are in the habit of employing paid agents to drum for them at the hotels and on the various railroads of the country. This is to be deprecated by all honorable men, and we hereby declare that practitioners who employ such agents are unworthy of the confidence of the afflicted, and any unsolicited approaches, in favor of any particular physician, should be regarded as *prima facie* evidence of incompetency and unreliability, and all such should be discountenanced.

It is needless to say that the resolution was unanimously adopted. But why not bring charges against these quacks and expel them without ceremony?

The following officers were elected for the ensuing year:

President, Dr. A. N. Carrigan, Hempstead County; First Vice-President, Dr. Pollard, of Washington; Second Vice-President, Dr. A. A. Horner, of Phillips; Third Vice-President, Dr. Drake McDowell, of Hot Springs; Fourth Vice-President, Dr. J. A. Stinson, of Jackson; Secretary, Dr. R. J. Jennings, of Little Rock; Assistant Secretary, Dr. L. R. Gibson, of Little Rock; Treasurer, Dr. A. L. Breysacker, of Little Rock; Librarian, Dr. T. E. Murrell, Little Rock.

THE CORONERS' BILL OF MASSACHUSETTS.—The bill abolishing coroners in Massachusetts has passed the Legislature of that State.

EDGEWISE DISLOCATION OF PATELLA.—Dr. Blair D. Taylor, Ass't Surg. U. S. A., Fort Rice, D. T., writes: "I would like to add another case of edgewise dislocation of the patella to your collection. Mrs. —, æt. 36, wife of an officer at this post, stepped unex-

pectedly down a couple of steps, and half falling, endeavored to save herself by a violent attempt to straighten the right knee, then in a state of flexion; the result was a dislocation of the patella on its outer edge, which rested in the intercondyloid notch of the femur. I reduced it very easily by placing one hand over the joint, bending the knee as far as it would go, and then suddenly straightening it, at the same time making firm pressure with the hand on the dislocated bone. She never suffered any inconvenience from the accident in the way of locomotion, and there was no sign of inflammation or even congestion about the joint at any time subsequent to the injury."

SALICYLIC ACID IN RHEUMATISM.—Dr. S. J. Holmes writes: "I have noticed several communications in the RECORD relative to the employment of salicylic acid in the treatment of articular rheumatism, and it is corroborative evidence to me of its great value in the management of this disease.

"After its employment in a large number of cases, I have found it infallible, furnishing early in the history of each respective case complete immunity from existing symptoms, pain, heat, and swelling, and in *no* case, where the drug was employed early, have I met with the cardiac complication. In a *single* case, where it was my misfortune to be delayed in the receipt of the acid, did I get endocarditis, but am satisfied, had I resorted to it early, the patient would have escaped this complication.

"I have employed it in cases varying both in extent and intensity, and as early as the second day have found my patient free from pain and fever, with an extenuation of swelling, and upon the third or fourth day free from all swelling of joints. By its continuance for a few days I have found no propension to an immediate return of the disease.

"I am in the habit of combining it with the alkalies (usually bicarb. soda), securing thus, as an adjuvant, this reputed agent, and employing it in doses of gr. xx. three to four times per day, 'pro re nata.'

"From the success with which I have met in the employment of the 'magnum bonum,' I cannot commend it too highly, and although I have not used it in cases of erysipelas I am impressed that it will prove very efficacious in this class of cases, and shall give it a fair trial."

MONOBROMIDE OF CAMPHOR AND BROMIDE OF ZINC IN HYSTERIA.—Dr. Bourneville, who accompanied me on my visit, spoke of the various new substances which he is now trying, under the direction of Dr. Charcot, in cases of nervous disease, and especially of nitrite of amyl, bromide of camphor, bromide of sodium, and bromide of zinc. He is still very well satisfied with the effects of bromide of camphor since his first researches on the drug. It is administered largely at La Salpêtrière, in the form either of Clin's capsules or of enemata. In a great number of epileptic cases it has been found to diminish the vertigo most notably, and to diminish in a good many cases the number of fits. It has rendered considerable service in the delirium which follows the fits in epileptic mania, and has proved very useful in hysteria. I have been promised Dr. Bourneville's observations on the other drugs I have mentioned. I cannot conclude, however, without remarking that the hydropathic and bathing arrangements of such a large and special establishment as La Salpêtrière seem scanty and insufficient. This part of the hospital arrangements is so very important in the treatment of nervous affections that it is strange that the Assistance Publique does not understand the good, and even the saving, that would result from greater liberality in the supply of baths.—*Paris Cor. of Lancet.*

## Original Lectures.

## AN INTERESTING CASE OF CYANOSIS,

BEING A CLINICAL LECTURE

By WM. PEPPER, M.D.,

PROFESSOR OF CLINICAL MEDICINE IN UNIVERSITY OF PENNSYLVANIA.

(Reported by SAMUEL MILLER, M.D.)

IN a recent number of this journal, a brief mention was made of the case, which will here be discussed more fully. The diagnosis was at first attended with difficulty, owing to a want of knowledge of the previous history of the patient, who is a girl of seventeen, of small size and delicate appearance, though not emaciated or cachectic-looking. She was admitted to the University Hospital on May 7th, after having been examined by various physicians, who gave different opinions as to the nature of her case. The principal symptoms are: shortness of breath, which has been marked for the past six months, being much increased by efforts or excitement; œdema of the legs and marked enlargement of the abdomen. The eyeballs are very prominent, but there is no enlargement of the thyroid gland. The mammae are undeveloped; there is no hair on the pubes, and the menses have not yet appeared. Within the past three weeks she has had two attacks of dizziness, in which, though she did not fall, her face became purple, her hands were clenched, and she lost consciousness for an instant.

The enlargement of the abdomen being the symptom which had attracted most attention, a careful examination was first made of that part. The lower part of the trunk was enlarged and clumsy in appearance, and the lower segment of the abdomen below the umbilicus was very prominent. There was marked distention of the cutaneous veins and tenderness of the skin on pressure. On superficial percussion there was dulness over the hypogastric region, but careful percussion showed deep-seated resonance. It was evident that there was marked œdema of the abdominal walls, though the tissues were so elastic that but little pitting was caused by pressure. My colleague, Prof. Wm. Goodell, was good enough to make a careful examination of the uterus and pelvic cavity. There was no occlusion of the os uteri, the sound entering readily to the distance natural for the virgin organ. The idea of there being any retention of the menstrual fluid was thus disproved, nor was any enlargement or tumor of the uterus, or of the appendages, found. Palpation showed the presence of a small amount of free peritoneal fluid, so that it was shown that the great enlargement of the abdomen was due almost exclusively to œdema of its walls, with slight ascites. There was no enlargement of the spleen, nor any change in the size of the liver. The combination of pulmonary congestion, extensive œdema, and epileptiform attacks, suggested also the existence of organic kidney disease. A careful examination of the urine was therefore made. The quantity and appearance were normal; specific gravity, 1016; neither sugar nor albumen were present. Microscopical examination showed no tube-casts, but only some vesical epithelium and a rather large number of uric acid crystals. Besides this positive proof of the absence of kidney disease, we may add that the patient never has had hæmaturia, nor has she noticed pain over the kidneys, or frequent micturition, or any change in the appearance of the urine.

A careful examination of the thoracic organs was

next made. The chest presented no malformation; the præcordia was not prominent; the apex-beat was in the fifth interspace, nearly in the line of the left nipple; the impulse was extended, the area of dulness was slightly increased; no thrill was perceptible. There was no murmur audible at any point; the sounds were regular and distinct, with accentuation of the second sounds, especially at the pulmonary cartilage. Having thus shown the absence of any ordinary valvular disease of the heart, examination of the lungs next failed equally to give any satisfactory explanation of the symptoms. There was merely marked pulmonary congestion with bronchial catarrh.

The case was now subjected to more searching investigation. It was found that, although under ordinary conditions there seemed to be cyanosis, the least excitement was followed by a bluish lividity of the face, neck, and hands. This was also caused by exertion, and upon lying down would develop in a few moments. Even when quiet there is a faint bluish tinge of the fingers, and also a slight bulbous condition of their tips. When the circulation is disturbed there is a fulness of the superficial veins all over the body, and at all times, besides the enlargement of the veins of the abdominal walls, there is enlargement of those of the legs with bluish discoloration.

The mother, upon being specially questioned, stated that three days after the girl was born she became very blue, particularly her face, right arm, and left leg, and continued so during the first year. Afterwards she would occasionally become blue in the face, lips, and hand. These attacks occurred once or twice a week, and lasted from a few hours to a day. They gradually grew less and less frequent, and had not been noticed for a few years past. She was very weak as a baby, and could not walk at all until she was three years old. As she grew up, no signs of puberty appeared, as already mentioned. She had always had good food, had never been compelled to work, and frequently it had been necessary to give her tonics and stimulants. Her appetite had always been fair, and bowels regular. Six months ago, without any known cause, the abdomen began to enlarge, the feet swelled, the breathing grew short, and she was troubled with frequent cough. Her sleep became disturbed with startings, and grindings of the teeth. She has not lost flesh, and has had no hectic fever or night-sweats. At present her bodily temperature, as carefully tested at several points, is about one degree below normal. The above statements point unmistakably to the true nature of the case which is, I believe, one of organic cyanosis, dependent on some congenital anomaly in the structure of the heart, due to disease in intra-uterine life.

Cyanosis, or the blue disease, is to be distinguished from mere temporary lividity due to serious interference with the central circulation, as in asthmatic attacks, extensive pneumonia, etc. The term should be limited to those cases where the blue discoloration persists independently of any such acute interference with the aëration of the blood and with the circulation. So, too, the venous congestion of severe emphysema, or of distinctive valvular disease of the heart, is not to be regarded as true cyanosis, which is nearly always connected with some congenital malformation of the heart. About two hundred such cases have been recorded, and among the lesions found are illustrations of nearly every conceivable transposition and malformation of the various parts of the heart. In nearly every case, however, the lesion is such as to allow of the passage, in greater or less proportion, of blood from the right ventricle into the systemic vessels, while,

in corresponding proportion the blood from the left ventricle passes into the pulmonary circuit. In considerably more than half of all the cases, the primary lesion is a greater or less contraction of the orifice of the pulmonary artery, due to foetal endocarditis. If this be slight, and occur at a late period of cardiac development, the increased pressure in the right cavities of the heart will be able to relieve itself by some blood escaping from the right auricle through the foramen ovale into the left auricle. If the contraction be greater and occur at an earlier period before the septum between the ventricles be closed, the pressure on the right ventricle will be so great that a current of blood will be forced into the left ventricle through the imperfect septum, and a permanent opening will be maintained there. The foramen ovale also will in such cases usually be fabulous; and finally, as the left heart and aorta will thus receive an excessive amount of blood, relief will be found by a portion escaping from the over-distended aorta back into the pulmonary artery through the ductus arteriosus, which will be thus forced to remain patulous. If these various anomalies, which all proceed from the initial contraction of the pulmonary orifice, are properly adjusted to each other, it is possible that no cyanosis shall occur, despite the admixture of arterial and venous blood. But if any disturbance of circulation occurs and destroys the equilibrium, the effects of the malformation soon manifest themselves. Of course, therefore, if the lesion of the heart be such as to cause obstruction in addition, the resulting cyanosis will be more severe. Some authorities have held that the essence of cyanosis is the obstruction of the central circulation, which is evidently an error; while others have taught that the mere admixture of the venous and arterial blood is all that is required. This latter theory, though more correct than the first, does not express the whole truth. It is not mere admixture, since cyanosis may result from transposition of the aorta and pulmonary artery when no admixture occurs; but it is more strictly the admission into the systemic vessels of blood from the right heart, in greater or less proportion, and, per contra, the admission into the pulmonary vessels of blood from the left heart. But, in addition, there is certainly a profound lesion of nutrition, and quite possibly a *change in the walls of the minute capillary vessels*. This anomalous state of things exists from the period of foetal life, and exerts its injurious effects on the circulation at the time when its vessels are being developed. One of the important forces in carrying on the circulation is the normal interchange between the tissues and the blood. But we know that this cannot well occur in the systemic capillaries when the blood is but partially decarbonized; while, on the other hand, blood which is but partly venous will not properly induce the act of respiration. There must, therefore, result a refusal on the part of both systemic and pulmonary capillaries to freely transmit the blood in cyanosis; and this state of things long continued must probably result in changes in the walls and dilatation of the capillaries. The pathology and lesions of cyanosis are therefore complex, though the morbid distribution of the blood, as above defined, is the most important factor. The severity of the cyanosis and of the associated symptoms will depend on the malformation and on the interference with capillary circulation in the lungs and system. In bad cases the decoloration is intense, appears early, and persists till death. In mild cases, the cyanosis may not be perceptible to the ordinary observer, or may only appear after exertion, or excitement, as in the present case; or it even may not be present for years, till some severe disturbance

of the circulation causes it to be developed, although the congenital malformation has existed all along. Cyanosis sometimes has not appeared until the age of twenty, or even forty years. The parts of the surface where it is usually most intense are the face, the lips, the hands, the feet, and the legs. The eyes may be prominent. We must note, in addition, that the extremities of the fingers are bulbous, almost like erectile tissue; and I think this is not mere congestion, but is due to actual tissue-change, with probably changes in the capillary walls. Over the discolored area the vessels may be evidently distended. Such patients are always weakly and cannot bear exposure well, because their power of calorification is poor, and the bodily temperature is actually lower than the normal. They cannot play, or work actively, bear excitement, or make exertion. Especially are the sexual characters, so closely connected with the circulation, slowly and imperfectly developed. Respiration is imperfect, and attacks of dyspnoea frequent. The heart's action is easily disturbed. Dropsy is not so common as might be supposed. In this case it is an unusually prominent symptom. It will be noted carefully that it does not occur here only as the result of mechanical obstruction to the venous circulation, since it is not much marked in the dependent parts; but I think it rather to be explained by the same impediment to the capillary circulation from the condition of the blood and probable changes in the capillary walls. There is no special disturbance of the nervous system, the peculiar attacks described in this case being rare, and probably due to sudden cerebral congestion. Appetite and digestion may be fair, and the secretions are usually normal. The blood has not been carefully analyzed; in the present case, microscopical examination showed no change in the normal proportion of red and white globules. The life of patients with cyanosis is rarely much prolonged, few exceeding the age of twenty-one years. Death occurs from some disease, such as intense pulmonary congestion, dropsy, or, more frequently, from phthisis, resulting from progressive deprivation of nutrition.

The diagnosis of organic cyanosis connected with malformation of the heart being established, it is rarely possible to determine the precise anatomical character of the anomaly. Something may be learned from auscultation, which reveals blowing murmurs in a large proportion of cases when there are abnormal apertures in the ventricular septum, or where marked contraction of the pulmonary orifice exists. In the present case the absence of such murmur, and the comparatively mild type of the cyanosis, incline me to believe in the existence of a freely patulous foramen ovale with only moderate contraction of the pulmonary orifice. In one other of the cases which I have had the opportunity of examining, there was no murmur, and yet at the autopsy a contracted pulmonary artery and an imperfect ventricular septum were found.

It is needless to say that the treatment can only be palliative. The surface must be carefully protected and all exposure to cold be avoided. So too, much excitement and severe exertion be forbidden. Marriage is highly objectionable. Careful attention should be paid to the skin and to the state of the various secretions. Pulmonary congestion should be combated by cupping, counter-irritation, and stimulating expectorants; excessive cardiac disturbance, or failure of cardiac power, are best controlled by digitalis.

MEDICAL SOCIETY OF THE STATE OF NEW YORK.—The next meeting of the Medical Society of the State of New York will be held at Albany, June 19, 1877.—EDWARD R. HUN, Secretary.

## Original Communications.

## THE CONNECTION BETWEEN CHOREA AND ERRORS OF REFRACTION OF THE EYE.

By CHARLES S. BULL, M.D.,

SURGEON TO THE N. Y. EYE INFIRMARY AND TO CHARITY HOSPITAL.  
(Read before the N. Y. Medical Journal Association, Friday, April 6, 1877.)

A paper read before the N. Y. Academy of Medicine, June 15, 1876, entitled "Chorea: Its Cause and Treatment," the author advanced some views upon the causation of chorea which were new to the profession, and opened apparently a new field for investigation. Before accepting or rejecting a theory in medical science, the subject must be weighed carefully, and all reasons, *pro* and *con*, considered fairly. Since attending to the paper referred to, my attention has been directed to a careful examination of all the cases of chorea that I could meet with. In this work I have been very materially assisted by the kindness of professional friends, who have sent me patients suffering from chorea for examination. To these gentlemen I am greatly indebted, and especially to Dr. V. P. Gibney, of this city, to whom I take this opportunity of acknowledging my obligations. It is not my intention to discuss the subject of chorea, either in its symptomatology or pathology, as that would be a subject entirely beyond my province, nor shall I consider its etiology, except so far as it touches upon the question, whether there is any connection between chorea and anomalies of refraction, and if so, what the nature of that connection is.

The proposition formulated by the author of the paper referred to is as follows: "Chorea is a functional disturbance of the nervous system, which may give rise to organic lesions, and which arises from irritation dependent upon anomalous refraction of the eye, and, in a very large proportion of cases, to hypermetropia." The idea of the etiology of chorea entertained in this proposition is new and unexpected enough to demand a careful investigation, however such we may be inclined to question it, and in considering the subject it is first necessary to examine carefully into several points, before we can arrive at any satisfactory conclusion.

In the first place, the vision and refraction of each eye of a patient suffering from chorea should be tested separately without atropia by the test-types and ophthalmoscope; then the ciliary muscle should be completely paralyzed by atropia, and a second careful examination made, before we can reach a decided opinion as to the state of refraction. This Dr. Stevens may have done, though it is not so stated distinctly in each case.

In the second place, an error of refraction having been found to exist in one or both eyes of a chorionic patient, the proper correcting glass should be given the patient, with directions how to use it, and all other treatment directed to the chorea should be stopped; and then the effect of the glass upon the choreic symptoms should be carefully noted from time to time.

In the next place, we should carefully examine into the direct and collateral family history of the patient. Such as regards errors of refraction as well as neurotic manifestations of different kinds, with a view to the discovery of any hereditary tendency.

Finally, as supplementary to the other points, we must investigate the immediate environment of the patient, as regards food, dwellings, ventilation, poverty, and filth—in fact, everything that pertains to the hygienic surroundings. These several points I have endeavored to clear up during the past eight months, the examinations having in every case been made by myself, and the course taken by the disease carefully watched in each case. These cases are 31 in number, a detailed account of which, as well as the method and thoroughness of the examination, will now be given.

Unfortunately, very nearly all the cases included in my list belonged to the very poor class of patients, and could not afford, therefore, to purchase glasses, where such were indicated by the existence of errors of refraction. Hence the effect of the correction of anomalies of refraction upon the co-existing chorea could not be followed out, except in a very few cases, and thus our ideas, as regards one of the points to be elucidated, are left in a very unsatisfactory state.

CASE I.—A young lad, *æt.* 17. Right hemichorea for five months. Patient is under-sized, anæmic, with strumous history and cicatrices of old glandular suppuration in cervical and submaxillary regions. No rheumatism or cardiac disease. Hygienic surroundings very bad. Both parents are drunkards. One sister has Pott's disease, and a cousin is epileptic. Nothing known of grandparents.

$V = \frac{20}{xx}$ . Rejects all glasses. No insufficiency of interni. Marked hyperæmia of fundus. After atropia, *emmetropia*. Treated from June 16th to August 8th by arsenic, largest dose tolerated *grt.* xii, thrice daily, and by tonics. Discharged cured. No relapse.

CASE II.—Boy, *æt.* 8. Bilateral chorea for four years, beginning in mouth and eyelids, and gradually extending over entire body. Loud spasmodic action in larynx. No rheumatism or cardiac disease. Child anæmic, but active. Hygienic surroundings fairly good. Mother hypermetropic, and a sister squints. Maternal grandfather said to be "queer," and a maternal uncle "foolish," with occasional fits.

$V = \frac{20}{xx}$ , with manifest hyperopia of  $\frac{1}{8}$ . Insufficiency of interni of 3 for the near. After atropia, R. E. Ht.  $\frac{1}{2}$ , L. E. Ht.  $\frac{1}{6}$ . Glasses procured and worn steadily for nearly three months, without any improvement in the chorea. Subsequently cured after five weeks' administration of arsenic.

CASE III.—Girl, *æt.* 15. Bilateral chorea began in hands at nine years of age, and soon spread all over the body, being particularly noticeable in mouth and eyelids. After four months it disappeared, but returned on several occasions, and this time has lasted five weeks. Systolic murmur at apex. Hygienic surroundings fairly good. Father is a drunkard, and one brother an epileptic.

$V = \frac{20}{xx}$ . No insufficiency of interni. After atropia, *emmetropia*. After seven weeks' treatment by arsenic, iron, and cod liver oil, patient discharged cured. No return of chorea.

CASE IV.—Girl, *æt.* 11½. Bilateral chorea began, three months before I saw her, in hands, but soon spread over face, neck, and body. No trace of any neurotic tendency in any branch of family, but child always sickly, and has never recovered from an attack of scarlet fever two years ago. No rheumatism. Cardiac action irregular, but no murmur. Hygienic surroundings bad.

$V = \frac{20}{XX}$ . Insufficiency of interni of 2°. After atropia, *emmetropia*. Treated from August 1st to October 14th, 1876, by arsenic, iron, and quinine, with slow improvement, and discharged cured at latter date. No return since.

CASE V.—Boy, *et.* 14. First seen August 7, 1876. Right hemichorea since April, 1876; most marked in hands and fingers. Child anemic, strumous. A younger sister has double keratitis, with few and badly developed teeth. Hygienic surroundings miserable. Mother is myopic. No rheumatism. Systolic murmur at apex.

$V = \frac{20}{XXX}$ ; manifest H. of  $\frac{1}{4}$ . Insufficiency of interni of 4. After atropia, *hypermetropia*. Ht.  $\frac{1}{5}$ . Glasses not procured. Treated by arsenic and tonics, and discharged cured September 12th. No return since.

CASE VI.—Girl, *et.* 6. First seen Aug. 18, 1876. General chorea for seven months. Child fairly nourished, but very excitable, and has always been "nervous." Surroundings moderately good. Mother is hysterical. History of epilepsy in collateral branch of family. No rheumatism or cardiac disease. Only gained a satisfactory examination of the eyes after repeated trials.

$V = \frac{20}{XX}$ . Insufficiency of interni of 5. After atropia, *emmetropia*. Treated by arsenic for nine weeks with steady improvement, and discharged cured. No return.

CASE VII.—Girl, *et.* 11. First seen Aug. 23, 1876. Two months ago had acute rheumatism on right side, and fourteen days after recovery choreic movements began on right side, first in hand, then in leg, and finally in the face. Five years ago had meningitis. Cardiac hypertrophy and systolic murmur at apex. Surroundings fairly good. No neurotic tendency in family.

$V = \frac{20}{XX}$ . No insufficiency of interni. After atropia, *emmetropia*. Treated by arsenic and tonics for seven weeks, and discharged cured Nov. 11, 1876. No return.

CASE VIII.—Girl, *et.* 12. First seen Aug. 25, 1876. Left hemichorea began four years ago, and has lasted ever since. Most pronounced in face and fingers. The left eye has a peculiar stare. Subject to repeated attacks of phlyctenular keratitis. Child is strumous; surroundings very bad. Mother is hypermetropic. No rheumatism or cardiac symptoms.

$V = \frac{20}{L}$ . Manifest hyperopia of  $\frac{1}{5}$ . Insufficiency of interni of 4. Small macula on each cornea. After atropia, total *hypermetropia* of  $\frac{1}{30}$ . Glasses not procured. Under treatment from Aug. 25, 1876, till Nov. 21, 1876, by arsenic, galvanism, potass. iod., valerian and iron, gelseminum, ether spray, etc., but all of no avail. Discharged unimproved.

CASE IX.—Girl, *et.* 11. First seen Oct. 2, 1876. Right hemichorea since July. Occasionally squints with right eye. No history of rheumatism, but there is a systolic murmur at base. Child anemic and badly nourished. Father always had weak eyes, and died of phthisis. A brother has convergent squint.

R. E.  $V = \frac{20}{L}$ ; with cyl. + 24, axis 90°,  $V = \frac{20}{30}$

L. E.  $V = \frac{20}{L}$ ; with + 48 sph.  $\odot$  cyl. + 16, axis 90°.

$$V = \frac{20}{XXX} +.$$

After atropia, *compound hypermetropic astigmatism* in L. E. and simple hypermetropic astigmatism in R. E. Glasses procured and worn ever since, but no improvement in chorea, and child steadily running down. After three months' trial, commenced with arsenic, tonics, and cod-liver oil, and child was discharged cured Feb. 11, 1877.

CASE X.—Boy, *et.* 10. First seen Oct. 12, 1876. Perfectly well up to July 1, 1876, when he fell off a wagon and hurt his right shoulder, and ever since then the choreic movements have been present on both sides, most marked on right. Child small, but fairly nourished. Surroundings bad. Family history good, but mother had two miscarriages at eighth month before birth of patient. No cardiac symptoms.

$$R. E. V = \frac{20}{LXX}; \text{ with } + 20 V = \frac{20}{XX}$$

$$L. E. V = \frac{20}{LXX}; \text{ with } + 20 V = \frac{20}{XX} \text{ plus.}$$

Insufficiency of 4. After atropia, a total *hypermetropia* of  $\frac{1}{5}$ . Glasses not procured. Treated by arsenic, and discharged cured. No return.

CASE XI.—Boy, *et.* 11. First seen Oct. 19, 1876. Bilateral chorea set in a month ago. Child small for his age, but rather precocious mentally. No cardiac symptoms or rheumatism. Surroundings fairly good. Mother was choreic in childhood.

$V = \frac{20}{XX}$ . No insufficiency. After atropia, *emmetropia*. Treated by arsenic and cod-liver oil, and discharged in five weeks cured. No return.

CASE XII.—Boy, *et.* 11. First seen Oct. 24, 1876. On Aug. 26, 1876, child began to complain of pain in arms and legs, and on the next day was completely paralyzed in both upper and lower extremities. Remained in this condition for eight months, and then began to get the use of his arms. As recovery advanced, bilateral chorea developed itself, and has been well-marked for two months. No cardiac symptom.

$V = \frac{20}{XX}$ . No insufficiency. After atropia, *emmetropia*. Maternal grandmother has purpura hemorrhagica, and a maternal aunt is epileptic, following puerperal convulsions. Treatment by arsenic procured, but child could not attend. Has since recovered.

CASE XIII.—Girl, *et.* 6. First seen Oct. 26, 1876. Child is strumous, and has cicatrices in cervical and submaxillary regions, with tendency to phlyctenular conjunctivitis. Two years ago had measles, and since then health bad and nutrition very much disturbed. General chorea came on in March. Has a brotli with infantile paralysis. Surroundings bad.

$V = \frac{20}{XL}$ . Faint corneal macula. No insufficiency interni. After atropia, *emmetropia*. Treated by arsenic and tonics, and discharged Dec. 15, 1876, cured. No return.

CASE XIV.—Boy, *et.* 7. First seen Oct. 31, 1876. Well-marked bilateral chorea since infancy. Child has Pott's disease of lower dorsal region, and has worn a brace for a year. Child strumous and nutrition bad. No cardiac symptoms. No neurotic tendency in family, but surroundings bad.

$V = \frac{20}{XXX}$ . Insufficiency of interni of 2. After atropia, *emmetropia*. Treated by tonics, cod-liver oil, and arsenic for six weeks, but with no result. Spine sprayed with ether for two weeks, but without effect.

CASE XV.—Boy, *æ*t. 9½. First seen Nov. 9, 1876. Child is a ruddy, healthy Irish boy, who has never been ill since an attack of measles four years ago. Left hemichorea came on four weeks ago. No cardiac disease or rheumatism. No neurotic tendency in family. Hygienic surroundings good.

$V = \frac{20}{XX}$ . No insufficiency of interni. After atropia, *emmetropia*. Treated by arsenic, but child eloped before treatment was concluded.

CASE XVI.—Boy, *æ*t. 10. First seen Nov. 14, 1876. General chorea began two years ago. Child small and poorly nourished. No cardiac disease. Surroundings the worst possible. Father a drunkard. No neurotic taint in family.

$V = \frac{20}{XX}$ . Insufficiency of interni of 2°. After atropia, *emmetropia*. Cured by arsenic in three weeks, but chorea returned in face in February. Again cured in four weeks.

CASE XVII.—Girl, *æ*t. 6. First seen Nov. 28, 1876. Child healthy. Bilateral chorea for two months. One brother hypermetropic, also mother. No neurotic taint or cardiac symptoms.

$V = \frac{20}{XX}$ . Insufficiency of 7°. After atropia, R. E. *hypermetropia*  $\frac{2}{10}$ ; L. E. *emmetropia*. Glasses not procured. Cured by arsenic in five weeks. No return.

CASE XVIII.—Boy, *æ*t. 10½. First seen Dec. 10, 1876. Left hemichorea for three weeks. Patient always delicate and nervous. Systolic murmur at apex. Troubled with ascariides. No family neurotic taint. Surroundings bad.

$V = \frac{20}{XX}$ . Insufficiency of 8°. After atropia, *simple hypermetropic astigmatism*  $\frac{1}{10}$ . Glasses not procured. Treated by arsenic and tonics and santonin, and cured in five weeks.

CASE XIX.—Girl, *æ*t. 8. First seen Dec. 12, 1876. Left hemichorea since April, from which she at one time recovered, but it relapsed five weeks ago. No cardiac. Great poverty. Child small and feeble.

$V = \frac{20}{XXX}$ . No insufficiency. After atropia, *emmetropia*. Treated with marked improvement by arsenic and tonics.

CASE XX.—Girl, *æ*t. 14. First seen Dec. 21, 1876. Right hemichorea for six weeks. Anæmic and strumous. No cardiac, but precocious and excitable. Surroundings fairly good. Menses appeared once four months ago, but have not returned.

$V = \frac{20}{LXX}$ ; with + 40,  $V = \frac{20}{XXX}$ . Insufficiency of 7°. After atropia, a total *hypermetropia* of  $\frac{1}{30}$ . Glasses not procured. Treated by arsenic and cured in two months.

CASE XXI.—Girl, *æ*t. 9½. First seen Dec. 28, 1876. Right hemichorea for three months. Subject to lumbricoid worms. No neurotic taint in family. No cardiac symptoms.

$V = \frac{20}{XX}$ . Insufficiency of 8°. After atropia, *emmetropia*. Treated by santonin without result. Cured by arsenic in four weeks.

CASE XXII.—Girl, *æ*t. 16. First seen Jan. 9, 1877.

Had typhoid fever three years ago, followed by right hemichorea, which lasted several months, and then attacked left side. No cardiac symptoms or rheumatism. Mother is hysterical. Father died of rheumatism.

$V = \frac{20}{XXX}$ . Insufficiency of 3. After atropia, total *hypermetropia* of  $\frac{1}{10}$ . Glasses not procured. Treated by arsenic, and cured in six weeks. No return.

CASE XXIII.—Girl, *æ*t. 10. First seen Jan. 11, 1877. Left hemichorea for two years. Slight lateral curvature of spine. Systolic murmur at apex. Surroundings good. Mother hypermetropic.

$V = \frac{20}{XX}$ . Insufficiency of 9°. After atropia, total *hypermetropia*, R. E.  $\frac{1}{10}$ ; L. E.  $\frac{1}{4}$ . Glasses not procured. Cured by arsenic in six weeks. No return.

CASE XXIV.—Girl, *æ*t. 9. First seen Jan. 16, 1877. Bilateral chorea ever since early childhood. Three other members of the family choreic. Surroundings good. One of nine children.

$V = \frac{20}{XX}$ . Insufficiency of 6°. After atropia, R. E. *emmetropia*; L. E. *hypermetropia*  $\frac{1}{5}$ . Glasses procured and worn for two months and a half, without improvement in chorea. Since then chorea has nearly disappeared under arsenic and tonics.

CASE XXV.—Boy, *æ*t. 6. First seen Jan. 16, 1877. General chorea for four years; brother of preceding case. Boy healthy and well developed.

$V = \frac{20}{XX}$ . No insufficiency. After atropia, R. E. *compound hypermetropic astigmatism*; L. E. *simple hypermetropia*. Glasses not procured. Marked improvement under arsenic.

CASE XXVI.—Woman, *æ*t. 24. First seen Jan. 20, 1877. Had whooping-cough at six years of age, and unilateral chorea, not well-marked, ever since. Spinal irritation for last six years. Asthenopia of late. Anæmic systolic murmur at base. Sister of preceding.

$V = \frac{20}{L}$ . Insufficiency of 3°. After atropia, total *hypermetropia* of  $\frac{1}{4}$ .  $V = \frac{20}{XX}$ . Glasses procured and worn faithfully, but no change in the chorea.

CASE XXVII.—Boy, *æ*t. 3½. First seen Jan. 23, 1877. Pott's disease of lower dorsal region for two years. Right hemichorea for last two weeks. Rheumatism in family. Had whooping-cough when two years old. Vision cannot be measured owing to youth of patient. After atropia, *emmetropia*, though examination somewhat difficult, owing to restlessness. Cured by arsenic in four weeks.

CASE XXVIII.—Boy, *æ*t. 17. First seen Jan. 23, 1877. Left hemichorea for two weeks; tall, thin and anæmic; surroundings bad. No cardiac symptoms or rheumatism. No neurotic taint in family.

$V = \frac{20}{XX}$ . Insufficiency of 6°. After atropia, *compound hypermetropic astigmatism*. Glasses not procured. Marked improvement in ten days from use of arsenic. Patient then disappeared.

CASE XXIX.—Boy, *æ*t. 11. First seen Jan. 30, 1877. Two years ago had diphtheria, and ever since bilateral chorea. Attacks of transient amblyopia, with rapid nystagmus. On Feb. 20th had an epileptiform fit.

$V = \frac{20}{XXX}$ . Insufficiency of 8°. After atropia, *emmetropia*.

*tropia*. Passed a long lumbricoid after a dose of sanftin, and since then chorea much improved.

CASE XXX.—March 6, 1877. Boy, *et.* 8. General chorea for four years. Child ill-developed, physically and mentally. One of twins, the other being sound in all respects. Mother has five other children, all healthy. Patient has double-scrotal hernia. Moderate exophthalmus, and eyes are set in a "stare." Teeth notched, and badly developed. No history of syphilis in mother, but father has not been examined. Vision probably normal, but child does not know his letters. After atropia, ophthalmoscope shows hypermetropia  $\frac{1}{2}$  oc. utr.

*It.*  $\frac{1}{8}$ . Mother declined to purchase glasses for child.

Tonics, cod-liver oil, internally and externally, and arsenic ad. gtt. vii., with marked improvement in general health and chorea in course of three weeks.

CASE XXXI.—March 8, 1877. Boy, *et.* 14. General chorea for past four months. Child well developed, but not very bright intellectually. Mother hypermetropic. One sister has convergent squint. A maternal uncle is epileptic, and father is crippled with rheumatism, and has cardiac disease. No history of rheumatism, and no cardiac murmur in patient.

$V = \frac{20}{L}$ ; with  $+\frac{1}{20}$   $V = \frac{20}{XX}$ . Insufficiency of 6. After

atropia,  $\frac{20}{LXX} +$  and with  $+6 = \frac{20}{XXX} +$ .

*It.*  $\frac{1}{8}$  circa by ophthalmoscope; convex six spherical ordered and worn by boy for nearly a month, but as yet no improvement in chorea. This child since cured by arsenic.

In analyzing these thirty-one cases, we find that fifteen (15) of them are emmetropic. Two are cases of emmetropia in one eye and hypermetropia in the other. Eight are cases of simple hypermetropia of the same degree in both eyes. Two are cases of unequal degrees of hypermetropia in the two eyes. Two are cases of simple hypermetropic astigmatism of the same degree in the two eyes. One is a case of hypermetropia in one eye and simple hypermetropic astigmatism in the other. And finally we have one case of simple hypermetropic astigmatism in one eye and compound hypermetropic astigmatism in the other. So much for the state of the refraction.

Of these sixteen cases of hypermetropia only five could be induced to purchase and wear the necessary correcting glass, that is, not quite one-third of the number. In none of the five was there any improvement in the chorea, brought about by the use of the glasses, for several months.

Of the thirty-one patients, sixteen were males, and fifteen females, being about equally divided, which does not accord with the usual statistics of chorea, as it is stated that the disease is more common among females than among males.

The ages varied from three and half years to twenty-four years, and the duration of the disease ranged from two weeks to eighteen years.

The choreic movements were bilateral in eighteen cases; there was right hemichorea in seven cases, and left hemichorea in six cases.

In twenty-four cases the hygienic surroundings of the patients were bad, the families living in crowded tenements, with bad food, and worse ventilation, and in many of them one or both parents were addicted to drink.

Among the sixteen cases of errors of refraction there were nine in which one or more members of the family

were hypermetropic. In nine cases there were one or more members of the family who manifested other neuroses, such as idiocy, epilepsy, or hysteria. Signs of past or present struma were met with in nine cases, and congenital syphilis in two cases. Pott's disease of the spine existed in three cases.

Four members of one family were choreic. In ten cases there was valvular disease of the heart, with history of rheumatism in patient as well as in other members of the family. In three cases the patients had passed worms.

The family tendency to neurotic taint is well shown in the Martin family, here given:

1. Daughter, 24. H.  $\frac{1}{4}$ . Modified chorea.
2. " 23. Em. No chorea, but hysteria.
3. Son (died an infant).
4. Daughter, 19. Hypertrophy and valvular disease, rheumatic. Em. No chorea.
5. Daughter, 15. Valvular dis., rheumatic. No chorea.
6. Daughter, 12. Em. No chorea.
7. " 9. H. and chorea.
8. Son, 6. H. and chorea.
9. Daughter, 4. Em. No chorea.
- Mother, 44. H. + Presbyopia.

In the course of the examinations into the possible causes of chorea in these cases, the subject of consanguineous marriage was considered, as this has been alleged as a cause, but in none of the cases was there any blood relationship between the parents. Huth, in his work on *Consanguineous Marriage*, speaks of the extreme frequency of cardiac complication with chorea, and says that out of 104 cases of chorea examined, fifteen only were free from cardiac murmur and signs of rheumatism. This is a larger proportion than I met with.

In only one case among the thirty-one could I find no cause for the onset of the chorea, whether in family taint, hereditary tendency, hygienic surroundings, or sudden fright. Another point which I would like to call attention to here is the condition of the external muscles of the eye. If anomalous refraction is to be regarded as one of the causes of chorea, if not the cause, surely as much importance should be laid upon insufficiency of the internal or external straight muscles of the eye. There was an insufficiency of the internal rectus muscle in all the sixteen cases of chorea in which refractive errors were found to exist, but also in seven out of the fifteen cases of emmetropia and chorea. None of the patients had ever complained of diplopia, and yet insufficiency of the internal recti is a very prominent cause for asthenopic symptoms; and, if so, why not rank chorea among them?

In view of the histories of these patients, we certainly cannot regard the etiology of chorea as uncertain or obscure, whatever may be said of its pathology. Many of these cases point unquestionably to the influence of hereditary predisposition, if not to the chorea, at least to a neurotic taint, and the question of the mutual transformation of diatheses is too prominent a one in general pathology to doubt its probability. In not a few of the cases cited the chorea may, I think, be regarded as the manifestation of a neurotic taint, which appeared in other forms in the direct or collateral ancestors of the patients. The only conclusion possible, after studying the cases, is that, while the coexistence of anomalies of refraction with chorea may be something more than coincidental, yet they cannot be regarded as a predisposing cause to chorea. It is perhaps possible, I do not say probable, in view of the many asthenopic symptoms occasioned by uncor-

rected hypermetropia, that in a patient of weak constitution, bad health, or with unfavorable hygienic surroundings, or belonging to a family where other neuroses exist, hypermetropia or astigmatism may act as an exciting cause to choreic manifestations; but so may almost anything else in such a case. That there is no such connection of cause and effect as Dr. Stevens affirms to exist has, I think, been satisfactorily proven by the cases just cited.

A recent review of the Transactions of the N. Y. Academy of Medicine, which appeared in the *American Journal of the Medical Sciences* for April, 1877, presents the subject in its proper light, and I may therefore be pardoned for quoting it:

"How refreshing it is to the physician, who has been worrying over capillary embolism of the corpus striatum, heredity, or rheumatic diathesis, to find that the trouble is only 'anomalous refraction' after all, and the remedy is 'glasses.' At any rate, his course is clear. When he has a perverse case of chorea, he does his whole duty in the matter by giving the patient a note to the nearest eye-doctor, who then becomes responsible for the cure. So the physician is satisfied, the oculist is satisfied, and the patient is, or ought to be, satisfied; if he does not get well, he can only blame himself. But when the doctor is alone, he has a lurking suspicion that he has heard of cases of chorea which have been cured by iron—not spectacles, but bromide of iron—cinicifuga, arsenic, and tonics, and which became completely well without having their eyes 'corrected.' He also recalls the very favorable results reported by Drs. Gray and Tuckwell (*Lancet*, Nov. 28, 1876, and *Monthly Abstract of Med. Science*, Feb., 1877, p. 58), from the purely expectant plan of treatment, without any aid from medical or surgical therapeutics whatever; and, as it has been asserted on good authority that it is rare, even among what are considered healthy eyes, to find one which does not exhibit some anomaly of refraction, this complication may prove to be, after all, rather a coincidence than a cause of chorea."

47 EAST TWENTY-THIRD STREET.

## THE SO-CALLED MILK FEVER AND ANTISEPTIC MIDWIFERY.

By BLAIR D. TAYLOR, M.D.,

ASSISTANT SURGEON, U.S.A., FORT RICE, D. T.

HAVING seen several articles recently published in this journal bearing upon the use of antiseptics after labor, I am prompted to give my experience for several years past, which coincides closely with the opinions held in the above-mentioned publications.

In ordinary cases of midwifery where no preventive is used, in from forty-eight to sixty hours after labor, at the time when the breasts begin to swell with milk, the pulse quickens, the temperature rises, there is headache and sweating, and often this combination of symptoms is ushered in by a chill, which is sometimes repeated.

Previous to the revolution in my ideas on this subject, I always expected these symptoms and looked upon them as the "milk fever," due to the rapid secretion of the lacteal fluid. I soon began to notice, however, that the train of symptoms just mentioned never commenced until after the discharge from the uterus had become decomposed and offensive, and when it struck me that the chill, fever, sweating, bore a strong resemblance to the symptoms of septicæmia and those of pyæmia developed in surgical cases.

Acting upon this thought, I began the use of antiseptics—mode and manner soon to be described. Since then I have never seen in any case of obstetrics the symptoms of the so-called "milk fever," whether the secretion of milk was abundant or otherwise.

I will review briefly the *septic state* of the uterus after labor, to show that the absorption of a certain amount of septic material is a *necessity* unless prevented by proper measures. In the first place, there is the denuded surface, once covered by the placenta, meshed with large vessels and presenting every facility for absorption possessed by an open wound; secondly, the rest of the mucous membrane of the uterine cavity, being in the act of renewal and abnormally vascular, might easily absorb septic fluids; thirdly, the lymphatic system, so liable to be involved in pyæmic processes, is hypertrophied in the impregnated uterus; lastly, the remains of membranes and clots of blood beginning to decompose, can furnish a large amount of septicæmic matter for several days. Surely no one can be surprised that blood-poisoning should occur under such favorable conditions, or rather he should be astonished if it did not. On the other hand, why should the natural secretion of milk give rise to chill, fever, sweating, and general constitutional disturbance any more than the secretion of the urine or the bile. I can see no reason for the name "milk fever," except that as the fever comes on the third day and the milk does the same—"post hoc, ergo propter hoc." But, as it happens, the decomposition begins at the same time, a much more adequate cause to account for the symptoms.

My mode of procedure after labor is this: In five or six hours after the placenta has been delivered I slip a bed-pan under the woman and inject into the vagina, with a Davidson's syringe, a quart or a quart and a half of warm water containing two or three per cent. of carbolic acid, or, if the lady objects to the odor, an equivalent proportion of salicylic acid; the water washes out the vagina thoroughly and disinfects all clots remaining there. Repeat this *twice* a day for four days, then *once* for three more days, when it is no longer needed. There will be no odor to the discharge, nor will there be a symptom of fever, no matter how much milk there may be. I have never seen this treatment fail, and could multiply cases, but will give one in which the danger of septicæmia was much greater than in any ordinary case of labor. I transcribe my notes made at the time:

"March 23, 1876; Mrs. M., æt. 36; wife of an officer; fourth child. Boy, æt. seven months, first stage twenty-four hours. *Forceps*. The os was extraordinarily thick and rigid, nodulated by chronic inflammation of the cervix—in fact, was like a rigid tube; would not dilate by any means of softening beyond the size of a silver dollar. (I had no Barnes dilator.) Breech presented, but head brought down by conjoined manipulation. Labor powerless, no pains of account. Second stage, six hours. Forceps applied *above the superior strait* with difficulty, owing to the small size and rigidity of the os, which had to be incised. Child born dead; delivered in twenty minutes with forceps."

It would seem that a case like this, presenting an aggravation of all the usual conditions present after labor, would be unusually likely to be followed by constitutional irritation; but, notwithstanding her milk was abundant, she never had a temperature above 99°, owing to the use of carbolic acid as above indicated, and on the twelfth day she was walking about the house without having had a bad symptom. I could cite one or two other forceps cases with simi-

lar results, but there were none so bad as this, so that it is hardly necessary. I may say, in conclusion, that I have followed the antiseptic plan in obstetric cases for nearly four years, and have never known a woman to have fever upon whom it was employed. I prefer carbolic to salicylic acid, because of its greater volatility, thereby penetrating into the cavity of the uterus and disinfecting the parts more thoroughly.

## Progress of Medical Science.

**RECOVERY FROM SARCOMA.**—Dr. S. Almström relates the remarkable case of a young man, 22 years of age, who presented himself at the hospital in Upsala with the following history:—About six years previously he noticed a very small tumor behind the angle of the lower jaw. The tumor was hard, not sensitive, and was readily movable. Its growth was slow, and caused but little inconvenience. Within a year, when it had become as large as a hen's egg, it began to increase with greater rapidity, and the general condition of the patient became bad. Symptoms of hyperæmia of the brain supervened; he was often troubled with headache and delirium, and occasional syncope after severe exertion. There was loss of appetite and emaciation, especially during the previous two or three months.

On examination, a tumor, about the size of a man's fist, was seen on the right side of the neck, extending from the ear as far as the supraclavicular fossa. The larynx was slightly displaced to the left, but quite free from attachments to the tumor. The latter was quite firm, and its surface nodular; it was immovable and apparently attached to the skin. Pressure caused but little pain. The external jugular vein, passing over the tumor, was considerably enlarged. The sterno-cleido-mastoid appeared to be included in the tumor. The right tonsil was displaced towards the median line, and very much swollen. No enlarged lymphatic glands were discovered. It was impossible to detect the point from which the tumor had its origin. The diagnosis of sarcoma was made, and an operation for its removal attempted. It was discovered, during the operation, that the attachments of the growth to the deeper parts were too extensive to admit of the successful completion of the operation, and it was therefore discontinued. A small portion only of the tumor was removed for microscopic examination. The wound was closed with sutures and Lister's method employed. There was but little reaction, and the patient made a good recovery. The subsequent suppuration was very inconsiderable, and the tumor gradually decreased in size. Every day the circumference of the neck, measured over the tumor, decreased nearly a centimetre. The general health of the patient improved, the appetite became good, the brain symptoms disappeared, and did not return even during severe bodily exertion. Six weeks after the operation, when the patient left the hospital, there was but little trace of the tumor to be discovered. The right tonsil had resumed its normal position, and was much smaller. The movements of the jaw were free, and there was no difficulty in swallowing. The case, if one of true sarcoma, is a very rare one, and has considerable therapeutical importance.—*Upsala Läkare-förening's Förhandl.*, Vol. 12, No. 2.

A NEW AND SIMPLE METHOD FOR THE REMOVAL OF

**LARYNGEAL POLYPI.**—The *Monatschrift für Ohren-Heilkunde* of 1877, contains the description of a new procedure by Voltolini, by which he manages to remove intra-laryngeal growths without either special instruments or a mirror. He simply swabs out the larynx, and in so doing tears off the soft polypi. The swab consists of a flexible wire, to which is attached a sponge whose diameter does not exceed, at the utmost, one millimetre. The sponge, having previously been softened in water and then pressed out, is introduced "blindly" into the larynx, which closes upon it. No attempt should then be made to advance or press downwards until the larynx opens again. If this takes place, as is very often the case, then the swab must be passed up and down between the vocal cords. In favorable cases, when the sponge is withdrawn the polypi will be torn off. The method is only applicable to comparatively soft growths. It is thought that after the diagnosis has once been made any practitioner may be able to do the operation successfully. Voltolini gives six cases in which this simple method was pursued.—*Berl. Klin. Woch.*, 18, 1877.

**THE PROPHYLACTIC TREATMENT OF PLACENTA PRÆVIA.**—Prof. T. Gaillard Thomas states that we have by no means reached a point in the treatment of this alarming complication of labor, where we may feel sure that we have at our disposal means to ward off the danger of death from either mother or child with any certainty, while skilful management may accomplish a great deal. In many instances the services of the practitioner are not attainable, and a fatal loss of blood may occur, or the mother, from repeated hemorrhages, is apt to come to her labor sanguinated and exhausted both in mind and body. As the only remedy, the induction of premature delivery is recommended after the viability of the child is established. As for the objection that a child who has had less than nine months of intra-uterine existence has not as good a prospect of life as one that has arrived at full term, it is urged that such would have a brighter prospect when dependent upon pulmonary respiration for the aëration of its blood than upon a crippled and bleeding placenta. For the mother the safety would be doubtless greater. Dr. Thomas believes that when premature delivery becomes the recognized and universal practice for placenta prævia the statistics of the present day will be replaced by others of a far more satisfactory kind. Eleven cases are adduced in support of this position of living children being delivered, all of the mothers, with one exception, eventually recovering, while, according to the statistics of Sir James Simpson, based upon the analysis of 399 cases, one-third of the mothers and over one-half the children were supposed to be lost, and Read computed the mortality as one in four and a half mothers, while the large majority of the children were lost.—*American Practitioner*, March, 1877.

**DEMONSTRATION IN HONOR OF PROFESSOR P. J. VAN BENEDEK.**—A number of the old students of the illustrious professor of Louvain have set on foot a demonstration to mark their appreciation of the eminent services he has rendered to the cause of education and to science during the last forty years. The majority of the medical men in Belgium should take part in this demonstration. It will consist in the presentation to him of his own bust in marble, executed by the sculptor Fraikin. The presentation will take place in the latter half of the present month. It will be followed by a banquet.

# THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

## THE DANGERS OF CHLOROFORM.

THE trial of the Railway dentist for causing the death of Walter E. Lewis with chloroform has attracted a great deal of attention, not only on the part of the public, but of the profession. As will be remembered, last January the boy, shortly after having eaten a hearty supper, called upon the dentist for the purpose of having a tooth extracted. Chloroform (slightly mixed with ether) was administered while the patient was sitting in a chair. After a few inhalations with the napkin close to the face, the pulse began to flag, when the tooth was hurriedly extracted. The child's head then rolled to one side, and respiration ceased. The patient was left in the chair for several moments without any attempt at resuscitation, and until a neighboring physician arrived. Attempts at artificial respiration were then made, the galvanic battery applied, and all the other means usually employed on such occasions, but to no purpose.

The post-mortem examination revealed all the organs in a healthy condition. The heart was free from fatty degeneration, and was flabby; the right side contained a small quantity (half an ounce) of dark fluid blood, while the left side was entirely empty. The blood was dark and fluid. As far as could be judged from the autopsical lesions, the victim was in good health at the time of the accident. The coroner's jury brought in a verdict against the dentist, charging him with gross carelessness in the administration of the anæsthetic. The Grand Jury sustained the charge, and the case was regularly tried in the court of Oyer and Terminer. The charge was manslaughter.

The prosecution endeavored to prove that the defendant did not use the ordinary precautions in giving the anæsthetic; that he was intoxicated at the time; that not a sufficient amount of air was allowed, and that the death was directly caused by such acts of carelessness. It was shown that the child had a full stomach at the time of taking the anæsthetic, that

neither the pulse nor the respiration was watched during the administration, that the tooth was drawn when the patient was in a dangerous condition, and that the patient was left in the chair after the accident for several minutes without help.

As might have been anticipated, the charge of drunkenness could not be satisfactorily sustained. The experts for the prosecution stated that it was improper to administer chloroform while the patient had a full stomach, or was in a sitting posture; that it was always the rule to examine the chest organs; and, in cases of doubt, the stomach; that a full stomach and the upright position invited accident; that a failure of the pulse and respiration demanded an immediate resort to artificial respiration.

The main argument of the defence was based upon the fact that death not infrequently occurs during the different stages of anæsthesia without any apparent cause, without any better explanation than that afforded by the vague term, *idiosyncrasy*. It was also proved that the defendant was quite accustomed to give chloroform, and that he administered it in the usual manner for dental operations.

The judge in delivering his charge stated that, the burden of proof resting upon the State, the benefit of a doubt belonged to the defendant. Reciting the well-known aphorism that a practitioner is only expected to exercise ordinary skill in the practice of his profession, the question was one of degree rather than kind, and was, under the circumstances, to be settled by the jury. The ruling was to the effect that a practitioner was not accountable for the death of a patient which death might have been prevented by extraordinary skill on the part of another. This was the charitable construction which the law placed upon the want of skill possessed by the prisoner. Why this should apply in the case of so dangerous an article as chloroform does not appear, more especially when it was used contrary to the rules laid down by authority.

Although it could not be proved that death from chloroform was produced as the direct result of carelessness, the presumptive evidence of such a fact was very strong. A full stomach is not of itself a cause of death in chloroform, although few medical men would be willing to run the risk of its influence as an impediment to the action of the lungs or heart, especially when the patient is in an upright position. The impaction of vomited material in the trachea is another element of danger; but as no such accident occurred in this case, the consideration of its possibility, was, for obvious reasons, not allowed. The law can really hold no one accountable for accidents which might have occurred from negligence. There must be a direct association between cause and effect. If the patient in question had died by suffocation as the result of food in the trachea, the full stomach would have been a more important factor in the case. The absence of any positive proof that the posture, full

stomach, rapidity of administration, deficiency of atmospheric air, individually or collectively, had any positive and direct effect in producing death in this case, gave the defence a wide latitude for instilling doubt in the minds of the jury. The opinion of the medical experts was to the effect that the chloroform was carelessly administered, and that the fatal issue was thereby invited. By an oversight on the part of the prosecution, there was very little stress laid upon the neglect to revive the boy the moment the signs of danger appeared. Instead of attempting this the dentist ran for help, and when help arrived several minutes afterwards, the child was still upright in the chair. This at least does not prove the exercise of even ordinary skill in cases of danger. There was a reasonable chance that the child might have been saved if resuscitation had been resorted to at once. It is impossible to say how many lives might be sacrificed during anesthesia, if every one followed the practice of the Rahway dentist.

The neglect to place the child in the recumbent position as soon as danger appeared, was the strongest point against the prisoner. There does not appear to be the slightest excuse for it. No one has a right to use an agent known to be treacherous and dangerous unless he is competent to exercise requisite skill in counteracting bad effects when they show themselves. If the dentist possessed such skill, he did not use it. Whatever may be said of the other circumstances of the case, the omission to perform so obvious a duty as placing the boy in a proper position immediately after the accident, and resorting to the ordinary means for overcoming asphyxia, syncope, etc., amounts, professionally speaking, to criminal neglect. But, as we before remarked, very little notice was taken of this, and the defendant was acquitted.

The result of the trial does not help to establish any new principle in regard to the administration of chloroform in dental practice. Notwithstanding, twelve intelligent men in New Jersey have decided that no fault can be found with the administration in this case, the profession at large will still hold to its settled opinions, and still lean to the safe side, declining to follow so questionable an example.

#### THE AMERICAN MEDICAL ASSOCIATION.

THE American Medical Association will hold its next annual meeting the coming week in Chicago. Within the past few years it has so far redeemed its reputation as a useful, orderly, and influential medical society, that it commands the respect and sympathies of the entire profession of the country. The plan of its present organization, the systematic division of its labors, both executive and scientific, are as near perfection as can be expected, and are well calculated to develop the working element of its members. It is to be regretted, however, that such labors are not more

widely distributed and that the individual workers are not more numerous. Time, however, will probably remedy this. With certain gentlemen the association is used as a convenient advertisement for their intellectual wares, and no session passes without some contribution from them. If some second-hand papers thus find their way into the transactions it is hardly surprising. But this evil is beginning to grow less and less, and may in the end entirely disappear.

There is no doubt that the committee in Chicago will make all suitable arrangements for the convenience and comfort of the members in attendance. The hall selected for the meeting is commodious and will serve its purpose, while the rooms for Sections will be equally convenient and suitable.

The addresses to be delivered in open session, judging from the reputation of the gentlemen chosen to deliver them, will be fully equal in value and interest to any of those of previous years. The question of the revision of the U. S. Pharmacopœia will force itself before the Association for discussion. The verdict regarding the proper course to pursue can hardly be doubted. We have on former occasions expressed our opinion so strongly in favor of the advisability of a change that it is unnecessary to repeat it now. It is to be hoped that the different delegates who are charged with instructions to vote upon the measure will do so, understanding the responsibilities they assume and the important professional interests which they represent. Aside from the general subjects which may be presented under the rule, the scientific interest of the meeting will centre around the different Sections. The experiences of the International Medical Congress last year should not be lost upon the committee of the different Sections who arrange the subjects for discussion. The trouble has hitherto been that too little time has been allowed for arranging the order in which the papers should be read, and no opportunity has been given to members who might wish to participate in any discussion to prepare themselves beforehand. We wish it could be arranged by the gentlemen having such matters in charge to publish the lists of subjects in advance, as was done by the managers of the Medical Congress in Philadelphia, and still more recently by the president of our own State Society. We have no doubt that a well-digested plan having such end in view would meet with general satisfaction, and advance the interest of the association.

#### MEDICAL MATTERS IN NEW JERSEY.

NEW JERSEY seems to have done good service at its capital last week, both in a medical and sanitary way. Under a recent law for the organization of a State Board of Health, to consist of the Secretary of State, the Attorney-General, and seven other citizens of New Jersey, Governor Beadle assembled the Board at the State House on the 23d. The plan of work, as laid

out by the Board, shows an earnest intent to look after the sanitary welfare of the State. Dr. E. M. Hunt, as the Secretary, superintends the work under the direction of the Board, which has in it a good share of members from the medical profession. The bill, while it gives no compulsory authority, will enable the Board to make needed investigation at present, and provides for the necessary running expenses within reasonable limits.

The New Jersey State Medical Society met on the evening of the same day. As there are no medical colleges in New Jersey, the proceedings do not abound with voluntary contributions. The President and third Vice-President are required to give an address or paper, and an essayist is always appointed on a subject assigned. These papers are generally good, and often, like that of Dr. Marsh, this year, on "Autumnal Catarrh," are of permanent value. A leading feature of this Society is a condensed report from its Standing Committee, which seeks, from the returns of the reporters for each county, to give a medical history of the State for the year. This is ably done, and to it, in the Transactions, all such clinical reports or papers that are sent by the county societies and approved by the committee are appended. As a result, the Transactions are not surpassed by those of any State save our own. From them, for the last ten years, can be selected some most valuable papers. We commend this mode of condensation to other similar societies, and shall more fully notice the Transactions of the year when published.

#### THE CONNECTICUT STATE MEDICAL SOCIETY.

THE Annual Meeting of the Medical Society of Connecticut took place in Hartford, May 24th and 25th. The attendance was good and the usual amount of interest was manifested in the proceedings. As will be seen in our report, a number and variety of topics were discussed. The question of the revision of the Pharmacopœia was not lost sight of. Although nothing was suggested in an authoritative way, the drift of opinion is quite apparent.

The failure to secure the passage of a bill creating a State Board of Health, is not an unusual circumstance under similar conditions, but the explanation of its failure is certainly unique in the annals of medical legislation. The Committee make the following significant statement in their report:

"It was reserved for the Speaker of the House of Representatives to discover and announce to the world, as principles of government, that it is *not* the province of the State to take measures to protect health or prevent disease, and that if any body of men possessed knowledge, training, and skill, which fitted them alone to perform any services, however beneficial to the State, it was impossible for the State to avail itself of these services, as thereby an unfair

discrimination would be made against the ignorant and illiterate."

It is scarcely a wonder that a legislative body, who could not be insulted by such an argument, should vote against the bill.

## Reports of Societies.

### MEDICAL SOCIETY OF NEW JERSEY.

*One Hundred and Eleventh Meeting, May 22d and 23d, 1877.*

DR. J. W. SCHENCK, OF CAMDEN, PRESIDENT, IN  
THE CHAIR.

(Special Report for the MEDICAL RECORD.)

THIS Society held its One Hundred and Eleventh Annual Meeting in Trenton, on Tuesday and Wednesday, May 22d and 23d. The President, Dr. J. W. Schenck, of Camden, presided. All the District Societies in the State were well represented excepting Sussex. There were also present delegates from the State Medical Societies of Maine, New York, and Pennsylvania.

The meeting was called to order at eight o'clock on Tuesday evening, and the Rt. Rev. John Scarborough, Bishop of New Jersey, read a portion of the Psalms and offered prayer.

After the transaction of the regular routine business, the remainder of the evening was devoted to the reading of the annual address by the President, the subject of which was "The Physician, Physically, Mentally, and Morally Considered."

The Society re-assembled at nine o'clock Wednesday morning.

DR. S. WICKES read the report of the Standing Committee:

#### HEALTH OF THE STATE.

The year throughout the State has been marked for the general prevalence of health. There have been no general and few local epidemics.

The reporters of the County Societies report the usual diseases of the seasons. In the southern and central counties, many cases of typhoid fever, apparently due to some infection incurred at the Centennial Exhibition. Burlington County reports a mortality of 116. Local epidemics of scarlatina and diphtheria have prevailed, with more or less virulence, particularly at Heightstown, in Mercer County, where the fatality was 28 per cent. There were 160 cases in 57 families. Cumberland County reports three cases of varioloid in those previously vaccinated, one case having already had the disease. Monmouth County, through its reporter, utters a complaint against the laity for their indifference to vaccination, and recommends a law regarding it. Morris County reports instances of the peculiar history of the epidemics of diphtheria. In some instances it has remained confined to a certain village for a long time, the neighboring villages escaping infection, though in constant communication with the infected place. Suddenly the disease migrates, leaves its previous seat, and breaks out with renewed violence in another town, where it remains as before. This phase in its history offers a very interesting field for inquiry.

## TREATMENT OF WHOOPING-COUGH.

DR. SNOWDEN, of Camden County, notices his success in arresting the paroxysms of whooping cough by alum.

Pneumonia was successfully treated by Dr. Whitaker, of Cumberland County, by Squibb's fluid extract of ergot, 30 drop doses every three hours, fully controlling the disease in five days. Thorough inunction of the skin by warm oil, lard or vaseline, is strongly recommended by Dr. Fisher, of Hudson, in scarlatina. It allays irritation, reduces temperature, tends to prevent sequela, and diminishes the danger of contagion.

## TREATMENT OF ACUTE RHEUMATISM.

For the relief of acute rheumatism, salicine, 8 to 10 grains every three hours, has proved successful. For the same disease salicylic acid is much extolled by Drs. Forman and Griffith.

## TREATMENT OF DIPHTHERIA.

DR. MILLER, of Morris, recommends proto-iodide of mercury in diphtheria, to be given until there is an increased flow of saliva, which attained, the tenacity of the membrane is less, and the patient relieved.

DR. GRIFFITH has much success in the use of guarana in nervous headache. The same observer says that chloride of calcium in many cases will absorb boils, carbuncles, indolent abscesses, felons, and threatened glandular suppurations, with as much certainty as quinia in intermittent.

## CARBUNCULAR INFLAMMATION OF UPPER LIP.

DR. WELCH, of Monmouth, reports a case of carbuncular inflammation of the upper lip in a young lady. Seen on the second day of the disease, the upper lip was enormously swollen, the mucous membrane everted, bearing the deep impression of the teeth. The lip was painful, but there were no constitutional symptoms. The doctor scarified the mucous membrane, which gave partial relief, and adapted a compress wet with ice-water, frequently renewed. The treatment was successful, and he believes that the early treating such conditions in this manner will give more favorable results than other procedures have done.

## POISONING BY TANSY.

The same gentleman reports a case of poisoning by the oil of tansy, taken to produce abortion. The patient, a robust young servant-girl, when seen was in violent clonic spasm, blood-stained mouth, respiration disturbed, pulseless, feeble cardiac action, and with all the signs of impending dissolution. Brandy was administered at first per anum, afterwards by the mouth, and recovery took place. The oil had been taken two weeks in small doses, and at last the patient resorted to a heavier dose. There was no abortion.

## PLACENTA RETAINED OVER EIGHTEEN MONTHS.

DR. MARCY, of Cape May, reports a case of placenta retained for over eighteen months.

## PRECOCIOUS MENSTRUATION.

DR. CRAIG, of Hudson, reports a case of precocious menstruation in a child four years of age, who from that age till ten menstruated regularly. At that age menstruation ceased, to return in four years, and after that she continued menstruating naturally. She enjoyed good health during the entire period. In contrast, he notices a case of prolonged menstruation in a lady now 73 years of age, who is as regular every month as any young woman.

## SANGUINEOUS CYST OF SACRUM.

DR. PIERSON, Jr., of Orange, reported a case of sanguineous cyst of the sacrum: "Dr. L. died Nov. 7, 1876, in the forty-third year of his age. He was never married. Had usually enjoyed good health. His average weight for many years was about 250 lbs. He had never had any constitutional disease.

Four years previous to the time of his death, he received a fall by being accidentally tipped from the end of a table on which he was seated, striking directly upon his buttocks. He experienced considerable pain in the region of his sacrum at the time, and ever afterwards he had more or less pain and tenderness in that region, which he attributed to some injury which the bone had sustained by his fall. He was not so disabled at the time but that he could attend to his professional duties. In about eighteen months he began to have, in addition to the pain, difficulty in defecation. The feces would pass in small lumps or tape-like forms. This difficulty increased until it became most distressing and agonizing; at times he would be several hours in relieving the rectum of a very small quantity of fecal matter, and this would be accomplished only by walking up and down the room, or lying on the floor, resting on his hands and knees. His bowels were not relieved in any other manner for more than a year previous to his death. The tenesmus was so constant and distressing that the only way the doctor could keep about at all was by the use of opium suppositories. Retention of urine was another of his troubles, and for at least six months previous to his death the only way he could relieve his bladder was by using the catheter, or by forcibly forcing the water out by pressing with his hands upon the bladder from above. Frequent examinations of the rectum were made with the finger, bougie, and speculum, and always with negative results. All that was ever observed on examination was a fulness in the posterior wall of the rectum, a few hemorrhoidal tumors, and a small ulcer in the rectum. Had the hand been introduced into the rectum a more accurate diagnosis of the case would probably have been made; but perhaps it is well it was not done, as the hand would probably have ruptured the tumor, and fatal hemorrhage have followed. About two months before his death a tumor was observed in the lower part of the abdomen, though the doctor had insisted some time previously that he could feel one. The tumor gradually increased in size until it nearly extended from one iliac region to the other. It was smooth, round, and did not pulsate, and had much the appearance of a full bladder. Prof. H. B. Sands, of New York, saw the patient after this tumor was discovered, and gave his opinion that it was some form of neoplasm, involving the intestine and bladder. Drs. Wilmarth, Chandler, and Butteus, who were present, concurred in the opinions expressed by Dr. Sands. Dr. L. himself always insisted that there was a tumor growing from his sacrum, which caused the difficult defecation by its pressure on the rectum, and the retention of urine was due to the tumor forcing the bladder from its normal position. The post-mortem proved the correctness of his theory. His sufferings at last were unbearable, and his only relief was in the inhalation of chloroform, of which he used about a pound daily. It is not improbable his death may have been hastened by its use.

*Post-mortem.*—The abdomen being opened, the bladder was seen pushed entirely above the pubes and a tumor blocking up the pelvic cavity, and extending into the general abdominal cavity. It looked like a rectum distended with fecal matter. The peritoneum

extended in a fold across it, apparently bending it down. Further dissection showed that the rectum, which was spread out over the tumor, could be entirely separated from its anterior wall, to which it was connected by dense areolar tissue.

The tumor could be dissected from the anterior wall of the sacrum for the distance of two inches; below that no further separation could be made between them, without rupturing a strong membrane which was reflected from the sacrum over the anterior surface of the tumor. It was also easily separable from the sides of the pelvis. Externally, it presented a dense fibrous appearance on the anterior and superior surfaces; laterally the walls were less dense. An incision was made in the tumor and a reddish serum flowed out; the interior was found filled with dark soft clots. On pushing the finger through them it passed into an opening in the anterior wall of the sacrum; this opening, about the size of a half-dollar, communicated with a cavity in the sacrum, one inch in depth, extending upward farther than the finger could reach, and filled with clots, which were older than those in the tumor. The walls of the tumor were there, a fibrous coat varying in thickness at parts, a thin shell of bone wanting in many places, and a thin serous-like membrane which lined the bone. There were also strings of fibrous tissue stretching across the interior of the tumor. Its only contents were the serum and the clots. The coccyx and other pelvic bones were normal. The liver was fatty, but not enlarged; the ureters dilated, but other abdominal organs normal.

This case seems to be one of those cases which Stanley and others describe as sanguineous bone-cysts. Gross calls them hematoid bone-tumors. All pathologists seem to agree that they are non-malignant, and are frequently the result of local injury. They have been reported as having occurred in the tibia, femur, clavicle, scapula and maxillary bones. This is the only case of which I have any knowledge of the disease occurring in the sacrum.

#### REPORTS OF DELEGATES.

The delegates to corresponding societies made their reports, and the gentlemen present from corresponding societies were cordially and formally welcomed by the President, and each on his presentation duly responded.

#### THE METRIC SYSTEM.

The Committee on Metric System of Weights and Measures, reported by Dr. Oakley, appending which report is the following resolution, which was adopted by the Society:

*Resolved*, That this Society petition the Congress of the United States, that, after some date to be fixed several years in advance, the metric standards in the office of Weights and Measures shall be the sole authorized public standards of weights and measures.

A committee, of which Dr. E. M. Hunt was chairman, was appointed to memorialize the American Medical Association as to a National Pharmacopœia.

#### A NEW VECTIS.

DR. RYERSON exhibited a new vectis which he had recently devised. He believed it had many advantages over any now in use. A full description of the instrument will appear in the medical journals very soon.

#### CARE OF SKIN AND PREVENTION OF DISEASE.

DR. A. W. ROGERS read a very exhaustive and interesting paper on the care of the skin as a means of prevention and cure of disease.

#### HAY FEVER.

DR. E. J. MARSH also read a paper on "Hay Fever, or Pollen Poisoning," in which he reported experiments confirming those of Wyman, to the effect that the pollen of the ambrosia *artemesiaefolia*, or rag-weed, is the exciting cause of hay fever, or autumnal catarrh.

These experiments were twofold—one class demonstrated the results of exposure to the pollen, the other its wide distribution in the atmosphere.

He found that after every exposure to the influence of the pollen he experienced the well-known symptoms of the catarrh. The gentleman is very susceptible to the disease, having to seek non-catarthal regions every year. He also found that the pollen could be collected on glasses wet with glycerine, in town and country, and at various heights from the surface throughout the flowering season.

He compares the disease to that caused by poisoning by the rhus toxicodendron—where we find the same symptoms of severe local inflammation, with little febrile movement, but more or less nervous disturbance. In both cases there is a varying grade of susceptibility, some not being affected at all, while others will have a very severe attack when exposed merely to the minute amount of volatile acid in lung poisoning, and to the minute particles of the germative matter in pollen poisoning.

They differ, in that in the one there is usually but one exposure, in the other the influence is continuous.

He cites as arguments in favor of the pollen theory Blackley's experiments on the irritant properties of the pollen of grasses, its great prevalence in the atmosphere, and its agency in the production of the English hay fever. Dr. Wyman's and his own experiments with ambrosia, the coincidence of the commencement, course and termination of the disease with the blossoming period of the ambrosia.

The existence of catarrhal and non-catarthal regions, and the distribution of the ambrosia which is present in the one, absent in the other, the insufficiency of other assigned causes, and the local character of the disease—this last point doubted by many—he considers the true view. He considers the susceptibility to be due to an idiosyncrasy which, though constitutional, is not the disease or its proximate cause.

He further holds, with Wyman, that the effect varies in proportion when the plant grows in different regions, and that it possesses irritant power in the critical period only.

The therapeutics of the disease the doctor finds very unsatisfactory. Migration to those regions where the ambrosia is not found is the only known means of escape from the continued exposure. During the attack he recommends hypodermics of morphia, cold water and simple cerate for the eyes and nose, Espéc's cigarettes for the cough, and chloroform for the asthma.

#### OFFICERS ELECT.

The following were elected as the officers of the Society for the ensuing year: President, H. R. Baldwin; vice-Presidents, John S. Cook, A. W. Rogers, and A. N. Dougherty; Corresponding Secretary, Wm. Elmer; Recording Secretary, Wm. Pierson, Jr.; Treasurer, W. W. L. Phillips; Standing Committee, S. Wickes, S. Lilly, and J. L. Bodwin.

Delegates to American Medical Association for 1878: S. Lilly, E. M. Hunt, A. Clendennin, Joseph Parrish, T. F. Cullen, E. E. Bateman, L. F. Hulsey, Wm. R. Fisher, C. Skillman, N. Williamson, I. S.

Long, C. Anderson, C. B. Gordon, Geo. Teniberg, T. Ter-  
rill, P. F. Brakely; New Hampshire—David S. Smith;  
Massachusetts—J. Prendergast, I. B. Coleman, J. M.  
Hall, and T. J. Thomson; Rhode Island—O. Warner,  
Jos. S. Green and A. H. Hopper; Maine—I. Ryerson,  
G. Ballemay and F. Witmarth; Connecticut—A.  
D. Carpenter; New York—D. A. Currie, I. W. Hunt,  
L. W. Oakley and Wm. O'Gorman; Pennsylvania—  
H. G. Taylor, Geo. H. Larison, O. P. Garner, and Wm.  
A. Newell.

The next annual meeting of the Society will be held  
at the Monmouth House, Spring Lake.

### CONNECTICUT MEDICAL SOCIETY.

*Eighty-sixth Annual Convention, May 24, 25, 1877.*

DR. A. W. BARROWS, PRESIDENT, IN THE CHAIR.

(Special Report for the MEDICAL RECORD.)

The Eighty-sixth Annual Convention of the Presi-  
dent and Fellows of the Connecticut Medical Society  
was held in the Representatives' Chamber, Hartford,  
Conn., May 24th and 25th.

DR. A. W. BARROWS, the President of the Society,  
welcomed the delegates in a brief address, and in ac-  
cordance with a regulation of the Society, presented  
several subjects which he deemed worthy their consi-  
deration. Among other matters he referred to the

#### FREQUENT MISTAKES IN PRESCRIBING AND DISPENSING MEDICINES,

and suggested that measures should be adopted where-  
by a better understanding might exist between the  
prescriber and dispenser of medicine.

#### THE REVISION OF THE U. S. PHARMACOPEIA

also received attention, and although no positive opin-  
ion was expressed regarding the best course to pursue,  
he was inclined to lean towards the plan proposed by  
Dr. Squibb.

After a brief recess for the delegates from the vari-  
ous county societies to appoint one of their number as  
a member of the Nominating Committee, the Conven-  
tion was again called to order and the usual com-  
mittees appointed by the President.

The unfinished business of the preceding year was  
disposed of by the adoption of the amendment, mak-  
ing the Treasurer a member of the Committee of Pub-  
lication.

#### RELATION OF DRUGGISTS AND PHYSICIANS.

There was a very lively debate on the relation be-  
tween druggists and physicians, and the understand-  
ing which should exist between them.

DR. CHAMBERLAIN remarked that as there was little  
liability of change in the laws relating to the sale of  
powerful remedies and poisons, or allowing the indis-  
criminate repetition of prescriptions calling for narcot-  
ic, emetic, or emmenagogue drugs, whatever could  
be accomplished in the matter must be done by united  
action on our own part, and conference with the phar-  
macists who are willing to assent to any reasonable  
regulations. There should also be some method agreed  
upon of designating that the physician has carefully  
read over the prescription, and assumes all responsi-  
bility when unusually large doses of powerful drugs  
are called for. Often, in emergencies, large doses are  
demanded when the delay to verify the prescription  
would be fatal; inquiries of the purchaser in such  
cases engendered suspicion and loss of confidence.  
The directions plainly marked should, in all cases, ac-  
company the prescription. We might then consider

any mistakes due to negligence of such precautions as  
criminal.

DR. C. M. CARLETON offered the following:

#### PRESCRIBING DRUGGISTS.

*Resolved,* That we, as physicians, will not allow our  
prescriptions to be dispensed by any druggist who  
shall himself prescribe for any disease, or allow any  
clerk or assistant in his employ to prescribe.

In support of the resolution, he stated that the evil  
was one of great magnitude, both to the physician,  
who was thereby defrauded, and to the patient who  
was made to suffer from the unskilful treatment. The  
remedy for this lay within the power of the physicians,  
if they would exercise it.

DR. LINDSLEY thought that little could be accom-  
plished by hasty action or by implied threat, and  
that it would be difficult to secure concerted action.  
He spoke of the pharmaceutical associations as com-  
posed of honorable men, and suggested a conference  
with them.

DR. CARLETON said that counter prescribing had  
been fully suppressed in Lynn, Mass., by concerted  
action of the druggists and physicians, and offered the  
following substitute for his resolution, so that it  
should read: "Any druggist who shall prescribe, or  
allow any one in his employ to prescribe, violates the  
proper and just relations which should exist between  
the physician and druggist."

After considerable debate, the whole matter was  
referred to a Committee on the Relations between  
Physicians and Druggists, who were to act as dele-  
gates to the State Pharmaceutical Convention, and  
report at the next convention. The subject of the  
revision of the Pharmacopœia was also referred to the  
same committee.

The Chair appointed Drs. Wainwright, of Hartford;  
S. H. Bronson, of New Haven; Buke, of Middle-  
town; M. C. White, of New Haven; Chamberlain, of  
Hartford.

On motion of Dr. Chamberlain, a committee was  
also appointed by the Chair to report to this Conven-  
tion concerning the proposed revision of the Pharma-  
copœia. Drs. Lindsley, Woodward, and Catlin were  
appointed.

#### STATE BOARD OF HEALTH.

The Committee on a State Board of Health, consist-  
ing of Drs. E. K. Hunt, C. A. Lindsley, and C. W.  
Chamberlain, reported the defeat of the bill drawn up  
by them, and expressed but small hope that the  
measures proposed would be adopted.

The report was accepted by a unanimous vote. Dr.  
Lindsley deplored the unsatisfactory state of the regis-  
tration of vital statistics in this State, and the ill-  
considered action of the Legislature. He moved that we  
still continue to urge the matter; that it could not be  
possible that any body of intelligent men could long  
remain ignorant of the benefits of such a plan, or need  
much urging to adopt it. After some further debate,  
the motion to appoint a committee was passed, and  
the President appointed Drs. Lindsley, Chamberlain,  
Jackson, Knight, and Lewis Williams.

#### OFFICERS ELECT.

The following officers were elected for the ensuing  
year: President, Dr. R. Hubbard, of Bridgeport; Vice-  
president, Dr. C. M. Carleton, of Norwich; Treasurer,  
Dr. F. D. Edgerton, of Middletown; Secretary, Dr. C.  
W. Chamberlain, of Hartford; Committee on Matters  
of Professional Interest, Dr. W. A. M. Wainwright, of  
Hartford, Dr. H. W. Bacl, of Litchfield, Dr. A. Wood-  
ward, of Franklin.

The Treasurer's report showed a balance to the credit of the Society of \$207.96.

After the transaction of some routine business, the Society adjourned until 9 A.M. of the day following.

#### SECOND DAY.

The Society met, pursuant to previous adjournment, Thursday, at 9 A.M.

#### OBITUARY RECORD.

The Secretary presented the statistical record of the past year. Two honorary members had died—Dr. Walter Channing and Dr. Gurdon Buck, of New York—men upon whom it was impossible to confer honor, but who not only honored members, but the name of physician. Eight of the members had been removed by death—including one former president, Dr. Wm. Cogswell, of Plainfield—and for the most part, of those far advanced in years. Twenty-three new members have been added, making a clear gain of twelve, including in the account those who have left the State.

#### PRESIDENT'S ADDRESS—MALARIAL FEVER IN NEW ENGLAND.

The President, Dr. A. W. Barrows, presented the annual address, on Malarial Fever in New England, commencing with a brief historical sketch from the early chroniclers of New England. Josselyn specified fever and ague as among the diseases then indigenous in 1671. Hubbard spoke of the "seasoning" or "ague fever" in 1678 in New Haven, and warned against blood-letting as deadly. Cotton Mather and Davenport spoke of malarial fevers, especially in Connecticut. The Housatonic Valley and parts of the Connecticut Valley were affected soon after settlement, disappearing during the eighteenth century, except where the land was overflowed from dams, leaving tracts partially covered with water, or exposed at periods. Many instances of this kind were detailed, the type generally tertian. In the valley of the Connecticut, contrary to the statement of Dr. N. Smith, intermittent fever had been endemic in 1824, in Northampton and many other places. In 1831 there was an epidemic in Norwalk, affecting more than half the population, and it has been indigenous in the shore towns from year to year. From 1850 it began to be prevalent in New Haven, soon suggesting the idea of a change of diathesis, rendering quinine a much more serviceable remedy. In 1853 the disease reappeared in Fairfield Co., and still occurs sporadically. It gradually extended northward, reaching Hartford in 1872, though sporadic cases have occurred since 1856 in this county. The first cases in the city occurred in the southern portions, near the embankments of the Valley R.R. There was also a sluggish stream polluted with sewage near.

The disease had prevailed in that region, where the upturning of earth and obstruction to the natural drainage had been marked, and had already reached a point about ten miles north of this city. The appearance of the disease in various localities was traced, and local causes assigned, in many extensive upturnings of the soil, embankments for reservoirs, half-covered islands, partially dried ponds, etc. The following theories of the origin of the disease were discussed: 1st. The paludal from the exhalations of marshes. 2d. Aërial transmission of some specific contagium or spores cells or bacteria. 3d. Change of diathesis. 4th. Change of climate. Neither of these are conclusive or satisfactory; the claims of each and the objections were discussed at length without a denial of

either. There are questions concerning the entire subject yet unsolved which none of the theories solve.

#### MEDICAL REPORTS FROM THE COUNTIES.

DR. LINDSLEY then presented the report of the Committee on Matters of Professional Interest in the State. The year has been one of unusual health. Mild epidemics of scarlet fever, measles, whooping-cough, had prevailed. The type of all diseases seems to be modified by malarial influence, and typhoid and intermittent prevail in inverse ratio. Some cases of typho-malarial occur. School hygiene was briefly discussed, the reports being very incomplete on this point. The plan devised by Dr. Lindsley of securing reports from different portions of the State has been very successful, and it was with extreme regret that the Society learned that his duties would no longer permit him to retain the position he has filled so profitably to the best interests of the Society.

The delegates from other Societies—Dr. N. A. Wersom, of Portland, from the Maine Medical Society, Dr. John W. Blodgett, from the New Hampshire Society—were welcomed by the President and presented to the Society. A letter was also received from Dr. Bradford, of Homer, New York, regretting his inability to be present.

#### REVISION OF THE PHARMACOPEIA.

The Committee on Revision of the Pharmacopœia, appointed the previous day, reported that no action was advisable at present, though deprecating any that would lead to the publishing of two volumes. The report, after considerable debate, was adopted.

#### PATHOLOGY OF THE PNEUMOGASTRIC.

DR. J. CAMPBELL, the essayist, presented an elaborate paper on the Pathology of the Pneumogastric Nerve. The relations with the sympathetic and its obscure reflex relations were very ably presented.

Voluntary communications occupied the remainder of the session.

DR. DEMING, of Litchfield, discussed some of the relations of temperament and age in producing phthisis.

#### LACERATION OF THE PERINEUM.

DR. STORRS, of Hartford, presented a modification of the usual method of operating for lacerated perineum, by which vaginal and rectal lines of support were formed, and the natural contour of the perineal wedge secured without crowding the deeper portions of the laceration, requiring no deep stitches along the perineal line. He also gave the details of several successful cases of operations in vesico- and recto-vaginal fistula where other operative procedures had failed.

#### PUERPERAL MANIA.

DR. C. B. MAY presented a very valuable statistical paper on the treatment of the cases of puerperal mania which had been received in the institution at Middletown, and the comparative results obtained.

#### SPASMODIC STRICTURE OF THE OESOPHAGUS.

DR. CHAMBERLAIN then read a paper on spasmodic stricture of the oesophagus, presenting an abstract of the literature of this somewhat rare affection, and giving the details of the successful treatment of two cases.

In the absence of Dr. Halleck, of Middletown, in Europe, the Secretary read a very instructive and exhaustive paper by him, discussing the cottage plan of treating insanity.

## THE POINT OF ELECTION IN AMPUTATION.

DR. WAINWRIGHT, of Hartford, presented two interesting surgical cases under his charge. The one was that of a girl, with both legs crushed by a locomotive, afterwards amputated, and who now walked about on artificial limbs. She was under the worst sanitary influences, yet recovered quickly. The other was a peculiar case of gunshot wound of the arm, with extensive bleeding, and inability to find the ball. A very interesting part of Dr. Wainwright's paper consisted of a letter from Mr. Douglas, the manufacturer of artificial limbs, in Springfield. The Doctor had written to Mr. Douglas, to get his opinion of the proper point of operating, in order to have the best available stump for artificial limbs. The letter was rather long, and the gist of it was this: Eight inches below the knee, ten inches below the body, and, in stiff knees bent, one inch from the joint, are the preferable points.

The hour for dinner having arrived, the Society adjourned to Merritt's Café, where a few hours were very pleasantly spent in discussing the bill of fare, and in that social recreation that physicians enjoy the more heartily from the rarity of the occasions that they are permitted to leave the active duties of a laborious profession.

## Correspondence.

## THE COURSE OF THE MEDICAL DEPARTMENT, UNIVERSITY OF PENNSYLVANIA.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—In your recent very full notice of the changes which are about to go into operation at the University Pennsylvania in medical teaching, occur two or three errors which we would be glad to be permitted to correct.

*First, as to preliminary examinations:* For various reasons it has not been deemed advisable to institute these immediately. But it is evident that the graded course, with examinations at the end of each year, to be successfully passed before the student can advance to the next year, will have a similar effect in eliminating those not qualified to study medicine.

*Second, as to the studies of each year:* The *first* will be devoted to anatomy by lectures and dissections; materia medica and pharmacy, by lectures and laboratory work; general chemistry by lectures and laboratory; physiology by lectures; and obstetrics by lectures, with examinations on general chemistry, materia medica, and pharmacy, at end of first term. The *second* year will include anatomy by lectures, normal histology by laboratory work, surgical anatomy by lectures, therapeutics by lectures, medical chemistry by lectures and laboratory work, physiology by lectures and laboratory, morbid anatomy by lectures, obstetrics by lectures, theory and practice of medicine and surgery by lectures and general medical and surgical clinics, with examinations at end of second year in anatomy, physiology, and medical chemistry.

The *third* year will be devoted to therapeutics by lectures, morbid anatomy by lectures and laboratory work, didactic gynecology, theory and practice by lectures, surgery by lectures, operative surgery by operations, general medical and surgical clinics, bedside instruction in medicine and surgery, practical instruction in ophthalmoscopy and electro-therapeutics, with special clinics on nervous diseases, diseases of the eye and ear, and diseases of women and children. The

examinations at the end of the course are in therapeutics, morbid anatomy, theory and practice of medicine and surgery.

*Finally, as to fees:* They are, for matriculation, \$5; for the first year, \$140; for the second year, \$140; for the third year, \$100; dissecting fee, \$10, but no charge for material.

Respectfully yours,

JAMES TYSON, M.D.,  
Secretary of the Faculty.

PHILADELPHIA, May 25, 1877.

## PROFESSIONAL DUTY AND SACRIFICE OF LIFE.

DEAR SIR: I notice in the 342d number of the MEDICAL RECORD an article entitled "Professional Duty and Sacrifice of Life," in which you express the hope that some efficient instrument may be constructed, which shall relieve the surgeon from the dangers accruing from sucking the windpipes of patients suffering from croup, after the performance of tracheotomy.

In the absence of such instrument, I would respectfully submit the following simple plan, which proved very successful in two cases of croup which fell under my notice in the Roosevelt Hospital. I took a Davisson Syringe and removed the leaden weight from the end, which rests in the basin, then applying this end to the opening, I exerted suction in the usual way and continued to exert suction till the syringe clogged; upon gently withdrawing it from the wound a long string of false membrane was brought away. Every time the syringe was used it worked well, and completely cleaned the trachea. As a syringe can always be obtained, this I think will be found a very useful means of saving the patient's life and preventing more than necessary risk to the surgeon.

FRANK B. GREEN, M.D.

443 GATES AVENUE, BROOKLYN.

## Medical Items and News.

LIGATION OF THE EXTERNAL ILIAC.—Dr. W. T. White ligated the external iliac artery, May 24, 1877, at the Presbyterian Hospital, for aneurism of the femoral, high up. This is the third operation of its kind which has been performed during three successive weeks in the different hospitals of this city. The first by Dr. C. M. Allin at the New York Hospital, the second by Prof. James R. Wood at Bellevue, and the third by Dr. White, as stated.

LIBRARY OF THE NEW YORK HOSPITAL.—Dr. J. L. Vandervoort, the librarian of the New York Hospital, writes: "In 1876, four hundred and sixteen volumes were added to our former number, and ninety pamphlets.

"In the present year, to date, May 26th, three hundred and thirty-one volumes have been added. Our total number of volumes, exclusive of duplicates, amounts to 10,567.

"Dr. Purple, in his address, says, the average yearly increase has been about 125—dating from the foundation of the Library, but he said nothing about its yearly increase in later times. I spoke to him about this statement, and told him that it was calculated to do injustice. Had he expressed himself somewhat differently as he easily could have done, his statement would have appeared quite otherwise.

"I simply write this note to you to correct the statement which appeared in THE RECORD of to-day (April 26, 1877)."

## Original Lectures.

## LECTURES ON FEVERS.

By ALFRED L. LOOMIS, M.D.,

PROFESSOR OF PATHOLOGY AND PRACTICAL MEDICINE IN THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF THE CITY OF NEW YORK.

(Phonographically reported for THE MEDICAL RECORD.)

## LECTURE VIII.

TYPHOID FEVER (CONTINUED)—TREATMENT—TYPHO-MALARIAL FEVER—MORBID ANATOMY.

GENTLEMEN:—When I concluded my last lecture, this question was before us: Is the administration of cathartics ever admissible in typhoid fever? Quite diverse views are still held in regard to what the answer to this question should be. Recently, certain observers of extended experience have claimed that there is sufficient reason for the belief that a portion of the typhoid poison lodged in the alimentary tract may be expelled by the timely administration of cathartics, and thus the severity of the fever be mitigated and its duration shortened. Recent German writers claim that *calomel*, concerning the favorable action of which in this fever so much has been said and written, acts beneficially only as a cathartic. Those who favor the administration of cathartics, recommend their use mainly during the first week of the disease.

On the other hand, equally competent observers maintain that the intestinal changes are augmented, and rendered more extensive by the action of cathartics, that the normal course of the fever is interfered with, and that in a large proportion of cases where intestinal and peritoneal complications occur, hypercatharsis has been induced at an early period of the fever by the administration of cathartics for the purpose of shortening its duration. My own experience leads me to exercise the greatest caution in the administration of cathartics in any stage of this fever. I am confident that the routine practice of administering purgative medicines in the early stage of typhoid fever can only be followed by a threefold injury:

*First.* The patient is weakened.

*Second.* The local intestinal lesions are increased.

*Third.* Perforating peritonitis is more liable to occur.

The administration of cathartics as an eliminative procedure has neither reason nor experience to sustain it.

Before speaking of the management of the convalescence of typhoid fever, I will make a few general remarks on the use of anodynes for the relief of certain troublesome nervous phenomena.

I have to say to you that among the earliest, most frequent, and often most prominent nervous symptoms in this fever is headache, but it is seldom very violent or of long continuance.

Should it be severe, not readily relieved by fomenting the forehead and temples with warm water, or should it give place to active delirium, and other severe nervous disturbances, the question presents itself, shall anodynes be administered? Unquestionably, the most reliable of this class of remedies is opium.

Usually, the condition of the pupil of the eye will serve to indicate to us whether opium shall or shall not be administered. A contracted or "pin-hole" pupil may be considered to contraindicate its use,

though there are exceptional cases in which opium acts favorably, notwithstanding this condition of the pupil.

Opium should be given with great caution whenever signs of cyanosis are present. In all cases of typhoid fever, it is safer to administer opium in small and repeated doses than to venture upon the administration of one large dose.

There are other anodynes which sometimes you will find of service, such as hyoscyamus, the bromides, and chloral. I would caution you against administering too large doses of chloral; the desired effect can generally be produced by ten or fifteen grains. If the first dose fails to relieve, a second may be administered at the expiration of two hours. This remedy is said to have a special value in quieting the active delirium, which is sometimes so troublesome, but my own experience in its use has not been favorable. When anodynes have failed to give relief to typhoid fever patients, who have been delirious and somnolent for days, sometimes they will become quiet and fall asleep immediately after the free administration of stimulants. Those cases in which the nervous symptoms are due to an anæmic condition of the brain, associated with a weak heart and a flagging circulation, are most likely to be benefited by the use of stimulants. In those cases in which subsultus becomes very marked and there is a general tremor, jactitation, and restlessness, I have seen most happy effects produced by the use of hypodermic injections of sulphuric ether. I would use, as an average quantity, two drachms given in injections of one drachm each, in different places.

The same watchful care should be taken of a typhoid fever patient during convalescence as during the active period of the fever.

The number of typhoid patients who die during convalescence is proportionally large. Frequently this is due to the fact that the physician has laid down no strict rules to be observed as to diet and exercise, and frequently from the non-observance of such rules.

The diet of fever patients during this period should be carefully watched. Allow your patient to eat frequently, but only small quantities of food should be taken at a time, so that the gastric juice secreted by the enfeebled stomach may be sufficient for its complete digestion. All indigestible articles of food, and those which furnish a large amount of waste, should be strictly forbidden. An apparently insignificant disturbance of the stomach, a slight vomiting, or a moderate diarrhoea occurring during the period of convalescence should be regarded as dangerous, for any one of these may induce a subacute gastritis, or lead to intestinal perforation and a fatal peritonitis. It is obvious that while the intestinal ulcers are healing, much mischief may be done by improper diet.

Notwithstanding the cravings of the patient's appetite, the diet must be restricted to such articles as milk, cream, gruels, jellies, and animal broths. Solid food must be strictly forbidden, especially meats, vegetables, and fruits. If diarrhoea is present during convalescence it is far safer to restrict the patient to milk and cream. All exercise, except simply walking around the sick-room, should be prohibited. I have had patients convalescing from typhoid fever sink rapidly after a long ride, or after indulging in some violent and fatiguing physical exercise. It is of the greatest importance that this class of patients should keep in the recumbent or semi-recumbent posture until the cicatrization of the intestinal ulcers is completed, which in some instances does not take place for two or three weeks after convalescence is well estab-

lished. If convalescence is slow, small doses of quinine, iron, and cod-liver oil are of service. They should be given after the patient has taken food.

When, during the period of convalescence, diarrhœa is persistent, the patient should be kept in bed, and some of the vegetable astringents, such as catechu, hæmatoxylon, may be employed.

In many cases it is important that you should take the evening temperature for at least two weeks after the commencement of convalescence, for by its range you will be able the more accurately to determine the exact condition of your patient.

When convalescence is delayed, so that at the end of four or five weeks the patient has not regained strength, change of air is indicated.

#### TYPHO-MALARIAL FEVER.

Typho-malarial fever, as its name indicates, has many elements in common with typhoid, and many which ally it to remittent fever. To the term "typho-malarial," however, a different signification has been given by different observers. By one class of observers the term has been employed to indicate the presence of malaria, and also the specific poison which produces typhoid fever.

By another class of observers the term has been employed to indicate the presence of malaria and also a *septic* poison, which differs from the specific poison that gives rise to typhoid fever.

There is still another class of observers who doubt the existence of such a form of fever, and regard the so-called typhoid element as nothing more than a "typhoid condition," liable to be developed in connection with remittent fever, and many other diseases.

The term typho-malarial is a convenient one for the first class of observers, and is one which can be employed by them without confusing the student; whereas, for the second class of observers, it is exceedingly inconvenient, giving rise to confusion, because it does not embrace the views held by them regarding the etiology of the disease.

But we have the term, and I shall employ it as one denoting a fever which is produced by the combined action of a *septic* and a *malarial* poison. As far as possible I shall use the word *septic*, when speaking of the poisons which are associated in the production of the disease; and the term typhoid will be reserved for that peculiar condition known as the "typhoid condition," and for the specific disease known as typhoid fever. You will meet with some cases of typho-malarial fever in which the septic element predominates, and others in which the malarial element is predominant. The preponderance of the leading features of the one or the other of these two forms of fever will enable you to determine with a good degree of certainty the course, prognosis, and treatment of each individual case. The distinguishing lines, however, between these two elements are not always sharply defined, but almost imperceptibly the symptoms dependent upon one poison become mingled with those developed by the other. Both of these elements may be modified in their manner of development and in their morbid anatomy, by the occurrence of various intercurrent complications, such as scurvy, pneumonia, etc.

*Morbid Anatomy.*—The changes which take place in the constituents of the blood in typho-malarial fever, so far as we are yet able to determine, are similar to those which occur in typhoid fever, combined with those which are characteristic of malarial fever; the presence of free pigment granules in the blood is often a strong point in its differential diagnosis.

In connection with these blood changes, there are more or less parenchymatous changes in the internal organs similar to those met with in other forms of fever, and in acute infectious diseases. The *liver* is increased in size, and its cut surface presents an appearance which closely resembles that known as nutmeg liver. Sometimes it presents the peculiar bronzed color of the liver in remittent fever; at other times it very closely resembles the liver of yellow fever. A microscopical examination shows free fat and more or less brown pigment granules in the hepatic cells. In most cases of this fever the *spleen* is enlarged, softened, and of an almost black color. The Malpighian bodies are prominent, and present the appearance on its torn surface of little tumors, which vary in size from a pin's head to that of a pea. The organ is rarely as much enlarged or softened as in typhoid fever. It is always the seat of more or less pigmentation.

No uniform change will be noticed in the *kidneys*, except that of hyperæmia, which will be most marked in their cortical substance.

The *lungs* at their most depending portion are the seat of more or less extensive hypostatic congestion. Splenization of the lungs is not as frequently present as in typhoid fever.

The *heart* is pale and flabby. Its muscular fibres are the seat of a granular degeneration similar to that which takes place in the heart in typhoid fever. Exsanguinated clots more or less firm may be found in its cavities, but they have nothing peculiar about them. They closely resemble those found in persons who have died from failure of heart power. They are rarely, if ever, the direct cause of death. The result of my own examinations of the intestinal lesions of this fever has led me to adopt, for the most part, the descriptions of this fever by Dr. J. J. Woodward, of the U. S. A. In fact, Dr. Woodward's investigations in this direction, may be regarded as exhaustive. That the intestinal changes of typho-malarial fever very closely resemble those of typhoid fever there can be no question; by some they have been regarded as identical, but I think, if we very carefully observe them, some very marked differences can be recognized.

As in typhoid fever, the principal and almost constant changes are to be found in and around the closed follicles of the intestinal tract. These changes are made manifest by the gradual enlargement of the follicles, which, as they enlarge, become more or less pigmented.

At the post-mortem examination of one who has died of this fever, usually, you will find these glands in all stages of this pathological process, from slight enlargement and softening to ulceration of the entire follicle. The summit of the enlarged follicle is the first seat of the ulcer. These ulcers may involve a single follicle, or they may invade the adjacent mucous membrane, and produce ulcers from one-half an inch to an inch in diameter. The largest and most extensive ulcerations are to be found in the ileum, and involving the Peyerian patches. The edges of these ulcers are irregular and everted; their base usually is of a grayish color, often mottled with black points. These ulcers may extend into the submucous tissue, and involve the muscular coat of the intestine, and even perforate the peritoneal covering of the intestines.

In the earlier stages, there is little to distinguish these intestinal changes from similar ones which develop in typhoid fever, except, perhaps, the tendency to the deposit of black pigment in the enlarged follicles. In a later stage, certain peculiarities are pres-

ent, which are often sufficiently distinctive to designate the case as one of typho-malarial fever. For instance, in typho-malarial fever there is a gradual elevation of the mucous membrane surrounding the enlarged follicles, which, if ulcers exist on their edges, reaches a thickness of from three to six lines.

These ulcers differ from those of typhoid fever, in that the enlarged patch rises abruptly from the mucous membrane, and in such a manner, that the summit is often larger than the constricting base. Besides, the umbilical depression so often seen in ordinary typhoid patches prior to ulceration is rarely observed in typho-malarial fever. As I have already stated, the ulcers in typho-malarial fever present ragged, irregular edges, which are usually extensively undermined, in consequence of the erosions extending into the submucous tissue, rather than into the glandular layer of the mucous membrane. This undermining of the edges is much more extensive than in typhoid ulcers.

The mucous membrane between the follicles presents the ordinary appearance of catarrhal inflammation, namely, there is more or less congestion, tumefaction, and in the later stages thickening and softening of its tissue.

The minute anatomical changes which attend the development of these intestinal lesions, as determined by the microscope, do not essentially differ from those which I have already described as occurring in typhoid fever, except that they have no regular stage of development marked by days and weeks, the processes are slower in their development, and the presence of pigment in the enlarged and ulcerating follicles stamp it as depending upon an essentially different exciting cause. Hence, although the intestinal lesions of this fever very closely resemble those of typhoid, they are not identical, but evidently belong to another type of disease. Undoubtedly, there are cases in each of these two forms of fever, between which, by the intestinal lesions alone, it is impossible to draw the line of distinction but in typical cases this is easily done.

Intestinal perforation, and a consequent peritonitis, the result of the intestinal ulceration, may occur in typho-malarial fever, but such an accident rarely occurs. Usually, the mesenteric glands are more or less enlarged, and in the advanced stages of the disease, more or less softened. They are of a livid color, and more or less pigmented. The greatest enlargement of these glands will be found in that portion of the mesentery which corresponds to the most extensive and advanced intestinal changes.

The principal changes in the structure of the glands are similar to those which occur in a purely inflammatory process.

Occasionally, minute ulcers are met with in the mucous membrane of the stomach and large intestines.

*Etiology.*—It is difficult to determine the true etiology of typho-malarial fever. That malarial poison is necessary for its development there can be no question. It is equally certain that some other poison besides malaria is in operation whenever this fever prevails. That this poison is not the specific poison of typhoid fever is apparent from the fact that its development and spread, as far as can be determined, is in no way connected with the excrements of one suffering from this fever.

There are two or three facts connected with its development which are now well established:

*First.* It is only met with in malarial districts.

*Second.* In the majority of instances, when this fever has prevailed, its development has been preceded or

attended by marked and readily recognized anti-hygienic conditions, such as overcrowding, bad sewerage, and other conditions favorable to the development of septic poison.

*Third.* That it is a non-contagious disease, and is never propagated from the affected to the healthy, either directly by personal contagion, or indirectly by morbid excretions.

It cannot be regarded as a new disease, but in its morbid anatomy and symptomatology is a combination of two well-recognized forms of fever. The special symptoms and lesions of one or the other of these fevers stamp its character, and indicate its alliance to a malarial or septic type of fever.

*Symptoms.*—It is even more difficult to present a typical picture of this than of typhoid fever. To give you even an outline of its symptoms which shall be approximately true of all, or even the majority of cases, is impossible. Its clinical history varies as the malarial or septic element predominates. Besides, there are a large number of cases in which neither of these elements can be said to predominate, for the patient almost insensibly passes from a malarial into a typhoid condition. There are also certain anti-hygienic conditions which may be present which give to the fever an unusual and peculiar type. For example, when those conditions exist which favor the development of scurvy, if typho-malarial fever is prevailing, as the patient enters upon the second week of the fever, the scorbutic phenomena will become prominent.

At times the dysenteric element may be engrafted on this fever, which shall greatly modify its course, and lead to a train of symptoms, and morbid changes which shall very closely ally it to epidemic dysentery.

The course of this fever may also be greatly modified by certain local complications which are especially liable to occur during the second or third week. The presence of any of these conditions will greatly change its clinical history, but the phenomena which attend its early development will always be sufficient to determine its true character.

In considering in detail the symptoms of this fever I will first describe that class of cases in which the malarial element is predominant.

This type of fever is usually ushered in by a distinct chill. In some instances no premonitory symptoms are present, in other cases the chill is preceded by wandering pains in the limbs and back, headache, loss of appetite, and a feeling of great exhaustion. In a large proportion of cases, in the early stage, the countenance has a peculiar waxy, clay-colored, or yellowish tinge. The chill varies in duration from half an hour to an hour, and in character closely resembles the chill of simple remittent fever. It is immediately followed by active febrile symptoms, the temperature rising in a few hours to 103° F. or 104° F. The pulse reaches 100, and is full and forcible. The excretions are all checked, and there is mental disturbance and sometimes delirium. When once established the fever pursues a variable course. At its onset, and for the first few days, its phenomena often closely resemble those of simple remittent fever, though the remissions are never so well defined as in remittent, and there is at the very onset of the fever an amount of intestinal disturbance which is rarely present in simple remittent. The existence of abdominal tenderness, especially in the right iliac fossa, is a strong point in the differential diagnosis of typho-malarial and simple remittent fever in favor of the former. As the temperature rises, nausea, vomiting, and epigastric tenderness are present in a greater or

less degree. These gastric symptoms bear a close resemblance to those which attend the development of remittent fever, while the intestinal and abdominal symptoms are similar to those of typhoid fever. Diarrhoea may precede the chill; in most cases it is present during the period of fever. At first, the tongue presents a pale, flabby appearance, with a smooth surface, soon it becomes covered with a white or yellowish-white coating, later it becomes red and the coating becomes brownish; in severe cases it may suddenly become clean, red, and shining, and sordes may collect upon the teeth and lips.

Throughout the whole course of the disease there is a marked tendency to periodicity, the exacerbations usually assuming a tertian type. In fatal cases, as the patient reaches the second or third week, the symptoms are very like those of fatal typhoid fever; the prostration becomes more and more complete, the pulse reaches 130 or 140, is feeble and irregular, the patient gradually passes into a state of stupor and coma, involuntary evacuations take place, and death ensues.

In cases that recover, symptoms of amendment may be noticed between the tenth and twentieth days. The tongue begins to become clean, the abdominal symptoms subside, the pulse becomes less frequent and fuller, the disturbance of the nervous system disappears, the appetite gradually returns, and the patient enters upon a tedious convalescence, which is attended by more or less diarrhoea, mental stupor, cardiac irritability, and a slow return of mental and physical vigor.

## Original Communications.

### A CASE OF OVARIOTOMY BY THE ANTI-SEPTIC METHOD.

By W. F. ANDERSON, M.D.,

SALT LAKE CITY, UTAH.

In July, 1876, was called to visit Mrs. C., a married lady, *et. 42*, the mother of one child about twelve months old. She gave the following history. Was fourteen when her menses appeared, had two abortions about three years since, previous to her first pregnancy. Twelve months since, immediately after her delivery, she first observed a hard swelling low down in the left side, which gradually increased in size. Has menstruated regularly (usual amount, with some pain) for some months past. On examination, found the whole abdomen occupied by a large, knobby tumor, fluctuating in some portions, solid in others, no particular pain on pressure, though during its growth had suffered severe pain in several portions of the abdomen; moves her body with ease and freedom, appetite and digestion good, no emaciation, sleeps well, no leucorrhoea.

*Diagnosis.*—Ovarian cyst. The weather being extremely warm, advised her to go home (a hundred miles south), and return in cool weather to be operated on. In January, 1877, was much increased in size, tumor growing rapidly and general health slightly failing; womb normal, moving freely with the sound. My associate, Dr. J. S. Richards, aspirated a prominent cyst, drew a pint or more of serum, which he tested and found loaded with albumen. January 31, 1877, after administering chloroform and maintaining its influence with ether, assisted by Dr. Smart, U.S.A., Drs. Benedict, Hamilton, Fowler, and Richards, a six-

inch incision from umbilicus to pubis was made under a continuous carbolic spray from Sass's Atomizer, which was kept in constant play during the operation. Several cysts were tapped, a quantity of the serum unavoidably flowing into the peritoneum, some extensive adhesions to the abdominal walls first tied with animal carbolized ligatures, then severed. The cyst was removed with some difficulty, its rather broad pedicle tied securely with the same ligatures, severed with the *écrasoir*, and returned. The womb and remaining ovary found healthy. The pelvis carefully cleansed of serum and blood, the incision closed with deep-seated and superficial ligatures, an eight-inch rubber tube extending into the depths of Douglass's pouch left in the lower part of the incision. Prof. Lister's carbolized dressings applied, and the patient, frightfully prostrated (the operation having consumed over an hour), removed to a comfortable bed. Opium and cayenne freely given; brandy, milk, and beef tea *ad lib.* Room well ventilated through a fireplace, and the atmosphere kept constantly impregnated with carbolic acid vapor, and a steady temperature of about 80° F. maintained. Reaction came on in about twelve hours, and not an untoward symptom manifested itself during recovery. Record made twice daily, temperature averaging about 100° F., and pulse between 80 and 90. Dressings removed and fresh reapplied on the eighth, and the bowels moved by injection on the tenth day. In three weeks the patient walked about the room and ate breakfast at the table. Early in March returned home in good health. The solid portion of the cyst weighed seven pounds, being multilocular and containing nearly two gallons of serum.

### A CASE OF FOREIGN BODY IN BRONCHIAL TUBE.—SPONTANEOUS EXPULSION FIVE MONTHS AFTER.

By JAMES A. BREAKELL, M.D.,

NEW YORK CITY.

M. C., *at. four years*, while playing with a piece of the shell of a peach-pit, put it in her mouth, and during the respiratory act, drew it into her trachea, October 14, 1876. She was seized with a violent paroxysm of coughing, but failed to expel the foreign body. A few days after this occurrence I saw her; she was then suffering from an attack of pneumonia, confined to the upper portion of the right lung.

The patient passed from my observation to the care of Dr. J. L. Little, who requested Dr. J. R. Leaming to see the case with him, and a diagnosis of a foreign body in the third branch of the first division of the right bronchus, the same place as that of the button case in Dr. Markoe's practice, was made.

All efforts to induce the friends to have tracheotomy performed for the removal of the foreign body proved unavailing, and the child was left, as supposed, to her fate. She, however, gradually recovered from the affection of the lung, and remained well for about one month, when I was called to attend her. She was again suffering from pneumonia in the same situation, which passed through the usual stages, and ended in recovery. The patient suffered considerably from cough and fetid breath for about three weeks after the accident until April 13, 1877, when she was seized with a convulsion, followed by a violent paroxysm of coughing, during which the foreign body was expelled after having been in the lung for the period of five months. The child has since done well.

The piece was triangular in shape, weighing three grains, and the perimeter being one and three-eighths inches.

## A CASE OF POISONING BY CONTACT OF THE POWDER OF RESIN OF PODOPHYLLUM.

By DAVID WEBSTER, M.D.

ASSISTANT SURGEON TO MANHATTAN EYE AND EAR HOSPITAL, NEW YORK; CLINICAL ASSISTANT IN OPHTHALMOLOGY TO THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

THOMAS C., æt. 17, native of New York, chemist's assistant in a wholesale druggist's establishment in this city, consulted me at Dr. Agnew's clinic at the Manhattan Eye and Ear Hospital, on Wednesday, Jan. 10, 1877, in regard to inflammation of his eyes.

Mr. C. said that on Monday, the 8th inst., he was engaged for five hours in powdering the resin of podophyllum. The podophyllum was placed in a two-gallon mortar and powdered by means of a heavy pestle—he necessarily bending over the mortar while thus engaged. The volatile powder flew up into his face and eyes, but not more than is usual in the levigation of dry, light, volatile substances.

The next morning, Tuesday, while washing his face, he first noticed that his eyes were red and the skin about them discolored. The discoloration extended over the whole of his face, his forehead, and the front part of his neck during the day, and the following night his eyes became so painful as to prevent sleep.

When he presented himself at the hospital on Wednesday, all the parts which had been exposed to contact with the powder were of a yellowish-red color, but not swollen to an appreciable extent. The ocular conjunctivæ were much injected, the palpebral only slightly, the pupils small, the eyes painful and sensitive to light. I instilled a two-grain solution of sulphate of atropia four times at intervals of fifteen minutes before I succeeded in dilating the pupils. There were no signs of iritis, but there seemed to be a reflex spasm of the sphincter iridis which caused it to resist the action of atropine.

I gave the patient a two-grain solution of atropine to drop into each eye three times a day, and a borax wash for the whole affected surface, to be applied also three times a day.

I saw him last on Saturday, the 13th, when his eyes had resumed their normal appearance, except that the pupils were dilated, and the skin of the face and neck had lost its unnatural color. A few small pustules were scattered over the chin and throat.

I stopped the atropine and directed him to continue the borax wash until the pustular eruption should have disappeared.

Mr. C. informed me that he knew of three other druggist's assistants who had been similarly affected from the contact of powdered resin of podophyllum.

**PHOSPHORESCENT SWEATING.**—While the subject of phosphorescence in marine animals was under discussion at a society meeting in Florence, Professor Panzeri cited the case of a medical man, who, after eating fish, felt indisposed, had nausea, and sweats that were luminous. This idiosyncrasy was laid to the *pesci bandiera*, a Neapolitan fish. Dr. Borgiotti, another member of the Academy, also narrated a case of phosphorescent sweating in a patient with miliaria, a fact which has previously been noticed.

## Progress of Medical Science.

**SUTURE OF TENDONS.**—M. Notta, of Lisieux, has published two cases in which tendons were united by metallic sutures, and where union took place by first intention, and without adhesion to the skin. In two other cases the wound suppurated, and accordingly union was by second intention, and yet there was no subsequent adhesion. This result is thought to be due to the fact that the tendon alone was involved, and that the limb was kept absolutely immovable. M. Terrier, remarking upon the cases, thought that in either case, whether union took place by first or second intention, there was adhesion between the skin and the tendons, but that exercise had stretched them apart. With the use of catgut and Lister's dressing, he thinks suppuration may be dispensed with.—*Journ. de Méd.*, May, 1877.

**LEUKEMIC TUMOR OF THE NECK TREATED BY IODIDE OF POTASSIUM.**—The following case is of interest as shedding light upon the treatment of a very rebellious affection: A child, three years of age, came under the care of Dr. Cabot with a tumor of the neck of eighteen months' standing. It had grown rapidly during the preceding few months, and was lobulated and hard, though freely movable, and extended from the ear to the clavicle, and from the median line in front to the transverse processes of the vertebrae. There was no enlargement of the spleen or lymphatic glands. The microscope showed that the proportion of white blood-corpuscles was twice the normal amount. The boy was at first ordered five drops of the iodide of iron three times a day, but, as diarrhœa ensued, it was soon suspended. Two grains of iodide of potassium were then given twice a day in milk, with an ounce of brandy daily as a stimulant. From this time his general health commenced to improve and the tumor softened. Six grains of the iodide were then given daily; iodide of lead ointment was used locally, and a poultice at night. After two months and a half the tumor had diminished two inches in size, and the white corpuscles were normal in amount. Unfortunately, while the treatment was being successfully continued, the child died of diphtheria.—*Boston Medical and Surgical Journal*, May 10th, 1877.

**THE SULPHATE OF CINCHONIDIA AND THE SULPHATE OF QUINIA.**—Professor Love, of Atlanta, noting the difference in effect between the two remedies, says that there are some in favor of cinchonidia. This latter has less action upon the nervous system; there is with it less cerebral fulness, less ringing in the ears, and less deafness and disturbance of vision or vertigo. As a cardiac sedative their action is about the same. Where quinine produces muscular prostration, coldness of the surface, and, in heroic doses, prostration and collapse, cinchonidia has not been noticed to have any different effect. As the result of extensive practice within a malarious district, where acute cases were apt to become chronic, quinine was not found so efficient as the preparations of bark containing other or all the alkaloids. In such cases he believes that cinchonidia will be found more effective than quinia. Indeed, he has been in the habit of prescribing cinchonidia in the same doses, forms, and formulae as quinia, except in some few acute cases where the active *explosive* power of the latter seemed to be indicated to meet a paroxysm; where, however, there were indications for a *siege* treatment rather than by *storm*, he thinks that an advantage other than pecuniary will be found in the sulphate of cinchonidia.—*Atlanta Medical and Surgical Journal*, May, 1877.

# THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, June 9, 1877.

## THE MEDICAL TREATMENT OF UTERINE DISEASE.

THE second meeting of the American Gynecological Association was held in Boston last week. The attendance was good; the papers read and the discussions held were of a character to do honor to the Society and to the members taking part. The address of the retiring President, Prof. Fordyce Barker, was upon a subject which, although not a very fashionable one at present, is certainly deserving of some little attention. Without wishing to ignore the just claims of operative gynecology, he very properly urged the giving of more attention to the medical treatment of uterine disease. There is no doubt that this latter branch of our science has been too much neglected—that many operations have been done more because they were fashionable than for any good conferred by them upon the patient. It is so easy to gain credit by such procedures, that it is no wonder that so many yield to the temptation. Then, again, the uterus is so non-retaliatory, that it invites all sorts of inroads upon its textural integrity. The shedding of uterine blood apparently begets an insatiable for gynecological operations, which, when once established, is sometimes dreadful to contemplate. Cases are on record in which surgeons have timidly begun with incising the os, then with excising the cervix, body, and fundus of the uterus; and lastly, when ovaries were included in the ablation, have actually mourned that nothing more was left to conquer. The fact that some of these patients get well may help to prove that, gynecologically speaking, the uterus and appendages are incumbrances. But the other side of the argument is, that women who are not operated upon, whose uteri know not the knife, the scissors, cæreseur or pessary, also get well. This is certainly great comfort to the ordinary practitioner, who has a healthy fear of disturbing peritoneal coverings, of poking pessaries into the bladder, of mistaking the uterus for the ovary, and of any of the other trivial accidents which

occasionally happen in the higher walks of gynecology. The fact is, that the desire to cut, twist, burn, amputate, electrolyze, and pessarize the uterus has amounted almost to a mania. The aspiring gynecologist who has been unable to devise a new operation, invent a speculum, or modify an old one, has been compelled to infuse his energies either into a new cauterizing iron, a novel back-action curette, or a manifold self-acting elevator. If, perhaps, he fails in every other way in encouraging operative procedure, he gives a new and important twist to a pessary, establishes a principle, and makes a reputation. But if the time has come for a change of opinion, if the worst must come to the worst, advocates of the new doctrine can do no more than arrest the study of surgical statistics, and, as a possible consequence, create a corner in uterine pathology. In any event we are willing to give the uterus one more chance.

### INDEPENDENT EXAMINING BOARDS.

WE have been so thoroughly impressed with the necessity for the independent examination of candidates for graduation in medicine, that we gladly call attention to the subject at this time, in view of its prospective discussion at the next meeting of the State Society. At the session last year, a resolution was passed to the effect that a committee of six examiners be appointed by the President of the Society to attend the annual examination of such colleges as might request the service, and determine the qualifications of the graduates. After some discussion the resolution was accepted, and referred to a committee of which Prof. Moore is chairman, and which committee is expected to report on the second day of the coming meeting.

The conservative element of this proposition will commend itself to the thoughtful consideration of all interested in the advance of medical education, not only in this, but in the other States. We cannot doubt that the resolution will find favor with the Society. There is nothing compulsory in the measure; any college is free to accept the board or not, as it may choose. The failure to do so, however, would arouse the suspicion that the methods of examination are not above suspicion. One or two of the leading colleges in this city have agreed to the proposed plan, and have expressed a willingness to submit to the fullest possible censorship of the examining room, in the belief that the more that is known of their methods the better satisfied will be the profession of their standard. It is not absolutely necessary that the committee take active part in the examination, in fact, for obvious reasons, it might be much better that they should not. But all the examinations should take place in their presence, and they should satisfy themselves of the fitness of each candidate and report accordingly to the Society. In cases of doubt it certainly would be the policy of the college to satisfy the

board rather than run the risk of an adverse report. If the board act as invited and therefore privileged inspectors, they need not necessarily have a vote with the faculty, yet if the colleges agree to give them that privilege it will be one of pure courtesy. Aside from guaranteeing fair play in final examination, it will help to establish a uniform standard throughout the State. It is so positively against the interest of the colleges themselves to oppose the measure, that there does not seem to be a doubt as to their action.

#### THE NURSE TRAINING SCHOOLS.

THE success of the Training School for Nurses of this city is everything which its most earnest advocates could desire. During the past year its work has increased, from the care of nine wards with one hundred and sixty beds and thirty-one nurses, to twelve wards with one hundred and nine-two beds and fifty nurses. Aside from this, there are ten nurses detailed for private service, which are regularly employed in visiting the sick poor in connection with the New York City Mission. In connection with the benefits which trained nursing can confer upon the sick, no one can be too enthusiastic in urging its claims to public and professional consideration. The recent appropriation of the old building of the Medical Department of the University to the purposes of this Association is a step in the direction of still more hopeful services to the sick. With the increased facilities for instruction and with the conveniences of management which a commodious and well-arranged building affords, the managers of the school have placed in their hands resources almost unequalled in any other city. The demand for these trained nurses is increasing, and must continue to do so, as experience teaches us more and more the value of their labors.

#### THE CARE OF THE CHILDREN.

A WRITER in a recent issue of the *Times* calls public attention to a new scheme for the care of the poor children during the present summer season. Although the St. John's Guild deserves a great deal of credit for establishing its summer excursions for poor infants, we agree with the writer that the ultimate results of the plan have fallen far short of the expectations of its friends. We early called attention to the absurdity of crowding together large numbers of children for the sake of a few hours' sail through the Bay or up and down our rivers. The fatigue of travel to and from the boat, the excitement and discomfort while aboard, and all the other drawbacks of an infant picnic, more than counterbalanced any good which might be obtained from a few hours' breathing of fresh sea air. The desire to make these excursions popular naturally prompted a disposition to overdo the matter, and the more children who could be counted as passengers the better. From a purely sanitary meas-

ure at the start, it became a simple business speculation, which culminated in the building of the so-called hospital barge, and which is nothing more than a well-appointed excursion boat. We are not informed whether the managers of the Guild intend to keep up these daily excursions, but as there is little doubt of it, there will not be much prospect of sanitary improvement. As we have often remarked on previous occasions, the only way to utilize profitably the good intentions of the Guild is to make the barge a floating hospital proper, to anchor it in some convenient and accessible place in the river or Bay, and allow patients to remain upon it a week or more at a time. But as this would probably interfere with its success, as a so-called charitable enterprise, we have no hopes of its being carried into effect. The writer in the *Times* has the same object in view, but he applies it to a different end, which is the construction of cheap temporary encampments for the children out of town. These habitations he intends not only for the sick children of the poor, but for the well children of the tenement house population. The idea is eminently practical, and commends itself to the charitable, to whom he appeals for aid. There is not the slightest doubt in our mind that such a plan, if properly carried out, would materially lessen the infant mortality in the densely crowded portions of our city during the summer months.

#### THE SHOP-GIRL QUESTION.

THE shop-girl question has of late given rise to a good deal of discussion in the daily papers. Some years ago attention was drawn in Liverpool, England, to the hardships of female clerks, who were compelled to stand the greater part of the day, whether they were busy with customers or not. A society of influential ladies undertook to remedy the evil, but, aside from arousing a temporary public indignation against shopkeepers in general, nothing was accomplished. There is, however, some promise that something will be done in this city, judging from the widespread interest manifested on behalf of the sufferers. There does not seem to be any argument in favor of the girl standing, when not engaged with customers, that would not hold equally good when sitting. Such is certainly the case if we take no more than a purely business view of the matter. But if we go beyond this and view the situation from a strictly hygienic point, there is no end of argument against the evil. In fact, so one-sided are they that it seems almost presumptuous on the part of the shopkeepers to offer any other than purely business reasons for their cause. The ordinary male clerk finds, not infrequently, his endurance taxed to the utmost by this submission to the standing discipline, but what to him is simple fatigue becomes downright cruelty to the delicate girl, especially during the catamenial period. In respect to the care of themselves which they should exercise at those

times, they are on a par with their more fortunate sisters. It is no reason that business should be neglected on account of the physical disability of the employes, but, on the other hand, health should not be sacrificed to unnecessary rigor in enforcing rules. The friends of the new movement have the strongest arguments on their side, and it is to be hoped that they will continue their good work until some definite and practical results are obtained.

#### THE NEXT MEETING OF THE STATE SOCIETY.

In another column we publish the order of business of the coming meeting of the Medical Society of this State. We call attention to the fact more particularly for the purpose of inviting other similar organizations to follow the example. By this means the members who wish to take part in discussions have the opportunity of preparing themselves beforehand.

### Reports of Societies.

#### NEW YORK PATHOLOGICAL SOCIETY.

*Stated Meeting, April 25, 1877.*

DR. E. G. JANEWAY, PRESIDENT, IN THE CHAIR.

##### MAMMARY TUMOR—THE RETURN OF SARCOMATA.

DR. E. H. M. SELL presented a mammary gland which had been removed from a patient *æt.* 55 years and 8 months. The breast contained a new growth which was first noticed about seven weeks previously, when it was about the size of a common marble. There was no history of hereditary taint upon either side, and no history of injury. There was no enlargement of the axillary glands. At the time of removal the tumor was about two and a half inches in diameter. The Doctor supposed it to be scirrhus.

DR. BEVERLEY ROBINSON regarded it as a very rapid growth for scirrhus.

THE PRESIDENT remarked that the tumor had the appearance of a sarcoma, small spindle-celled perhaps, which has a rapid growth.

DR. SELL.—So much the better for the patient.

THE PRESIDENT.—Not so certain, for sarcomatous tumors return, and are very commonly troublesome affairs.

DR. BRIDDON remarked that the larger majority of sarcomas of the breast returned much more quickly than pure scirrhus.

The specimen was referred to the Committee on Microscopy.

DR. BEVERLEY ROBINSON presented specimens of the following:

CATARRHIAL PHTHISIS—SECONDARY TUBERCULIZATION OF LUNGS, PLEURA, KIDNEYS, AND PERITONEUM—CHRONIC PLEURISY (LEFT)—ACUTE PERICARDITIS—ACUTE CATARRHIAL PNEUMONIA—FATTY LIVER—CHRONIC ULCERATIONS OF SMALL INTESTINE.

P. H., *æt.* 22; native of Ireland; was admitted to Charity Hospital on March 12th of this year.

On admission he was weak and emaciated, and complained of pain in left side and persistent cough. Father still living; mother died some years ago, cause unknown. Patient says he has been a hard drinker

during past six years. He has been annoyed for several months with an abundant purulent expectoration, and has at present considerable difficulty in breathing. Several years ago he had a hard chancre, and since that time has had cutaneous manifestations of constitutional syphilis. Macule are now visible upon lower extremities. No actual bony lesions, nor any nocturnal pains beyond those which are constant in thoracic region. His pulse and respiration are accelerated, and there is considerable elevation of temperature. His cheeks are flushed, especially the left. Several nerve symptoms are present, indicating considerable depression of vital forces, or anterior habits of intemperance, such as uncertain and irregular movements in the use of the hands, hesitation and stammering in speech, accompanied by fibrillary contractions of tongue, lips, etc.

The brain is lucid, and there are no symptoms of paralysis; voice is very hoarse. On percussion of chest, moderate dulness is found under clavicles on both sides. In these regions are also found subcrepitant râles in abundance. In posterior portion of chest there is moderate dulness on the right side. On the left side, dulness is more marked still, especially in lower half of chest, where it is nearly absolute. At this level there is loss of vocal fremitus, and the breathing is muffled and distant. At upper third of left lung, bronchial breathing and increased vocal fremitus are readily appreciated. Throughout this space, then, there is no doubt about the existence of a consolidated condition of lung-tissue, due probably to a catarrhal pneumonic process. Upon puncture of the lower portion of left pleural cavity with the needle (No. 2) of aspirator, serous fluid was found, and about eighteen ounces were withdrawn. After the removal of fluid from the chest, patient's condition was somewhat ameliorated for about two weeks, when he again began to fail. Mucous râles in increasing numbers were heard distinctly everywhere throughout both sides of chest; cough and expectoration became still more distressing; a fresh pneumonic process was set up in the lower portion of the right lung, to which patient finally succumbed. On the day preceding death, patient's larynx was examined with the laryngeal mirror, but owing to great local irritability and excessive dyspnoea, nothing further was accurately determined beyond the fact that the hoarseness was due to a catarrhal or phthisical process, and *not* to a syphilitic one. The cords could not be seen, it is true, but the epiglottis and upper orifice of the larynx were distinctly observed. There was no œdema or swelling of these parts; the epiglottis was pale and intact, as also the faucial region. Much frothy mucus was present in the larynx. These signs, taken in connection with the other symptoms of disease noted in this history, were deemed sufficient to eliminate laryngitis of syphilitic nature.

Autopsy was made by Dr. E. A. Maxwell, 21½ hours after death. Rigor mortis present. Body medium size, fairly nourished.

*Head.*—Brain normal.

*Larynx.*—Both vocal cords show about their middle portion, at upper and rim borders, small longitudinal ulcerations, while the rim of vocal cord is thickened. At posterior commissure of each is an irregular spot, where mucous membrane is eroded; interior mucous membrane is congested.

*Trachea.*—Mucous membrane congested; tracheal glands normal.

*Thorax.*—*Lungs.*—Right pleural cavity almost obliterated by old adhesions; left pleural cavity filled with brownish, opaque fluid.

**Left Lung.**—Compressed against spinal column, and firmly adherent to intercostal pleura and that covering diaphragm; surface of lung anterior to adhesion is covered with pseudo-membranes about one-quarter of an inch in thickness; thick hemorrhages at various points. At apex of left lung a cluster of small cavities, the largest of size of pigeon's egg; at parts of upper two-thirds of lung occasionally a small cavity found, and side of this lung studded with yellowish granulations, singly and in clusters; moderate amount of fibrous induration.

**Right Lung.**—Upper lobe consolidated at anterior margin by fibrous indurations; more margin than in opposite lung; the same yellowish and gray nodules; few small cavities. Many of smaller bronchi show ulcerated mucous membrane. In middle and lower lobe, and scattered here and there, miliary, semi-transparent granulations; lower lobe throughout partially consolidated by acute pneumonia (catarrhal), showing red and gray stages.

**Pleura.**—In œdematous pseudo-membranous cavity of pulmonary pleura are scattered miliary granulations.

**Heart.**—Pericardium contained about four and a half ounces of dark-colored fluid; both visceral and seral layers show fibrinous exudations, containing emorrhages; on looking for tubercles, found two only (questionable); walls and valves normal.

**Peritoneal Cavity.**—Contains one and a half pints of fluid, clear, straw-colored; surface of peritoneum shows the characteristic miliary, semi-transparent grayish granulations, singly and in clusters.

**Liver.**—Shows a few granulations beneath capsule, so localized perihepatitis; throughout parenchyma, one or two granulations, are some fatty intralobular congestions.

**Spleen.**—Enlarged; perisplenitis; softened.

**Kidneys.**—Surface and throughout parenchyma, a few scattered tubercles are found, medium size. Capsule slightly adherent; moderate atrophy of columns, tubules and pyramids; the latter spread out; Malpighian bodies prominent and shining.

**Stomach.**—Normal.

**Intestines.**—Small, shows congested mucous membrane; lower one-third shows scattered phthical ulcerations; at ileo-cœcal valve are several ulcerations which have partially destroyed the valve. In large intestine, occasionally an enlarged solitary gland; mesenteric glands are enlarged.

DR. ROBINSON raised the question whether such tubercular process could fairly be regarded as secondary in the phthical conditions. He was inclined to the opinion that the catarrhal phthisis and the tubercular process were developed at the same time.

THE PRESIDENT was of the opinion that in many cases there would be found an older and also a more recent process. For instance, not infrequently, there is found in the lungs places which gave the appearance of a lesion that had lasted for some time; a place in which perhaps had advanced to the cheesy state, and such a place, perhaps upon the pleura over it, finds more recent grayish nodules; those similar appearance might also be found in the liver and in the kidneys, usually more opaque, and over, in those organs, and perhaps in the meninges of the brain. The appearance under those circumstances would point to a more recent lesion, as far as the new growth was concerned.

Experimental pathology would point to the same conclusion—namely, that those gray granulations of more recent formation than the older process, are not rapidity with which they could run their course

was seen in acute cases, when the entire duration of the disease was no more perhaps than a few weeks or months. The phthical process in the case presented had probably lasted a much longer period of time.

#### FRACTURE OF NEEDLE WHILE MAKING EXPLORATIVE PUNCTURE INTO THE PLEURAL CAVITY.

In this connection THE PRESIDENT referred to three cases in which the needle used for making an explorative puncture into the pleural cavity had been broken by the sudden movement of the patient as it was thrust in. One case occurred in his own service in Bellevue Hospital, one in Roosevelt Hospital, and one in Charity Hospital.

In neither instance had the portion of needle left in the pleural sac given rise to unfavorable symptoms. The three cases came to his knowledge within one month, and showed the liability to an unpleasant accident, which had not occurred to him before, while performing this simple operation, and of which he had no recollection of having seen anything published.

DR. ROBINSON referred to a case in which the same accident occurred, but no unpleasant symptoms followed.

#### BILIARY CALCULUS IN THE CYSTIC DUCT—PAIN AS A SYMPTOM.

DR. AUSTIN FLINT, Sr., in behalf of Dr. Ellsworth Eliot, presented a cystic duct containing a biliary calculus; also a biliary calculus which had been removed from the gall bladder of the same patient. The latter was perfectly round, and presented a variegated surface. The gall bladder was somewhat diminished in size, and contained a small quantity of transparent gelatinous liquid. The chief interest in the case was the fact that there were no symptoms during life which indicated any trouble with the gall bladder or its duct.

The patient had been ill for a year or more, had chronic Bright's disease, and dilatation of the heart, and died suddenly in the act of getting out of bed. The case illustrated the fact that a calculus in the cystic duct did not always give rise to pain.

DR. BRIDGES remarked that gall stones were not painful when stationary, and gave rise to pain only when movable.

DR. FLINT remarked that if stationary they gave rise to pain when situated in the common duct.

DR. BRIDGES remarked that we would expect them to be accompanied with pain when situated in the common duct, though they might be stationary, for the pain would be caused by the pressure from behind.

DR. FLINT remarked he had always supposed, in certain cases of hepatic colic in which careful examination failed to reveal the presence of gall stones in the feces, that the pain was due to the passage of a calculus into the cystic duct, and instead of going on through the duct had receded into the gall bladder.

DR. E. MASON remarked that in Reynolds's System of Medicine, one author spoke of cases in which gall stones became impacted in the cystic duct without giving rise to pain.

THE PRESIDENT remarked that he had been struck by the fact that many persons suffered severely from a degree of pain of which others made no complaint at all. He had noticed the fact, especially in connection with the passage of biliary calculi.

#### MORBUS COXARII.

DR. LEWIS A. SAYRE presented the remaining portion of the head and neck of the femur removed in his sixty-ninth excision of the hip-joint.

The patient's name was Geo. W. Smith, aged 19, and a resident of Pittsburg, Pa. He was a remarkably healthy boy, and was born of healthy parents. When between 11 and 12 years of age he injured his left hip-joint by trying to lift his leg upon the top of the banister in the porch, which was too high for him to reach. He was treated for some time for rheumatism. After some months the attending physician suspected hip disease, and applied "Sayre's" splint, which was worn for five months, when he was considered able to be without it. After some time the disease redeveloped, in consequence of over-exertion in running after the cars. The splint was reapplied and worn for seven months, when he was again considered cured, and it was again removed. He seemed to be in perfect health for eleven months, when the disease again redeveloped after severe playing at a game of foot-ball. He was then 16 years of age. From that time the disease had steadily developed. Extensive abscesses had formed around the hip, discharging freely for the past two years. In September, 1876, an extensive swelling occurred in left iliac region, accompanied by acute peritonitis, and terminating in an abscess, which opened near the pubis, above Poupert's ligament. This had continued to discharge very copiously during the winter, and he became so much exhausted that death seemed inevitable. Dr. Sayre was telegraphed to see him, at the request of Dr. Benham. He arrived in Pittsburg on the 12th of April, 1877, and operated the same day, assisted by Drs. Benham, Bruce, and McDonald, all of Pittsburg. The boy was perfectly anaesthetized with ether by Dr. Benham, and was not conscious that Dr. Sayre had been in Pittsburg until some hours after the operation was performed.

The operation was performed in the usual manner, and about four inches of the femur removed. The head of the bone was so firmly impacted in the perforation through the acetabulum, that an immense amount of force was required to dislodge it, and, when removed, a large quantity of pus gushed through the opening. The femur measured at the trochanter minor six and a half inches in circumference: the enlargement being due to rarefying osteitis. The circumference of the neck was four inches.

The wound was cleansed and dressed in the usual manner, and the patient placed in the "wire breeches."

*April 24th.*—The case was progressing very favorably. The points of interest in the case were: 1, that it was distinctly of traumatic origin; 2, that relapses might occur after an apparent cure of morbus coxarius affecting an originally healthy joint, thus showing that care should be exercised and protection given against injuries for a long time after an apparently perfect cure of the disease.

Dr. GIBNEY inquired whether the bone was removed at a point below the rarefying osteitis, and was answered in the affirmative.

#### CANCER OF THE BLADDER AND RECTUM.

Dr. E. MASON presented the bladder and rectum taken from a patient who died in Roosevelt Hospital, April 15, 1877. He was forty-five years of age, and gave a good family history. He was admitted to the hospital in December, 1876. Four months before admission he was seized with an attack of cold, as he called it, and, after the chill had passed off, noticed for the first time that he had difficulty in passing his water. From that time on, he suffered from difficult micturition, and gave all the symptoms of stone in the bladder. When he came under Dr. Mason's charge, in February, he was considerably emaciated, and was

suffering from great pain in the bladder and lower portion of the rectum. On introducing a sound into the bladder it was found to be contracted and the walls very much roughened. As the finger was passed into the rectum it came in contact with an indurated mass in the region of the prostate gland, and the posterior wall of the bowel was also somewhat implicated. The inguinal and lumbar glands were enlarged.

*Diagnosis.*—Cancer of the prostate and base of the bladder. The urine was drawn by means of a catheter during the last month of the patient's life. At autopsy the bladder was found to be the seat of cancerous disease, and the new growth had also involved the rectum. The new growth doubtless had its starting-point in the bladder, and could be seen as four distinct nodules. The prostate was not infiltrated with cancerous growth. There were secondary deposit in the liver.

#### GENERAL CARDIAC HYPERTROPHY AND DILATATION.

Dr. A. L. LOOMIS presented the heart and other organs removed from a man, *et.* 26 years, a saddler by occupation, who was admitted to the Mt. Sinai Hospital, April 1, 1877. The patient gave no history of hereditary or acquired taint, and affirmed upon close questioning that he had been perfectly well up to four weeks before admission. He had never had rheumatism or syphilis. Four weeks before admission, the patient was seized rather suddenly with a severe pain in the left side, just under the nipple, and it also extended down the left arm. He stated that within two or three days following the attack, his feet began to swell. The swelling increased, the pain became more severe, he had some difficulty in breathing, and was unable to lie down. When admitted to the hospital he was extremely cyanosed, his respiration was laboring and 40 to the minute; his pulse 120, and temperature  $98\frac{1}{2}^{\circ}$  F. His countenance was extremely anxious. There was no irregularity of pulse, nor did it intermit. The urine contained a small amount of albumen, but no casts. Physical examination showed feeble respiration at the base of both lungs, with subcrepitant rales and dulness upon percussion. Respiration over the remaining portion of the lungs was normal. The apex beat was diffused, extended to the left of the nipple about one inch, and an inch below the normal position. Percussion over the region of the heart showed an increased area of dulness in all directions except upward.

Upon auscultation a loud presystolic murmur was heard at the apex and over the entire precordial space.

A less distinct and less intense systolic murmur was heard with greatest intensity about the median line, was conveyed to the right, and was not heard beyond the apex.

A systolic murmur was heard at the base of the heart, but it was not conveyed along the course of the arteries. There was a distinct epigastric and jugular pulsation.

*Diagnosis.*—General cardiac hypertrophy and dilatation; presystolic or mitral stenosis; tricuspid regurgitation; pulmonary oedema and fluid in the pleural cavities.

He was placed upon digitalis, and his condition improved very rapidly. The dyspnoea was relieved, the signs of pulmonary oedema disappeared, the oedema of the feet began to be removed, the fluid present in the abdominal cavity at the time of admission entirely disappeared; he was able to lie down; his pulse became less rapid, never falling below 100, however; his appetite returned, although at no time was he able

to take any quantity of food without causing nausea. The improvement continued for a week or ten days, when suddenly all the signs of cyanosis reappeared, his respiration became labored, evidences of pulmonary œdema developed, fluid returned to the abdominal cavity, œdema of the feet and lower extremities increased very rapidly, and the patient died on the 10th of April in a state of unconsciousness.

**AUTOPSY.**—*Brain*—Ventricles contained a considerable quantity of serum, and there was also considerable serous effusion into the subarachnoid space.

*Lungs*.—Old pleuritic adhesions, evidences of congestion, and œdema at the lower portion of both; pigmentation, and considerable fluid in both pleural cavities.

In the upper lobe of the right lung there was found recent hemorrhagic infarction; no infarctions elsewhere, either in the lungs or other organs.

*Kidneys*.—Indurated and congested.

*Liver*.—Increased in size and hard.

There were evidences also of gastric and intestinal atarrh.

*Heart*.—Very much increased in size in every direction; left ventricle dilated and hypertrophied; thickening and adhesion of the aortic valves, yet no insufficiency. There was thickening, adhesion, and retraction of the mitral valves; the mitral orifice was diminished so as to scarcely admit two fingers; chordæ tendinæ shortened, and there was a large amount of new connective tissue about the base of the valves.

The walls of the left auricle were thickened and its cavity dilated. The right ventricle was very much dilated, its walls were thickened, and the tricuspid valves were insufficient. There were some vegetations upon the contracted portion of the mitral valves.

It was a well-marked specimen of general cardiac hypertrophy and dilatation.

The points of interest in the case were, *first*, its history. The patient, following a trade which had not required very much active exercise, had gone on without suffering from any symptoms which would lead to the suspicion of cardiac disease until four weeks previous to his admission to the hospital. His symptoms then developed suddenly, and became severe very soon after their first appearance.

*Second*. From the appearance of the mitral valves we would suppose that there must have been mitral regurgitation during life, and yet the murmur was not heard to the left of the apex, nor was it heard in the usual position behind.

Dr. Loomis was of the opinion, from observations which he had made, that when mitral stenosis accompanied mitral regurgitation, the regurgitant murmur was frequently absent.

*Third*. From the appearance of the aortic valves it would seem that there must have been an obstruction to the outgoing current during life, and yet from more than one examination he was not able to detect a murmur much beyond the base of the heart, and a murmur was not heard at the junction of the second rib with the sternum upon the right side, and no murmur was heard in the carotid. The diagnosis of aortic obstruction was not made.

Dr. FLINT asked Dr. Loomis what he attributed the sudden occurrence of symptoms?

Dr. LOOMIS replied that he supposed it to be due to failure of the right heart.

Dr. FLINT remarked he had often observed that disease of the heart had existed for some time without giving rise to any special symptoms, when all at once severe symptoms were developed without apparent cause.

Dr. ROBINSON mentioned that it was rare, with vegetations upon the valves of the heart, to have infarctions only in the lungs.

The PRESIDENT remarked he had noticed that valves which appeared as though they would admit of regurgitation had not done so when carefully tried with the water-test.

Dr. LOOMIS remarked that the water-test was applied to the mitral valve in his case as soon as the heart was removed, and it was found that regurgitation took place.

The PRESIDENT remarked that the aortic valves looked as though they might allow leakage.

Dr. LOOMIS remarked that they also were tested with water when the heart was first removed, and did not allow of regurgitation.

The PRESIDENT remarked that the left heart, in comparison, did not seem to be much hypertrophied, although the cavity of the ventricle was dilated.

If the man died in diastole the real would not be so much as the apparent dilatation.

Dr. LOOMIS remarked that he was unable to say whether death occurred during diastole or systole. He had measured the cavities, however, and found that they exceeded the normal dimensions by considerable.

Dr. LOOMIS suggested the question whether in mitral obstruction there was ever present a condition of the auricle that prevented free regurgitation at the mitral orifice?

The PRESIDENT referred to cases of mitral stenosis in which the murmur was heard under the angle of the scapula.

Dr. FLINT inquired with reference to the subsequent changes in the infarction had the patient lived.

The PRESIDENT replied that it would probably have become a cicatricial nodule with pigmentation.

#### ANEURISM OF THE MIDDLE CEREBRAL ARTERY.

The PRESIDENT presented a specimen of aneurism of one of the small branches of the middle cerebral artery, situated just after the vessel penetrated the anterior perforating space, and leading to large hemorrhage into the corpus striatum, brain, ventricles, and at the base, causing death four hours after its occurrence.

There was hypertrophy of the left ventricle of the heart, with chronic Bright's disease, but no marked degeneration of cerebral arteries.

## Correspondence.

### THE PLASTER-OF-PARIS JACKET AND A QUESTION OF PRIORITY.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—I have read the communications from time to time in your excellent journal, on the merits of the plaster-of-Paris dressing in angular curvature of the spine; also of the same mode of dressing used in rotary lateral curvature.

I have received additional instruction from reading the late communication in THE MEDICAL RECORD from Dr. Benj. Lee.

Dr. Sayre deserves great thanks from the profession at large, for thus bringing the subject so prominently before it, both in his excellent work on Orthopædic Surgery, and in his papers read before different societies, and published.

My object in this communication, however, is to

record the history of a case of angular curvature, where the plaster-of-Paris dressing was used, at least *ten months* previous to that of the first case recorded by Dr. Sayre (June 4, 1875). See *N. Y. Med. Journal*, Sept., 1875, p. 243.

It is my purpose, also, to give due credit to a modest and deserving young man, Dr. Joseph Bryan, of Lexington, Ky., late house surgeon of Bellevue Hospital.

During my term as house surgeon of Bellevue Hospital, there was admitted to Ward 30, Second Surgical Division, this patient, with the following history, as written by Dr. Bryan, then my senior assistant.

Let me here state that the original history was always written by the senior assistant in a blank-book, provided by the house surgeon or house physician, as the case might be, and from this the junior assistant copied the history into the hospital record of the division. Consequently, I have in my possession the history of the following case:

Rosanna Brennan, 15, single, New York. Admitted Aug. 8, 1874. Family history not good. Patient's father died in prison; of what, she is ignorant. Mother is perfectly healthy.

Patient has had two brothers and two sisters. Both brothers are dead. One died of either disease of the spine or hip, she does not know which. Patient does not know of what the other brother died.

Of the two sisters, the younger has always been healthy. The elder, about eighteen years old, had a cough which lasted her a long time, but she finally recovered.

Patient herself has always been perfectly healthy until about three months ago, when she began to have pains in the back—the pains more especially in the lumbar region. She applied for relief at the Forty-second Street Hospital, where it was discovered that she had a prominent point, very tender, in the lumbar region of the spine. She also complained of pain extending down her lower extremities. The doctor at Forty-second Street Hospital told her she had disease of the spine, and made and applied a spinal splint. But it did not relieve the pain, and she therefore came to this hospital. On examination, discovered a prominence in the lumbar region, probably the third or fourth lumbar.

Pressure on this prominence gives her intense pain. Patient is hardly able to stand, and says that she suffers a great deal if made to stand long.

While in the standing position, pressure on the shoulders gives her pain.

Patient appears pretty well nourished. Appetite not very good. Says she does not sleep very well at night.

Dr. Mott, visiting surgeon, saw patient, and ordered her to have a seton put in her back near to point of tenderness.

Aug. 16, 1874.—To-day put an issue-peg in patient's back, near the point of prominence, as ordered by Dr. Mott, and applied her spinal brace made by Dr. Knight's direction at the Forty-second Street Hospital. Patient complained of pain during the afternoon, and compelled to go to bed again.

Aug. 21, 1874.—Applied her splint again this morning, but she complained so much of pain that we had to remove it again. Determined to apply a plaster splint.

Aug. 22, 1874.—To-day applied plaster-of-Paris splint, extending from axilla to one inch above the trochanter major, so as, if possible, to prevent any motion in the lumbar spine.

Aug. 24, 1874.—Had a fenestrum cut over the point of prominence, so as to be able to dress the issue

daily. Patient feels perfectly comfortable with her splint on. Is to-day up and about the ward. General condition good.

Aug. 31, 1874.—Since the application of plaster-of-Paris splint, patient has done remarkably well. Suffers no pain, and is able to be up and about the ward all day. General health excellent. Takes cod-liver oil and iron, and a generous diet.

Sept. 10, 1874.—Since date of last note, patient has been up and about the ward all the time. She, however, complains of some pains in her legs and upper extremities, but do not think they are referable to her spinal disease. The issue is dressed daily, and discharges considerable. Patient's general condition excellent.

Sept. 17, 1874.—Patient still continues to do remarkably well. Issue discharges considerable, and is dressed by the nurse daily.

Dr. Bates and I assisted Dr. Bryan in applying the apparatus. Dr. B. had requested me to allow him to use the plaster-of-Paris dressing as an experiment.

As Dr. Bryan has not given in the history of this case the mode of applying the splint, I will add it now. A neat woollen jacket was prepared by the "trained nurse," Miss Wright, with whom we were all in love, and whom the doctor afterwards married and took to his home in Kentucky.

Compound or dislocation pulleys were attached to the water-pipes, which run close to the ceiling in of Ward 30. To the pulleys was attached, from its centre, a pine stick two or two and a half feet long from the extremities of which slings passed under the arms at the axilla. Thus was the patient suspended her toes merely touching the floor.

Within a day or so her picture was taken, posteriorly, so as to show the fenestrum, by Mr. O. C. Mason, the hospital photographer, on a requisition signed by one of the visiting surgeons, and myself, house surgeon. I have her picture at present in my office, and Mr. Mason should have the negative. Some doubt has been expressed as to the justice of Dr. Bryan's claim to originality or priority, with this history, from the original history book, may throw some light upon.

You will observe that the same mode of extension, with the same appliance, was used as in the cases of Dr. Sayre.

He also used the punctured tin strips as stays in the jacket. Dr. Bryan did not use extension from the neck, which is a valuable addition in the application of this splint. I would publicly thank Dr. Sayre for additional hints in the treatment, such as extension of the neck, and also the benefit to be derived by day self-suspension in cases of rotary lateral curvature, as recommended by Dr. Benj. Lee. I can see, in a case at present under my care, great benefit from this day exercise.

W. C. SHAW, M.D.

135 WYLIE AVE., PITTSBURG, May 29, 1877.

## HISTORICAL NOTE ON MODERN OPTHALMOSCOPES.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—The perfecting of any mathematical or optical instrument which pertains directly to the practice of medicine, and which, by its perfection, tends to narrow the boundaries between medicine as an art, and medicine as a science, has, or should have, an interest to the whole profession; and more to the general practitioner than to the specialist, since it is the former rather than the latter who invariably profits a

greater degree from simplicity of form and absence of technicalities. There is, perhaps, no instrument in modern medicine in which the improvement in construction has more clearly demonstrated its value, or more extended its use than the ophthalmoscope. To such a degree is this true that the very method of examination formerly but rarely used on account of its difficulty, has now become universal, and this mainly, not entirely, through the improvements made during the last seven or eight years.

For this reason it appears to the writer that credit should be given to all of those who have aided even to the slightest degree in this work, and it is in justice to others as well as to myself, and with the desire of correcting some erroneous impressions, that the following remarks of an historical character are offered. And, perhaps, the simplest way of doing this is by applying briefly to some assertions which have been made from time to time, and which would not seem to be strictly in accordance with the facts of the case.

I was informed that Dr. Knapp had stated, in a lecture at the College of Physicians and Surgeons, as he has in substance in other places, that the instrument now sold under my name was a modification of an ophthalmoscope invented by him, and that this modification consisted of but "one unimportant particular." The evident, indeed the only meaning of this, that I took from his instrument all the important principles, and added only one which was not important. It is against this allegation, which has been repeated to me from many sources, that I now wish to reply. And I should like to say at the outset, that it is not so much against the actual statement that my remarks are directed, as it is against what the words in substance imply. For it may be that Dr. Knapp never made the statement precisely as it stands above. About this there may well be a doubt, but of the impression left on the minds of those who have heard these statements and who have repeated them to me on various occasions, there can be no doubt whatever. This it is which I feel needs some explanation in my part.

In 1868, I began to make modifications of the ophthalmoscope. Up to this time it had been considered operative, with instruments designed for the use of the upright image and determination of the errors of refraction, to place the glasses in such a manner that the axis of the glass should coincide with the axis of vision of the observer's eye. This was deemed all essential in order to avoid distortion of the image from astigmatism. To attain this end it was necessary to have the glasses placed at a considerable distance from the mirror, which was then set at a considerable angle to the plane of the surface of the glass. From this it resulted that the eye of the observer, in the instruments used for this purpose, such as Jaeger's and Schiwwag's, was nearly, if not quite, one inch from the eye in the mirror.

Owing to this method of construction, with its attending disadvantages of reduction in field and illumination, and its inherent difficulties of manipulation, the use of the upright image, the most beautiful and comprehensive method of examining the eye, was limited to a few enthusiastic experts, and even with them to a restricted degree. From the fact that a small oblique opening, placed immediately in front of a lens, preserves the clearness of the image even when the lens is rotated on an axis, it occurred to the writer that a great increase in brilliancy of the image and extent of field could be obtained with a disproportionately small amount of astigmatism, even with the stronger glasses, by placing these directly against

the mirror hole, all the brass work being made as thin and as much bevelled as possible to avoid reflections.

This was called a modification of Rekos's "disks," but in point of fact differed considerably from it. For the contrivance of Rekos's consisted of a series of three disks placed one behind the other at a considerable distance from the mirror and on a different plane from it. It possessed all the disadvantages described above, and to avoid which was the sole aim of my "modification."

Within a few months after the first published modification appeared (1869), a second was introduced by the writer, consisting of a single disk which rotated round a central axis. Three sizes of the instrument were made in rapid succession, one containing nine, one thirteen, and one sixteen glasses. And the number of these might have been increased at the option of any one, the limits only being set by the size of the glass or the diameter of the disk.

Numerous modifications of these instruments followed at once, not only in this country, but abroad. Among the later ones was an instrument contrived by Dr. Knapp in 1873,\* four years after my first modification, and three years after the one with a single disk. This was an ophthalmoscope with two disks. Of all unhappy optical contrivances this would certainly seem to be the unhappiest, violating, as it does, most, if not all, the necessary optical and mechanical principles which should govern the construction of an ophthalmoscope. Two centres of motion were used, where one would do, thus throwing one disk above the brow and making the centre of rotation come, not in the axis of the handle, but eccentrically at the edge of the disk over the brow. Owing to this, the rotation of the mirror sufficient for an ordinary examination carried the glasses to a considerable distance from the eye of the observer, increasing the astigmatism and decreasing the field and illumination. Moreover, as one disk came above the brow and in immediate contact with the skin of the forehead, it was absolutely essential that the glasses should be covered.†

Led by the failure of this instrument, or as Dr. Knapp puts it, "by the teaching of ophthalmoscopy," he produced, in 1874, what he styles, not a modification of the ophthalmoscope, but a "new ophthalmoscope with a single disk," and as the fact of my infringement rests on this particular instrument, it is material to show in what this claim to novelty consists. As an earnest of originality, Dr. Knapp begins the description of his new instrument with the declaration that "a series of auxiliary lenses, as used by Loring and others, appearing to suffice to the student and practitioner in ophthalmology, I had that series inserted into one disk." That is to say, he took, as the foundation of his instrument, the identical series of glasses which I had determined upon after some considerable trouble. He employed a single disk, "leaving the mechanism of fixation, rotation, and covering of the disk the same as in the compound instrument." Now it happens the fixation and rotation were in every essential precisely the same that I had employed some three years before in my ophthalmoscope with a single disk; that is to say, the disk was fixed directly against, or as Dr. Knapp has it in his phraseology, "under the

\* Trans. Amer. Ophth. Soc., July, 1873.

† Had I been aware that Dr. Knapp was working in this direction, it would have given me pleasure to have furnished him with the idea of a combination instrument, which I had long discarded, and the model of which I showed at the meeting of the Academy of Medicine at which Dr. Knapp presented his instrument. The ophthalmoscope alluded to, although it had all the faults inherent with every combination instrument, was at least constructed on correct optical and mechanical principles.

‡ Archiv of Ophthalmology and Otolaryngology, vol. iv., No. 1, 1874.

hole in the mirror," and rotated round a central pivot held in its place by a screw. When first constructed, the bottoms of the glasses were covered, the disk being held in its position by a thumb-screw. To clean this surface of the glasses the disk had to be removed. To simplify the instrument still further the back was afterward cut away so that both surfaces of the glasses could be cleaned without removing the screw. The essential difference between Dr. Knapp's instrument with a single disk and mine, was that it simply contained more glasses, and on this principle every additional glass could be claimed by its author to constitute a new ophthalmoscope. But even this arrangement was not an original idea of Dr. Knapp's, for Cohn, of Breslau, had done precisely the same thing two years before Dr. Knapp's instrument appeared.\* That this was known to Dr. Knapp, we learn from his own statement in an earlier paper, in which he alludes to "Cohn's modification, in which he puts all the glasses of Loring's three disks into one large disk."

Dr. Cohn, with what would appear to be, in the light of subsequent events, a superfluous piece of magnanimity, did me the honor of describing this instrument as a modification of my own. Dr. Knapp, however, reduces the size of the glasses, and we have not a modification of anything but an entirely "new ophthalmoscope." But even this reduction in the diameter of the glasses was not original with Dr. Knapp, for Wecker, in Paris, had previously constructed an instrument with a single disk with a cover, containing twenty-four glasses, the diameter of which was a little less than four millimetres.

The description of this instrument, with a drawing, arrived in this country before Dr. Knapp presented his double disk ophthalmoscope to the Academy of Medicine, at which meeting he alluded in the discussion to this instrument and expressed his doubt whether the diameter of the glasses could be as small as represented. Two months after this statement his single disk ophthalmoscope, with small glasses, appeared. In 1869, or four years before Dr. Knapp's or Wecker's instrument appeared, I presented to the New York Ophthalmological Society, and at a meeting at which Dr. Knapp was present, an ophthalmoscope, made for me by Zentmayer, in which the diameter of the glasses was less than four millimetres. I afterwards discarded these small glasses for two reasons: first, because the expense in making them at that time was very great, and secondly, because I thought, and still do think, that optically † they are not so good as the larger glasses. I surely thought I had the right to return to them however, without the accusation of any infringement, especially by one who had deliberately taken them from another.

Such being the essential principles of the instrument, we come to the accessories. Dr. Knapp lays great stress on the spring for centring the glasses, and with an air of originality. This contrivance was fully discussed by Dr. Dyer, Mr. Zentmayer, and myself, as early as 1869, and was purposely discarded by me so that the glasses might be decentred to avoid reflections. In 1871,‡ Dr. Strawbridge presented a modification of an ophthalmoscope in which, as it is stated in the Transactions of that year, "the disk rotates behind the opening in the diaphragm, and by

means of a spring catch, each glass as it rotates, is caused to stop exactly behind the centre of the opening." The maker of this instrument was the same who had discussed the idea with me two years before. In 1872 Dr. Oldham presented to the International Ophthalmological Congress, in London, an instrument which he spoke of as a modification of my instrument, in which this spring catch is used. One of these instruments appeared two years and the other one year before either of Dr. Knapp's instruments. I certainly did not get my idea of the spring from Dr. Knapp.

Now, in regard to another accessory, and that the least important one, the protecting cover for the posterior surface of the glasses. Personally I prefer to have this surface exposed, especially when the disk is surrounded by a rim, as we thus get rid of a source of annoying reflections. But, admitting that I took the idea of the cover from Dr. Knapp's instrument, though I had previously discussed its advantages with others—admitting this, it was at least modified in three particulars which did not seem unimportant. First, by making the cover a ring instead of a flat disk we are enabled to see the numbers of the entire series of glasses and turn to any one at once. Secondly, by making the hole oval horizontally we get rid of an annoying reflection which arises from the lateral edges of the hole, and which extends even to this day in Dr. Knapp's instrument, half across the aperture in the mirror. Thirdly, by making the cover swing eccentrically we get rid of all loose screws.

In 1873, Dr. Knapp, when he was trying to introduce his first instrument, with its multitude of useless combinations, observes, "the disks in Loring's ophthalmoscope have not a sufficient number of glasses for the requirements of a careful ophthalmic practitioner."\* One year later, at the meeting of the Ophthalmological Society, at Heidelberg, and before a body of experts, he declares, "the series of glasses in Loring's ophthalmoscope are not only sufficient for practical requirements, but are also suitably chosen."† But this was after he had appropriated the series for his "new ophthalmoscope."

At the same meeting no mention is made of any other modification by me except the original one of three disks, although the one with a single disk had at this time been in use in New York and at Dr. Knapp's clinic for some three years. Dr. Knapp finishes his description of his instrument at Heidelberg by declaring: "Now that Loring has lately changed his ophthalmoscope to make it correspond to the one now presented, no other ophthalmoscopes bought in America" (loc. cit., p. 38). I have no comment to make on this. It will commend itself to those who are at all acquainted with the subject as well to its good taste as its verity.‡

From this statement of facts I may be pardoned for expressing the opinion that it would have appeared to be a little more in accordance with the true state of affairs if Dr. Knapp had said that he had taken the essential principles of what he calls his instrument from mine, and that the one unimportant particular which had been taken from him had been improved.

To Dr. Wadsworth, of Boston, belongs the credit of having introduced the most material improvement in the ophthalmoscope which has been offered in many years—indeed the most original, so far as

\* Zehender, Oct., 1873, p. 307.

† It was to avoid the small glasses on the one hand and the large disk on the other, that my second modification of the single disk containing two concentric rows of glasses was invented. This was presented to the New York Ophthalmological Society in October, 1873.

‡ As a matter of fact, I learn from several of the chief makers, by far a greater number of the cheaper instruments, those with ten and sixteen holes, are sold than any others.

writer knows, since Reute proposed the use of the silvered mirror. This consists of a circular mirror of so small a diameter that it can be set at a sufficient angle to prevent astigmatism and yet be in close proximity to the glasses. This mirror can, however, only be used for the upright image. Acting on this suggestion I have modified the ordinary mirror in such a way that, while it possesses the advantages of Dr. Wadsworth's mirror, it is equally applicable for either the upright or inverted method.

EDWARD G. LORING, M.D.

ARMY NEWS.

*Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army from May 27 to June 2, 1877.*

- GREENLEAF, C. R., Surgeon. Assigned to duty as Post Surgeon at Thomas Barracks, Huntsville, Ala. S. O. 85, Dept. of the Gulf, May 25, 1877.
- KING, Wm. H., Ass't Surgeon. Assigned to duty at Fort Sully, D. T. S. O. 65, Dept. of Dakota, May 26, 1877.
- DICKSON, J. M., Ass't Surgeon. Assigned to duty as Post Surgeon, Jackson Barracks, La. S. O. 82, Dept. of the Gulf, May 22, 1877.
- TORNEY, G. H., Ass't Surgeon. Assigned to temporary duty at Custom House, New Orleans, La. S. O. 85, C. S. Dept. of the Gulf.
- CROMPTON, L. W., Ass't Surgeon. To accompany attalion 3d Inf. to Holly Springs, Miss., and, upon arrival, assigned to duty as Post Surgeon. S. O. 87, S. Dept. of the Gulf.
- TAYLOR, M. E., Ass't Surgeon. To accompany attalion 13th Infy. to Baton Rouge Barracks, La., and, on arrival, resume his duties as Post Surgeon at at post. S. O. 82, C. S. Dept. of the Gulf.
- SHUFELDT, R. W., Ass't Surgeon. To proceed at ce to Fort D. A. Russell, Wy. T., for duty with unpanies of 5th Cavy. detailed for field service near ntonment Reno, Wy. T. S. O. 65, Dept. of the atte, May 22, 1877.

Medical Items and News.

CONTAGIOUS DISEASES.—Comparative statement of cases of Contagious Disease reported to the Sanitary Bureau, Health Department, for the two weeks ending June 2, 1877.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-Spinal Meningitis.	Measles.	Diphtheria.	Small-pox.
May 26.....	0	5	89	3	59	40	3
June 2.....	1	9	101	2	47	47	3

ANTIQUEITY OF METATARSAL AMPUTATION.—Prof. O. Hubbard, referring to his article on the above subject in a recent number of the RECORD (Vol. XII., p. 81), writes: "In the third line, '1809' should read '17', and in the seventh line, page 315, 'proposed in 1809' should read, 'proposed in 1720.'"

LECTURES ON INSANITY.—During the present month Prof. A. E. Macdonald, M.D., Medical Superintendent of the New York City Asylum for Insane, Ward's Island, will give clinical lectures on Insanity in that institution on the afternoon of Thursday. The profession are invited to attend.

SIMULTANEOUS LIGATURE OF CAROTID AND SUBCLAVIAN OF RIGHT SIDE.—Prof. J. L. Little, M.D., of this city, successfully performed the above operation at St. Luke's Hospital, May 4, for aneurism of first part of the subclavian. The patient was a male, aged 45. The arteries were tied with the cat-gut ligature. The wounds have now healed, and the patient is doing well.

AN IRISHMAN'S IDEA OF A POST-MORTEM.—During the performance of an autopsy by us, an Irishman who happened to witness the removal of the heart and lungs from the body, exclaimed to a bystander, "Bedad, that's rough. I'd die first, before I'd let him do it to me."

THE MEDICAL SOCIETY OF THE STATE OF NEW YORK.—The seventy-first annual meeting will be held at Albany, in the Assembly Chamber, commencing on Tuesday, June 19, 1877, at eleven o'clock, and unless the Society should otherwise direct, the following will be the order of business:

TUESDAY, June 19.—*Morning Session.*—The Society will come to order at eleven o'clock, and the services will be opened with prayer. President's opening address.

*Announcement of Committees:* On Credentials; on Receptions and Arrangements; on Business; on Ethics; on Nominations.

Recess of fifteen minutes for organization of committees and the presentation of credentials of delegates to the Committee on Credentials, and for the registration of the names of permanent members on the roll. During the recess, strangers desiring to attend the meeting, should report themselves to the Committee on Receptions and Arrangements. All business communications, and all papers not entered upon this programme, should be handed to the Business Committee.

*Reorganization.*—Report of delegates in attendance, and the roll of present members by the Committee on Credentials; and on Receptions by the Committee on Receptions and Arrangements; introduction of delegates and visitors from other societies; communications from County Medical Societies.

*Reports of Officers and Committees of the Society:* Report of the Treasurer; Report of the Secretary as Librarian; Report of the Censors; Report of Committee on Publication; Report of Committee on Prize Essays; Report of Committee on By-Laws.

*Report of Delegates to other Societies:* Report of the Delegation to the International Medical Congress; Report of the Delegation to the American Medical Association; Report of Delegates to State Societies. Miscellaneous business, and adjourn at 1:30 P.M., to meet at 3 P.M.

*Afternoon Session.*—Reading of papers. Remarks and inquiries will be called for after the reading of each paper. Only a few minutes, however, can be allowed to each without special order of the Society. "The Use of Ergot," by Alex. H. Crosby, M.D., of Lowville, Lewis County; "Self-Suspension as a Means of Treatment in Lateral Curvature," by Lewis A. Sayre, M.D., of New York; "Four Cases of Sudden Death—Coroners' Inquests," by J. Kneeland, M.D., of South Onondaga; "Operation for Closure of Cleft of Hard Palate, with Report of Cases," by A. Van Derveer, M.D., of Albany; "An Obituary Notice of James Thorn, M.D."—read by title—by R. H. Ward, M.D., of Troy; "Sanitary Inspection in Schools," by William C. Wey, M.D., of Elmira; "Hydrophobia: Rabies Canina," by John W. Greene, M.D., of New York; "The Forceful and Rapid Dilata-

tion of the Cervical Canal, for the Cure of Anteflexion," by H. T. Hanks, M.D., of New York; "Puerperal Metastatic Irido-Chloroditis," by Thomas R. Pooley, M.D., of New York. Adjourn at 6 P.M. until 8 P.M.

*Evening Session.*—Papers not reached at one session will be called in the same order at the next session. "Ten Years Inside the Medical Society of the State of New York," by A. W. Tupper, M.D., of Washington County; "Climatic Influence in the Production of Nervous Disease," by A. McLean Hamilton, M.D., of New York; "Punctured Wound of Lung, Diaphragm and Liver, with Recovery," by S. L. Parmelee, M.D., of Watertown; "Report of Case of Fracture of the Base of the Skull, with Recovery," by Joshua B. Graves, M.D., of Corning. Adjourn at 10 P.M. to 9:30 A.M., June 20.

*WEDNESDAY, June 20.—Morning Session.*—Call to order at 9:30, and open with prayer. Minutes of all the sessions of the preceding day; reception of members and delegates from other societies; communications from County Medical Societies, including papers sent up for presentation, obituary notices, etc.; reports of officers and committees of the Society. These will be called in the same order as at the first morning session, and the reports not then presented or reached should be offered at this time. Miscellaneous business, and new business. "Discussion upon the Proper Time for holding the Annual Meetings of the Society;" "The Feasibility of Removing the Thyroid Gland in some Cases of Disease, with Illustrative Case," by Julius F. Miner, M.D., of Buffalo; "Pneumonic Fever: Grounds for Considering Acute Pneumonia an Essential Fever, and not Purely a Local Inflammation," by Austin Flint, M.D., of New York; "Two Cases of Convulsive Disorder without Convulsions," by Mary Putnam-Jacobi, M.D., of New York.

At 12 o'clock, or as near that time as the business under consideration will permit, the Report of the Special Committee—Dr. E. M. Moore, of Rochester, Chairman—upon the subject of Establishing a Committee to Determine the Qualifications of Students in Medical Colleges, who are about to enter the Profession; the services of such committee to be tendered to such colleges as may desire them. (See Transactions of 1876, p. 66.) This subject was made the special business for this hour of this session. Time unlimited. "Heredity as a Factor in Pauperism and Crime," by Edward H. Parker, M.D., of Poughkeepsie. Adjourn at 1 P.M. until 3 P.M.

*Afternoon Session.*—Reading of papers: "Nitrite of Amyl in Pertussis," by George Bayles, M.D., of New York; "Stone in the Bladder," by J. W. S. Gouley, M.D., of New York; "Pseudo-Membranous Laryngitis: Tracheotomy: Relapse and Recovery," by Norman L. Snow, M.D., of Albany; "Jaborandi," by Alexander Hutchins, M.D., of Brooklyn; "Tar Fumigations in Gangrenous Sores," by Lewis Post, M.D., of Lodi; "The Cold Bath in Scarletina (Clinical Notes)," by C. H. Giberson, M.D., of Brooklyn; "Vaginal Injections," by Frank P. Foster, M.D., of New York; "Some of the Morbid Conditions of the Prostate Gland," by Frederick Hyde, M.D., of Cortland; "Hydrochlorate of Ammonia—Ammonia Murias," by C. G. Pomeroy, M.D., of Newark, N. Y. Adjourn at 6 P.M. until 8 P.M.

*Evening Session.*—Report of the Committee on Hygiene—read in abstract, by A. N. Bell, M.D., Chairman, of Brooklyn; "Certain Points Relating to the Nature and Treatment of Lupus," by Henry G. Piffard, M.D., of New York; "Hereditary Transmission of Disease," by Ira F. Hart, M.D., of Elmira; "Fracture of the Base of the Skull," by P. R. H. Sawyer,

M.D., of Bedford; "Hæmophilia," by James C. Hutchison, M.D., of Troy; "Experience in Shoulder and Arm Presentations," by Israel Parsens, M.D., of Marcellus; "Cases of Wounds of the Synovial Membrane of the Knee-Joint Successfully Treated without Antiseptic Appliances," by George Burr, M.D., of Binghamton. Adjourn at 10 P.M. to 9:30 A.M. of Thursday, June 21.

*THURSDAY, June 21.—Morning Session.*—Call to order at 9:30 A.M., and open with prayer. Minutes of all the sessions of the preceding day; reception of members and delegates from other societies; communications from County Medical Societies; reports of Officers and Committees of the Society; Report of the Nominating Committee; election of officers, delegates etc., for the ensuing year; miscellaneous, unfinished and new business.

"Typhoid Infection of Drinking Water," by E. V. Stoddard, M.D., of Rochester; "Action of Mercury," by H. N. Eastman, M.D., of Owego; "Opium Inebriety and the Hypodermic Syringe," by S. F. McFarland, M.D., of Oxford. Adjournment.

**AMERICAN DERMATOLOGICAL SOCIETY.**—The first annual meeting of the American Dermatological Association will be held at Niagara Falls on the 4th day of September next. "The titles of all papers to be read at any annual session shall be forwarded to the secretary, Dr. L. Duncan Bulkley, N. Y., not later than one month before the first day of the session."

**PORTRAITS OF DISTINGUISHED MEDICAL MEN.**—F. Berendsohn, of this city, has published photographic copies (vignette size) of portraits of Sir Astle Cooper, and Drs. John Hunter and Richard Bright, of London. They are exceedingly well executed, beautifully mounted, and will make handsome office pictures.

**HOMŒOPATHIC COLLEGES.**—Some of the London medical journals admit advertisements of homœopathic schools.

**TURCO-RUSSIAN WAR.**—The Russian Minister of War has been compelled to decline the numerous offers of assistance on the part of French, German and Italian surgeons. Scurvy has made its appearance in the Turkish army.

**THE PLAGUE** has broken out in Resht.

**NO CORONERS IN FRANCE.**—There are no coroners in France. Persons who die suddenly are buried twenty-four hours after death on the mere certificate of a doctor. It is only when the death is sufficiently mysterious to excite suspicion that the *procureur* is sent for and orders a post-mortem examination. It can be easily seen that the cautious murderers have good chance to escape.

**NEW YORK HOSPITAL.**—All the improvements which experience in hospital construction could suggest, have been made in the New York Hospital building, West Fifteenth Street. Besides the several laboratories, wards there is a recreation room for convalescents, and a number of private apartments for those who means enable them to pay for such accommodations. As far as the hospital proper is concerned, nothing is left to be desired. With the out-door department the case is quite different.

**HOUSE OF RELIEF IN CHAMBERS STREET.**—The House of Relief, at 160 Chambers Street, reports 5,455 patients treated in the Dispensary, and 506 in the Wards, during 1876. There were 41 surgical operations, and ambulance made 978 calls, the average time occupied by each call being 30.7 m.

## AMERICAN MEDICAL ASSOCIATION.

THE recent meeting of the American Medical Association has been as successful as any which has been held during the past few years. The attendance was unusually large, and the interest manifested in the proceedings by the members and delegates was everything that could have been expected. A few questions engaged the attention of the Association, the discussion of which was a little heated, but the utmost good feeling prevailed.

Dr. Davis, one of the founders of the organization—always ready with a speech—gave the address of welcome. The address of the President, Dr. Bowditch, dealt chiefly with questions referring to the working machinery and efficiency of the Association. He touched on several abuses in the working of the organization which have done much to bring it into disgrace in the past. One of these is the present objectionable habit of printing everything that is presented at the meetings in the Transactions, whereby a bulky, diffuse, and nearly useless, but expensive volume is yearly turned out. Another source of weakness referred to is the rule allowing a representative to every ten members of every local society, so that the Association is each year practically made up largely of such men as only care to take a trip, or to spend their vacation in sight-seeing and with agreeable company. Of course this calls together many representative and very fine men, but Dr. Bowditch would have the representation more restricted. He advocated some closer association or union with the profession in Canada. The entertainment of the Association with intoxicating beverages was forcibly, if not deservedly, rebuked. The library and museum of the Surgeon-General's office, as usual, commended to the aid and support of the profession and Congress. The reference to the necessity of change in the revision of the U. S. Pharmacopœia, although perfectly non-committal, answered the purpose, however, of bringing the subject in a formal way before the Association.

Dr. Squibb made his communication on this question in two parts and under serious disadvantages on account of the pressure of business. His paper was a strong argument in favor of an improved Pharmacopœia, and while it found a large majority of the members opposed to his scheme it left the Association undoubtedly in favor of something better in the way of a national standard. It certainly opened the eyes of the assembly to some of the shortcomings and exclusiveness of the present instrumentality for the decennial revision. His argument went far to convince the members of the groundlessness of the notion that it is impossible for the profession of the United States to establish and have a Pharmacopœia such as it desires.

A memorial was presented from the New Jersey State Medical Society advocating some scheme for improvement akin to that of Dr. Squibb. Dr. H. C. Wood—as might have been expected—made a short speech, strong and forcible, against the plan proposed by Dr. Squibb, when Dr. Davis moved, in the interest of harmony in the Association, that the whole subject regarding the Pharmacopœia be indefinitely postponed. This settled the question in a way entirely satisfactory to Dr. Squibb, who justly complained that, contrary to any intention or desire of his own, he had been drawn into the discussion more in a personal than in a general way, more as an exponent of a principle than the principle itself.

This session of the Association, in its scientific aspect, was more of a success than many of its predecessors. The Sections have all been in thorough organization, and in each important papers were read, which in nearly every case led to animated discussion.

It is in the Sections that the better part of the scientific work must always be done. The chairman of each Section is booked each year for an address in the general session. Each year it is demonstrated—this year with the rest—that it is impossible to make these scientific papers; they are addresses, and are less valuable, scientifically, than the papers read in the Sections.

One of the most scholarly and eloquent addresses of this session was that of Dr. Ezra M. Hunt, of New Jersey, on "State Medicine and Public Hygiene." The meeting was well entertained, too, by the addresses of Dr. Robinson, of St. Louis, on Practical Medicine, and that of Dr. White, of Buffalo, on Obstetrics.

Altogether, then, the Association has been a fine success without the occurrence of any event of great mark.

## SANITARY INSPECTION OF SCHOOLS.

THE resolution recently passed by the Board of Education, to refer the sanitary inspection of the schools to the Board of Health, if it means anything, anticipates some very urgent and necessary reforms. It is well known that the school-bill to provide for such inspection failed to pass at the recent session of the

State Legislature, and that such a result was brought about in no small degree by the direct interference of the School Board. Why the latter should now go back on its previous record is somewhat difficult to understand, unless we look upon the action as a mere stroke of policy to blind the public. The inspection will doubtless be made, but what will be gained by it? Nothing more than the old story that the schools are overcrowded, that ventilation and sewerage is defective, that contagious diseases are spread among the children, and that all these things should be remedied. If any new facts shall be obtained they can hardly be in favor of the previous policy of the School Board, which has heretofore been criminally neglectful. But the necessity for such inspections has passed. The unsanitary condition of the schools is well known; what is wanted now is active, intelligent, and radical reform. What hope is there for this when the School Board has the power to do as it pleases with the reports and recommendations which may be sent to it? If the application of the necessary remedies is left to the Health Board there is a reasonable chance that something may be done, but if the School Board itself is to be depended upon to take any action, and if we are to judge the future by the past, we are merely risking hope upon a broken reed. But let us be thankful even for a show of good intentions, and patiently wait the fulfilment of their implied promise.

#### THE HUNTER'S POINT NUISANCE.

As might have been anticipated, the intolerably offensive smells which are wafted by the east wind over this city from the factories at Hunter's Point, L. I., have aroused considerable public indignation. Probably in no city of equal size has a greater cause for complaint existed with as little hope for a remedy. Our Health Board is powerless to do anything, as the provisions of its charter place the obnoxious factories beyond its jurisdiction. Last winter an attempt was made to pass a law which should give the health boards of large cities the power to control suburban nuisances, but, like all measures which have merely a sanitary bearing, it was easily defeated by the parties interested in perpetuating the nuisance. Far from gaining any relief, the sickening odors are worse than ever, as the means for their manufacture have multiplied in the shape of extensions to the original works. The very intolerableness of the nuisance gives now the best hope for some prompt remedy. It has become now a matter which affects the comfort if not health of the larger portion of the inhabitants of Manhattan Island, and there does not seem to be much of an inclination to submit to the imposition for the sake of mere policy. How this remedy is to be applied until the meeting of the next Legislature does not now appear.

DR. THOMAS B. STIRLING, a prominent practitioner of this city, died suddenly June 10th.

## Progress of Medical Science.

THE STING OF THE SCORPION AND ITS TREATMENT.—Dr. Julius A. Skelton, editor of *The Observator Medico*, of Mexico City, has furnished us with an interesting article by Dr. Puerte, on the sting of the scorpion, and its effects, which have been seldom described in medical works. The insects he describes are found in the districts of Matamoras, Izucar, Chautla de la Sal, and the municipalities of Chietla, situated to the south of the city of Puebla. The largest of the scorpions are found in the first-named locality, and they are generally four or five centimetres in length and of an orange-red color, though sometimes brown. They are provided with eight feet, two horns, and a tail, which has four or five rings, the last being the largest and carrying the poison sac. Each of the horns has two articulations, the foremost carrying the poison. The first pair of legs have appendices in the form of pincers.

These insects live in the sugar fields and gardens, where they may be found under stones, or in the foliage of the plants. In towns they find a resting place in the cracks of the timbers, under the furniture, or in the rubbish of uncleanly houses. When an individual has been stung the symptoms may be grouped in three distinct periods. In the first there is heat and pain at the injured spot, general sleepiness, frequent sneezing, restlessness, and slight strabismus. In the second stage saliva is abundantly secreted, there is meteorism, dilatation of the pupils, and a pulse varying between 100 and 120. In the third stage there is trismus, or tetanus. The first period occurs soon after the sting, and lasts from a quarter of an hour to an hour; the second, a little more than fifteen minutes; and the third may be prolonged to three days. The domestic remedies are various. Sometimes ammonia and garlic are applied externally, and watermelon internally. The gum of the white cuaxiote has also given satisfactory results. Dr. Puerte's method of treatment in the first stage consists in administering diaphoretics, together with alcohol of ten per cent. solution in teaspoonful doses every half hour.

If, however, the second stage supervenes, he continues the alcohol and gives a vapor bath, and, finally, a weak infusion of the flowers of the *Laurus Cerasus*. In the third period he always makes use of the inhalations of chloroform, and records a successful cure in each instance. Among the native Indians cases of this kind are very frequent, and many of the children die. In all children under four years of age the sting is usually fatal; between six and ten severe but not mortal while adults never die. Many persons claim to have been stung without experiencing any symptoms. This in Dr. Puerte's opinion, is because the clothing has absorbed the virus, a fact he seems to have proved experimentally. When the naked skin receives the virus, symptoms of poisoning are sure to follow.

CLIMATE AND PHTHISIS.—A change of climate is so often resorted to by persons suffering from phthisis, it would be interesting to note that the investigation of specialists have shown that the occurrence of phthisis decreases or ceases altogether above a certain elevation. Dr. Gleitsmann, of Baltimore, has collected from various sources tables showing the relative mortality according to months, seasons, sex, age, locality, etc. The percentage of deaths in the spring months is shown to be larger than in the other season and this is accounted for by the humidity of the atmosphere and the frequent thaws and rains.

## American Medical Association.

### TWENTY-EIGHTH ANNUAL MEETING,

HELD IN THE CITY OF CHICAGO, JUNE 5, 6, 7 AND 8, 1877.

TUESDAY, JUNE 5.—FIRST DAY.

THE Association met in Farwell Hall, and was called to order at 11 A.M., June 5, 1877, by Dr. J. Marion Sims, the retiring President, who in fitting words thanked the Association for the honors it had conferred upon him, paid a flattering compliment to the founder of the Association, Dr. N. S. Davis, of Chicago, and with a glowing reference to the labors of Dr. H. I. Bowditch, of Boston, introduced him as the incoming President.

DR. BOWDITCH congratulated the Association most cordially upon its meeting in this the queen city of the West under such propitious circumstances, and expressed the hope that all would retire from the meeting feeling that they possessed good-will toward all men, and that they had learned something which might be utilized for the benefit of suffering humanity, and which could be carried pleasantly with them until transferred from this sphere of earthly activity.

Prayer was offered by Rev. Wm. L. Harris, D.D., LL.D.

DR. N. S. DAVIS, chairman of the Committee of Arrangements, delivered the address of welcome, which was full of pleasing references to the growing city of the West, to her aqueduct, her groves, her institutions of learning, and her commercial advantages. A touching reference was made to the preliminary meeting held thirty-one years ago in the city of New York for the organization of the American Medical Association. In that meeting there were seventy six voters. Of that number only one could be seen in the present meeting, and that member was Dr. W. T. Atlee, of Philadelphia. Nearly all the original number had passed to their final reward. Of the twenty-eight presidents sixteen had gone to their everlasting reward. Reference was made to the death of Dr. Henry F. Askew, of Delaware, an ex-president of the Association. Dr. Davis closed his address by declaring the delegates thrice welcome to the hospitality of the city.

DR. NORMAN BRIDGE, chairman of the Committee of Registration, read the list of delegates whose credentials had been approved, and whose names had been duly registered.

The following gentlemen were elected members by invitation: D. F. Boughton, of Mendota, Wis.; W. H. Bunker, of Cincinnati; J. A. Reed, Dixmont, Pa.; D. Leavitt, and Eichberger, of Terre Haute.

The following gentlemen were elected permanent members: Drs. J. K. Bartlett and E. W. Cross, of Minnesota; Drs. D. A. K. Steele, S. A. McWilliams, John E. Owens, Charles T. Parks, E. O. F. Roler, Charles L. Rutter, D. F. Nelson, J. S. Knox, W. E. Juins, W. S. Nevins, M. P. Hatfield, Thomas Bevan, J. W. Sawyer, and L. H. Montgomery, all of Chicago, and S. M. Hamilton, of Monmouth, Ill.

The President invited the retiring President, and also the delegates from the Canadas, to take a seat upon the platform.

#### PRESIDENT'S ADDRESS.

Dr. Bowditch then delivered the President's annual

address, in which he first referred to the past of the Association, contrasting its first meeting—when it was a body of heterogeneous natures, with nothing especially to unite them—with the large, harmonious meetings it now holds every year. Before its inauguration the profession was disintegrated, and members knew little of one another, except those in their own home circle, while now the Association embraced men from the most distant parts of the country, who were brought face to face at these annual gatherings. Dr. Bowditch looked back on the enthusiasm of the first meeting, and contrasted its spirit with the point-of-order discussions at the business meetings and the wine-drinking at the social gatherings which had been rather too prominent features of some of the Association's meetings. For this and other reasons there had been opposition to the Association. One particular reason was, the general expectations had been raised to too high a pitch for the Association to realize them. Besides, a society made up of so many different elements, coming together only once a year, could not carry on any fine scientific work. The Association should meet more frequently. In fact, what was needed was small and frequent reunions.

The Transactions of the Association, moreover, were too bulky, so that they depressed rather than excited the enthusiasm of the readers. It must be confessed that this was indeed one great reason why the reputation of the Association had been lowered. He made these observations in no merely captious spirit, but because he believed there was no better way to make improvements than by looking fairly at figures. These objections, he believed, as well as others, could be removed, and new vigor be put into the Association.

In the first place, there was chance for improvement in the Sections. There was not enough criticism of the papers read, nor was it exactly the right kind. He thought the Association should adopt the plan in operation at the Smithsonian Institute—not to publish anything until after it had been submitted to and approved by experts, whose decisions were final. The Association should further declare as its rule for the guidance of such experts, that no paper should be deemed worthy of publication which did not give something new to medical science, or which did not present such an analysis or such a new or lucid arrangement of facts already wholly or in part known as to greatly aid the profession. Dr. Bowditch hoped these recommendations would be referred to the Judicial Council, to report at this meeting. To this Council he would also have referred the question of the propriety of having a standing committee of one to procure scientific papers for the annual meeting from the best men in the country.

This Association, to its praise be it said, had also extended an invitation to women to meet with it. Dr. Bowditch favored conducting the public entertainments upon temperance principles, and thought the Association should take the highest ground against the use of intoxicating drinks among its members. Such action would have the most important effect on the noble cause of temperance throughout the land.

Dr. Bowditch also thought that every member of a State Society should be a permanent member of this Association. Dr. Bowditch was also in favor of reduced representation. He would have a Society send one delegate for every twenty or thirty members, instead of one for every ten, and he believed that with this change the honor of being a delegate would be more sought after, and that it would devolve upon the very best men in the profession, which was not always the case at present.

The President also considered at some length the proposition for the union of the American Medical Association and the Canada Medical Association, and stated the arguments for and against the proposed union. The principal objections to it were the present large dimensions of this Association; the fact that, owing to the use of two languages in Canada, joint meetings would be objectionable; the difficulty of arranging the expenses of a united body; and lastly, the confusion which would probably result from each place of meeting being so far distant from the preceding. On the other hand, the physicians in the United States should associate themselves with a body of physicians all of whom had been educated under English influence, and many of whom had pursued their studies in England and obtained their diplomas there. Again, he was inclined to favor this union from the stand-point of civilization itself.

Dr. Bowditch suggested that the matter be referred to the Judicial Council, to report during the meeting on the feasibility of the union.

To the subject of the revision of the American Pharmacopœia, and the proposed rejection of the one in use and the substitution therefor of an entirely new, more modern, and more complete work on that subject, Dr. Bowditch referred at considerable length. He was not prepared to recommend any of the plans yet put forward, because more light was needed on this very important subject. He thought it wise to refer the whole subject to the Judicial Council.

Dr. Bowditch spoke of the importance of State Boards of Health, and impressed upon his hearers the necessity of conversing with, or writing to, their representatives in Congress in reference to the museum and library of the Surgeon-General of the army.

In closing, Dr. Bowditch said that the Association, for the sake of good learning in America, should cordially welcome to its meetings every prominent physician in the country, and if those who did attend the meetings would determine that nothing but what was excellent should be published in its works, then they would be doing a really noble work, and the Association would eventually claim the highest respect of the whole profession. It was growing stronger every year. It had enjoyed a perpetual youth, a stalwart manhood, and, he sincerely trusted, it would live to a genial old age.

On motion made by Dr. BRODIE, of Detroit, the thanks of the Association were returned to its President for his interesting address. The address was referred to the Committee on Publication.

Dr. BRODIE further moved that a committee of seven be appointed to report upon the recommendations embraced in the President's address.

The first Vice-President, Dr. N. J. PITTMAN, of North Carolina, announced the committee, as follows: Dr. W. B. Brodie, of Detroit; Dr. S. D. Gross, of Philadelphia; Dr. E. Grissom, of North Carolina; Dr. J. R. Smith, of U. S. A.; Dr. J. R. Bartlett, of Minnesota; Dr. J. P. White, of Buffalo; Dr. J. M. Toner, of Washington.

A number of papers were then read by title and referred to their appropriate sections; after which the Association adjourned to meet at 9.30 A.M. on Wednesday, June 6, 1877.

#### WEDNESDAY, JUNE 6.—SECOND DAY.

The Association was called to order at 9.30 A.M. by the President. The minutes of the previous meeting were read and approved. A recess of ten minutes was taken to allow the delegations opportunity to

select their representatives for the Nominating Committee, and report such selections to the Secretary.

The following volunteer papers were referred to their appropriate Sections: *On Plastic Splints*, by Dr. H. O. Marcy, of Massachusetts; *On Epithelioma*, by Dr. S. P. Breed, of *A New Speculum*, by Dr. E. A. Hildreth, of West Virginia; *On Conservative Surgery*, by Dr. I. N. Quimby, of New Jersey; *A New Instrument*, exhibited by Dr. H. I. Bowditch, of Boston.

#### PERMANENT MEMBERS.

Dr. DAVIS submitted the following names for election as permanent members: Drs. F. C. Schaefer, Chicago; W. H. Fitch, Rockford, Ill.; H. Chapman, Hudson, Mich.; G. E. Willard, Chicago; C. C. Hunt, Dixon, Ill.; J. J. Stone, G. Benedict, and J. H. Stewart, of Minnesota; J. N. O'Brien, Plymouth, Wis.; R. Dexter, and J. Vider.

#### REPORT ON THE PRESIDENT'S ADDRESS.

Dr. BRODIE, of Michigan, chairman of the special committee appointed to consider the recommendations embodied in the President's annual address, submitted the following report:

"Your special committee, to whom was referred the recommendations in the President's annual address, respectfully report that they have had the same under consideration, and recommend as follows:

"1. The Smithsonian plan: It is believed that if the officers of the Sections should perform their duties promptly under the existing regulations, there would be no necessity for further examination.

"2. In the matter of a standing committee to procure papers on scientific subjects, it is or should be part of the duty of the chairmen of the Sections to obtain suitable matter for their respective Sections, at as early a time after their appointment as possible; and it is believed this would effect what the President proposes.

"3. On permanent members and representation, we do not think it best at the present time to make or suggest any change in the present plan of organization.

"4. On the union of this Association with the Canada Medical Association, we consider the same impracticable, and are of opinion that the present system of intercourse between the societies by delegates serves to meet the requirement.

"5. On the question of the Pharmacopœia, we deem it inexpedient at the present time to take any action in the premises."

On motion made by Dr. BOWDITCH, the report was laid upon the table.

#### REVISION OF THE U. S. PHARMACOPŒIA.

The hour of ten having arrived, Dr. E. R. SQUIBB of New York, spoke on the revision of the United States Pharmacopœia. He stated that he was read to report on this important matter, but saw from the programme that only one hour had been allowed for it. He would be unable to do more than to make brief allusion to the matter in that time, and was willing to dispose of it in any such cursory manner. It was deserving of a long and deliberate consideration. Yet he was willing to conform with the wish of the Association and do as directed.

Dr. DAVIS, on behalf of the Committee on Arrangements, said that though this subject had been assigned to this hour, it might be laid on the table, at the close of the hour, for further consideration.

It was decided, on motion of Dr. GALLAHER, hear Dr. Squibb to the end of the hour.

The report, as read by Dr. Squibb, involved full résumé of the arguments *pro* and *con* on the

revision of the Pharmacopœia. It involved copious quotations from Dr. Wood's well-known pamphlet on the subject. It denied the allegations of Dr. Wood that it was the intention, by the proposed innovations, to abolish the old Pharmacopœia, but asserted that the design was to improve the present plan by introducing new and important revisions. Nor was it designed to interfere with the "Dispensatory," but merely to have a Pharmacopœia without a Dispensatory. It was intended by the new revision simply to undertake a work which the old Pharmacopœia did not do. He explained that it was intended by the revision to make the Pharmacopœia explain its own assertions, or definitions, without the aid of a Dispensatory. He referred to many mistakes in the Pharmacopœia of 1877, showing little improvement since 1873, and which should be remedied. In refutation of the argument that the whole profession, by the proposed plan, would be under the control of one man, he averred that it should be remembered that that man would be the President of the American Medical Association; and that no more impropriety obtained in that than in the representation of an entire Government by one Minister, as often occurred in national matters.

The time having arrived for another order of business, the subject was referred to the Committee on Arrangements to appoint an hour for its further consideration.

The next order of business was an

#### ADDRESS BY THE CHAIRMAN OF THE SECTION IN PRACTICAL MEDICINE, ETC.,

which was delivered by Dr. P. G. ROBINSON, of Missouri. The address consisted of a review of the progress made in medicine during the past year. It had been fully shown that accumulations of sewerage and the like became centres of contagion. Especial attention was directed to the etiology of specific fevers, notably the typhoid, and reference was made to the outbreak which occurred in Lancashire, England, in consequence of using milk supplied from one dairy. The attention of the Association was called to an article in the July number of the *American Journal of Medical Sciences*, where the cure of a case of *abies canina* by the use of strychnine was reported by Dr. Watson, of Jersey City. In his case there was no aversion to water shown, and for that and some other reasons a number of physicians held that it was a true case of hydrophobia. The great question to be settled was that of diagnosis.

Dr. Robinson then passed to a consideration of the use of salicine and salicylic acid in the treatment of acute inflammatory rheumatism. These had been used with great advantage in various hospitals, both abroad and at home, and there was no doubt that a means of alleviating this terrible disease had been found.

Reference was made to the value of counting the blood-corpuscles in certain affections, and quotations made from several French authors.

In physiology reference was made to the labors of Briër, Fritz and Hitzig, Dalton, Mitchell, Hughlings Jackson, and others, regarding the localization of function in the brain, the function of the corpora quadrigemina, the duality of the vaso-motor system.

During the past year several drugs had been brought into use, and special mention was made of the use of gelseminum in the treatment of facial neuralgia, salicylic acid as an internal and external remedy, erythroxylon coca, and several other articles. The address was well received, and referred to the Committee on Publication.

#### ADDRESS OF THE CHAIRMAN OF THE SECTION ON OBSTETRICS.

DR. JAS. P. WHITE, of Buffalo, N. Y., delivered the address, and began by saying that the most notable event of the year was the formation of the American Gynecological Society, and its transactions and publications were of great interest to the medical profession. Dr. White then called attention to a number of books and pamphlets in relation to this particular branch of medical study which were published last year.

Special and favorable mention was made of the writings of the late Dr. John S. Parry, and his book was reviewed to considerable length. The papers of Dr. Isaac E. Taylor, read before the New York Academy of Medicine, received special notice, and he was inclined to differ with Dr. Taylor as to the value of Cesarean section when compared with craniotomy. The theory of Dr. Maxson, of Syracuse, N. Y., regarding the value of the knee-and-elbow position in the management of cases of malposition of the fœtus, received favorable mention. Pneumatic pressure, by Dr. Campbell, of Georgia, was noticed and believed to possess some value. Dr. White was pleased to notice the growing sentiment in favor of the use of the obstetrical forceps, and exhibited a pair made in accordance with his own views regarding the construction of the instrument. The management of placenta previa was under consideration when the hour expired.

#### COMMITTEE ON NOMINATIONS.

The Committee on Nominations was announced as follows: Dr. J. M. Keller, Arkansas; Dr. L. M. Lovelace, California; Dr. C. R. Bissell, Colorado; Dr. H. M. Knight, Connecticut; Dr. W. Marshall, Delaware; Dr. W. H. Ross, District of Columbia; Dr. R. Battey, Georgia; Dr. C. H. Rawson, Iowa; Dr. F. D. Fitell, Illinois; Dr. G. Sutton, Indiana; Dr. W. L. Schenek, Kansas; Dr. D. W. Yandell, Kentucky; Dr. J. C. Egan, Louisiana; Dr. W. B. Cobb, Maine; Dr. H. O. Marey, Massachusetts; Dr. C. H. Ohr, Maryland; Dr. L. Connor, Michigan; Dr. C. P. Adams, Minnesota; Dr. T. B. Lester, Missouri; Dr. W. M. Compton, Mississippi; Dr. S. G. Dearborn, New Hampshire; Dr. S. Lilly, New Jersey; Dr. J. P. Gray, New York; Dr. E. Grissoni, North Carolina; Dr. W. W. Jones, Ohio; Dr. S. D. Gross, Pennsylvania; Dr. W. H. Palmer, Rhode Island; Dr. W. H. Goddings, South Carolina; Dr. D. J. Roberts, Tennessee; Dr. A. E. Carothers, Texas; Dr. William R. Hutchinson, Vermont; Dr. F. D. Cunningham, Virginia; Dr. J. C. Hupp, West Virginia; Dr. J. T. Reeve, Wisconsin; Dr. J. R. Smith, United States Army.

Dr. Nichols, of the District of Columbia, President of the Association of Superintendents of Insane Asylums of the United States, was then introduced by Dr. N. S. Davis, and the Association adjourned to meet at 9:30 A.M., June 7, 1877.

#### THURSDAY, JUNE 7, 1877.—THIRD DAY.

The Association was called to order at 9:30 A.M. by the President.

After the transaction of the usual introductory business,

DR. N. S. DAVIS, Chairman of the Committee of Arrangements, recommended the following gentlemen as

#### MEMBERS BY INVITATION:

Dr. H. P. Godfrey, of Berlin, Wis.; Dr. J. R. Moffatt, Prairie du Chien; Dr. R. G. Floyd, Whitehall, Wis.; Dr. J. P. Everett, Dixon, Ill.; Dr. Tru-

man Miller, Chicago; Dr. Thomas R. Douglas, Pennsylvania; Dr. C. N. Fitch, Chicago.

The following gentlemen were recommended and elected

PERMANENT MEMBERS:

Samuel Tibbits, M.D., Kirkwood, Ill.; G. M. Chamberlain, M.D., Chicago; C. G. Simmons, M.D., Chicago; Charles W. Chaffee, M.D., Chicago; William M. Kaull, M.D., Princeton, Ill.; James H. Wallace, M.D., Monmouth, Ill.; John A. Meek, M.D., Jonesboro, Ind.; Josiah Rogers, M.D., Ripon, Wis.

Dr. Norman Bridge, Chairman of the Registration Committee, read the list of delegates enrolled since the first day. The whole number in attendance was 700.

Report from Judicial Council was made and adopted.

A communication from Dr. H. I. Bowditch upon the relative value of incision and aspiration in the treatment of empyema and hydrothorax was referred to the Surgical Section.

TREASURER'S REPORT—THE EXPENSE OF THE PRIZE ESSAY.

The Treasurer had the honor to report that, under positive instructions of the Association, the Prize Essay had been published at a cost of some \$6,000. This unusual outlay, in addition to the unusual volume of the Transactions, left the treasury in an exhausted condition, as it had practically given to each member \$9 in value for \$5 received.

In this, his last report, after twenty-two years of service, it remained for the Treasurer to thank the Association for its long-continued confidence, and to regret that in leaving the treasury solvent, he could not leave a more abundant surplus.

The amount in the treasury was \$172.72.

REPORT OF THE COMMITTEE ON PUBLICATION—REASONS FOR DELAY IN APPEARANCE OF VOLUME.

The committee was constrained to acknowledge that the late date at which the volume for 1876 (vol. xxvii. of the series) was issued needed explanation. The delay of a few months subsequent to the annual meeting was, of course, due to the fact to which attention has many times been called, that the edition which it was proper to print could not be arrived at except by means of answers to circulars sent to the members. It was unpleasant to find fault at all, but to be compelled to complain of annually recurring neglect, if not downright inefficiency, was an exceedingly ungracious task. The Committee on Publication was profoundly convinced that the proceedings of a medical body like the American Medical Association could be adequately reported by men of medical education alone. No skill or training could compensate for the lack of this qualification. And yet for several years past the committee had been annually delayed by a mass of copy prepared by professional reporters, of which a large portion had been unfit to be put into the hands of the printer. Had it not been for the kind co-operation of several members who had attended the last session of the Association and who had participated in the discussions, the Committee of Publication would have been hopelessly embarrassed, and would have been forced to eliminate paragraph after paragraph from the minutes. To these causes the delay in the issue of the volume has been principally due; and in view of them the committee thought it could consistently claim the indulgence of the Association.

The Prize Essay was put through the press as

promptly as the very elaborate character of the work permitted.

Of volume xxvii. 1,250 copies were printed; 1,207 copies have been distributed to members, and 43 copies are on hand.

Of the Prize Essay, 1,250 copies were printed; 1,067 copies have been distributed, leaving 183 copies on hand.

PRIZE ESSAYS.

DR. DAVIS, from the Committee on Prize Essays, reported that only one essay had been submitted in time to receive examination, and that the committee did not regard as entitled to receive the prize offered by the Association.

Another essay had been received, but it came too late to have an examination, and it was recommended that the author have the privilege of withdrawing his essay. It was recommended that it be presented for competition next year, sufficiently early to secure examination. The report was adopted.

LIBRARIAN'S REPORT.

DR. ATKINSON, as Secretary, read the report for the year of William Lee, Librarian. It showed that 187 distinct titles had been added to the library the past year, making the number now embodied in the library 817 distinct titles, and 2,034 volumes. The report showed that the library, on general principles, was in good condition.

ADDRESS OF THE CHAIRMAN OF THE SECTION ON STATE MEDICINE AND PUBLIC HYGIENE.

DR. EZRA M. HUNT, of New Jersey, read an elaborate and able paper on the subject embraced within his jurisdiction. He reviewed all that many men had done to diffuse health and life-saving practices throughout the world the past year. He spoke of what was needful for more salutary and sanitary medical treatment of the public. He dwelt upon the ways by which this important subject should be brought to the notice of the profession, as one of the profoundest importance. He urged that the Association, as representing the profession largely, should urge the more thorough teaching of this sanitary law in all the medical schools. He thought the profession had reason to congratulate itself that this country was fast perfecting its system of public hygiene. The address was properly referred.

THE U. S. PHARMACOPŒIA.

DR. E. R. SQUIBB resumed his report upon the above subject at the point where it was discontinued in yesterday's proceedings. He combated with logical force the arguments against the proposed revision, and with equally forcible diction spoke of the advantages of the new scheme. He closed his remarks by saying that there were three courses for the Association to pursue: First, to lay the whole matter on the table, leaving it exactly as it was, on the ground that the Association was not necessarily involved in revising the Pharmacopœia at all; second, the Association might make Pharmacopœia, such as it saw fit, allowing it to take its chances with others. He thought this latter plan would not eventuate a Pharmacopœia which would be accepted by the army and navy. The third plan was for the Association to appoint a committee to consider the matter in detail and report in 1878, on which occasion all the State societies should send their delegates, thoroughly instructed as to their ideas on the subject.

Dr. Squibb moved that the whole matter be referred

upon the table, but objection being made by Dr. Davis that such a proceeding would deprive the opponents of the revision of the Pharmacopœia from expressing their sentiments, Dr. Squibb withdrew his motion and the matter was thrown open for discussion.

Dr. SQUIBB wished to state that he did not appear as the advocate of either one or the other plan, but was willing to abide by the decision of the Association. He simply preferred that the first course should be followed, as by laying the matter on the table he would be relieved from further responsibility on this mooted question.

Dr. H. C. WOOD, of Philadelphia, who had issued a pamphlet in opposition to the scheme, from which Dr. Squibb had read, spoke at some length. He maintained that no action was necessary to be taken by this Association, and that the only thing necessary to make the Pharmacopœia better was for the physicians of this country to awaken to a realization of their duty to make it so, of attending the conventions and doing their duty toward improving the book.

He deeply deplored the fact that this matter was awakening and protracting dissension among the elements of this Association.

Dr. BRODIE, of Detroit, submitted the following resolution:

*Resolved*, That a committee of five be appointed by the President, to whom shall be referred the paper of Dr. Squibb and other papers on the subject of the Pharmacopœia, with full authority to examine into the whole question as to the propriety of this Association being a factor in whole or in part in this publication, and report at the next annual meeting."

Pending the adoption of this resolution, Dr. N. S. DAVIS took the floor, and indorsed with earnestness the remarks of Dr. Wood. He regretted that this old matter should drag along through the annual meetings, occasioning discord and disputation. He thought that the only duty this Association had to perform in instituting a new Pharmacopœia was to see to it that such improvements were made as were necessary.

Dr. BRODIE withdrew his resolution, and Dr. DAVIS moved that the subject be postponed indefinitely. Carried.

#### REPORT OF THE NOMINATING COMMITTEE.

Dr. S. D. GROSS, Chairman of the Committee, made the following report, which was accepted and adopted by the Association.

For President, Dr. T. G. Richardson, of Louisiana. Vice-Presidents: Dr. J. P. White, of New York; Dr. M. Gunn, of Illinois; Dr. G. W. Russell, of Connecticut; Dr. A. Dunlap, of Ohio. For Chairman of the Section of Medicine, Materia Medica, and Physiology, Dr. A. L. Loomis, of New York; for Secretary, Dr. J. H. Etheridge, of Illinois. Chairman of Section of Obstetrics and Diseases of Women and Children, Dr. E. W. Jencks, of Michigan; for Secretary, Dr. H. A. Marey, of Massachusetts. Chairman of Section of Surgery and Anatomy, Dr. H. H. Smith, of Pennsylvania; for Secretary, Dr. E. Z. Early, of Arkansas. Chairman of Section on Medical Jurisprudence, Chemistry, and Psychology, Dr. W. Kempster, of Wisconsin; for Secretary, Dr. E. A. Hildreth, of West Virginia. Chairman of Section of State Medical and Public Hygiene, Dr. J. L. Cabell, of Virginia; for Secretary, Dr. E. J. Marsh, of New York.

The same committee also recommended that the next annual meeting be held at Buffalo, N. Y., commencing on the first Tuesday in June, 1878.

The Association then adjourned, to meet at 9.30 A.M. Friday, June 8, 1877.

FRIDAY, JUNE 8, 1877.—FOURTH DAY.

The Association was called to order at 9.30 A.M. The President, Dr. H. I. Bowditch, in the chair. The minutes of the last meeting were read and approved.

Dr. S. LILLY presented a memorial from the New Jersey State Medical Society with regard to the U. S. Pharmacopœia. It was entered upon the minutes.

#### MEMBERS BY INVITATION AND PERMANENT MEMBERS.

Dr. C. M. Fitch, of Chicago, was elected a member of the Association by invitation; and Drs. L. H. Chew, of Naperville, Ill., and S. O. Ritchie, of Chicago, were elected permanent members.

A list of charges were presented against the Michigan State Medical Society, the import of which was that it had aided and abetted the Michigan University in graduating scholars in an irregular and exclusive medical course of study. Referred to Judicial Council.

#### STATE BOARDS OF HEALTH.

Dr. ATKINSON submitted the report of the Permanent Secretary, made in conformity with an order issued in 1875, on State Boards of Health, showing that circulars had been forwarded to the Executive of each State in which a health board had not already been organized, urging the need and utility of such boards, and soliciting that the subject be brought before the Legislature; that State Boards now existed in Alabama, California, Colorado, Georgia, Illinois, Louisiana, Maryland, Massachusetts, Minnesota, Mississippi, North Carolina, New Jersey, Tennessee, Virginia and Wisconsin, and that resolutions had been introduced into other State Legislatures to effect the establishment of boards; and suggesting that the committee be continued.

This report was ordered to be entered upon the minutes.

#### MEDICAL OBSERVATION AND RECORD.

The Secretary also read a report made by Dr. Edward Seguin, of New York, and Dr. J. J. Woodward, U. S. A., on the subject of Uniformity in Medical Observation and Record, showing the paramount need that existed for such uniformity, and recommending that the Association send delegates to the International Convention to be held in Geneva, in 1877-78, who should advocate the devisement and institution of a plan to secure more systematic operation in that matter. The report was adopted.

The Secretary moved that Thomas M. Drysdale, of Philadelphia, be appointed a delegate to foreign Medical Associations; and that Clifton E. Wing, of Boston, be appointed delegate to the Canada Medical Association. These gentlemen were so appointed.

The minutes of the Judicial Council were entered without reading.

#### REPORTS FROM SECTIONS.

Reports from the Chairmen of the Sections on Obstetrics, State Medicine and Public Hygiene, Surgery and Anatomy, Medical Jurisprudence, and Practice of Medicine were duly submitted by the Secretary and referred to the Committee of Publication.

#### REPORT ON NOMINATIONS.

The Nominating Committee submitted the following recommendations for officers in addition to those reported yesterday:

Assistant Secretary—Dr. E. W. Brush, New York.  
Committee of Arrangements—Drs. Thomas F.

Rochester, J. F. Miner, E. R. Barnes, C. C. Wyckoff, M. B. Follnelle, W. C. Phelps, E. W. Brush, all of New York.

Committee of Publication—Drs. W. B. Atkinson, T. M. Drysdale, A. Fricke, S. D. Gross, C. Wistar, R. J. Dunglison, of Pennsylvania, and William Lee, of the District of Columbia.

Treasurer—Dr. R. J. Dunglison, of Pennsylvania.

Librarian—Dr. William Lee, of the District of Columbia.

Committee on Library—Dr. Johnson Eliot, District of Columbia.

Members of Section of State Medicine and Public Hygiene—Drs. J. Cochran, Alabama; A. M. Carrigan, Arkansas; W. F. Cheney, California; C. Denison, Colorado; C. A. Lindsley, Connecticut; William Marshall, Delaware; T. Antisell, District of Columbia; J. P. Logan, Georgia; H. A. Johnson, Illinois; T. M. Stevens, Indiana; A. G. Field, Iowa; D. W. Stormont, Kansas; S. Branders, Kentucky; S. M. Brennis, Louisiana; E. F. Sanger, Maine; C. H. Ohr, Missouri; H. I. Bowditch, Massachusetts; H. P. Baker, Michigan; C. M. Hewitt, Minnesota; Wirt Johnston, Mississippi; J. W. Trader, Missouri; M. W. Russell, New Hampshire; E. M. Hunt, New Jersey; E. Harris, New York; J. Comegys, Ohio; B. Lee, Pennsylvania; E. M. Snow, Rhode Island; R. A. Kinlock, South Carolina; Z. A. Atchison, Tennessee; A. E. Carothers, Texas; I. L. Cabell, Virginia; L. C. Butler, Vermont; John Frissell, West Virginia; E. S. Griffith, Wisconsin; G. W. Belton, Florida; C. J. O'Hagan, North Carolina; John S. Billings, United States Army; Joseph Wilson, United States Navy.

Committee on Neurology—Chairman, Dr. J. M. Toner, District of Columbia; Secretary, W. H. Ross, District of Columbia; Members, Drs. J. W. Barclay, Alabama; T. E. Murrell, Arkansas; Martin Baker, California; G. W. Russell, Connecticut; L. P. Bush, Delaware; W. W. Johnson, District of Columbia; T. S. Hopkins, Georgia; J. H. Hollister, Illinois; J. Moffat, Indiana; S. P. Thrall, Iowa; L. P. Yandell, Sr., Kentucky; S. C. Gordon, Maine; A. L. Morris, Massachusetts; D. J. McKern, Missouri; W. W. Breakey, Michigan; E. C. Cross, Minnesota; A. J. Steele, Missouri; John Blaine, New Jersey; N. J. Pittman, North Carolina; J. Jones, Louisiana; George M. Smith, New York; George Mitchell, Ohio; W. C. Warriner, Oregon; H. C. Wood, Pennsylvania; C. W. Parsons, Rhode Island; A. N. Pally, South Carolina; J. B. Lindsley, Tennessee; J. H. Stalnaker, Texas; W. D. Hooper, Virginia; Darus Mason, Wisconsin; O. F. Fassett, Vermont; P. F. Whitehead, Mississippi; W. L. Schenck, Kansas; L. G. Hill, West Virginia; R. W. Hazlett, United States Army; J. Wilson, United States Navy.

Judicial Council—Drs. J. K. Bartlett, Wisconsin; F. Staples, Minnesota; E. Grissom, North Carolina; W. F. Robertson, —; S. Lilly, New Jersey; W. M. McPhutres, Wisconsin; and A. Z. Woodward, Vermont.

The foregoing in place of the seven whose term of office expires at this meeting by constitutional limitation. Dr. P. O. Hooper, Arkansas, in place of Dr. A. Dnulap, whose term expires in 1878.

Committee on Prize Essays—Drs. E. M. Moore, T. Lothrop, W. Miner, H. R. Hopkins, and E. W. Dean, Buffalo.

The report was adopted.

#### REPEALING THE TARIFF ON QUININE.

A series of resolutions were introduced by Dr. J. W. Singleton of Paducah, Kentucky, indorsing the

Morrison bill in Congress in declaring that quinine should be relieved of the tariff imposed upon it, and were unanimously passed.

Dr. H. M. Smith, of Philadelphia, introduced resolutions expressing the regret of the Association at the illness of the former President, Dr. George B. Wood, and extending sympathy to him in his illness.

Dr. J. W. SINGLETON, of Kentucky, introduced a resolution expressive of the satisfaction felt at the unanimity fast coming to exist between the profession in the North and South, which was seconded by Dr. Grissom, of North Carolina, and unanimously adopted by the Association.

Dr. Edward Seguin, of New York, was made Chairman of the delegation to attend the International Convention to be held in Geneva; and Dr. Lewis A. Sayre was elected delegate to the British Medical Association.

Thanks were tendered to Francis Gurney Smith, for his efficiency in transacting the duties of Chairman of the Committee of Publication, from which position he has retired, after many years' service.

A similar compliment was paid to the retiring Treasurer, Dr. Caspar Wistar.

An amendment to the Constitution was introduced making provision for the formation of a

#### SECTION ON OPHTHALMOLOGY AND OTOTOLOGY.

It went over under the rule.

#### RECOMMENDATIONS CONTAINED IN THE PRESIDENT'S ANNUAL ADDRESS.

Dr. BOWDITCH at this point resigned the chair, and took up the subject of the recommendations in his annual address, which had, at a previous session, been laid upon the table, through a motion to refer them to a committee. He deplored the system now existing for publishing the papers presented at the various sections. Many of them were published without being read, and were not fit to be published at all. He regretted this state of affairs exceedingly, and especially that such publications should be permitted to go abroad. He submitted the following resolution:

"Resolved, That the Association recommend to the Chairmen of the Sections, at any place at which we may hereafter meet, the propriety of obtaining from our ablest associates in various parts of the country papers to be presented to the Sections, and that due notice of the names of the writers be given in the medical journals before the meeting."

He moved also that all papers to be published be submitted to the examination of experts whose names should be unknown, and only the most worthy should be published.

These resolutions elicited general discussion and numerous amendments.

On motion of Dr. JAMES P. WHITE, of Buffalo, the entire matter was referred to a committee of five, to report at the next annual meeting, of which committee Dr. Bowditch and Dr. N. S. Davis were to constitute two members.

Dr. WOODWARD moved the adoption of the following resolution:

"Resolved, That from this meeting and hereafter the practice of printing in the Transactions of the Association the so-called verbatim reports of the debates in the Sections be discontinued, and that the reports of the Sections be limited to the papers presented and recommended by the Sections for publication, and such minutes as may be actually read before the Section." Adopted.

DR. HILDRETH, of West Virginia, moved that no paper be referred to the Committee on Publication unless it had actually been read before the Section. Laid on the table.

A communication was read from members of the profession in Buffalo, expressing satisfaction at the decision of the Association to hold its next meeting in that city, and promising hospitality.

DR. BOWDITCH resumed the chair, and DR. BRODIE, of Michigan, submitted resolutions, tendering thanks to the people of Chicago for their hospitality during the present meeting, to the Committee of Arrangements, etc.

Pending the adoption of these resolutions, DR. WOODWARD, of Washington, made a few remarks pleasantly eulogistic of the city of Chicago and its citizens.

DR. E. R. SQUIBB rose to a question of privilege regarding the disposal of his report upon the U. S. Pharmacopœia.

On motion, made by DR. TONER, of Washington, Dr. Squibb was permitted to withdraw his report.

PRESIDENT BOWDITCH invited the President-elect, DR. T. G. RICHARDSON, of Louisiana, to a seat upon the platform, and then delivered his retiring address. He thanked the Association for the distinction it had conferred upon him the past year, and closed his remarks by congratulating the Association upon the era of good feeling at present existing between all sections of our country. "Last year South Carolina extended her right hand of fellowship to Massachusetts, and this year Massachusetts extends her hand to Louisiana." "God bless the Union, and let all the people say Amen!"

The act of hand-shaking between Dr. Bowditch and Dr. Richardson was greeted with a burst of applause.

DR. RICHARDSON made an appropriate response, and as he remarked that God was to be praised that we were again an "unbroken National family of States," the applause was most hearty. He thanked the Association for the honor it had conferred upon him.

The Association then adjourned to meet in Buffalo, N. Y., the first Tuesday in June, 1878.

#### SECTION ON THE PRACTICE OF MEDICINE.

DR. P. G. ROBINSON, of Missouri, Chairman.

DR. B. A. VAUGHAN, of Mississippi, Secretary.

TUESDAY, JUNE 5, 1877.—FIRST DAY.

The Section met at 3 P.M., and was called to order by the Chairman.

##### TREATMENT OF CROUPOUS PNEUMONIA.

In absence of DR. A. B. PALMER, of Ann Arbor, Mich., the author of a paper upon the above subject, it was read by DR. N. S. DAVIS, of Chicago.

The paper principally dealt with the effects of quinine in the treatment of acute pneumonia. After detailing the nature of the disease, and describing the various methods of treatment, Dr. Palmer submitted his particular method. When called to a patient within twelve or twenty four hours after the chill, or at any time before any considerable exudate has occurred, he immediately gave from six to ten grains of quinine, together with from one-fourth to one third of a grain of morphia, which almost invariably, in a short time, from half an hour to two hours, induced copious perspiration and a reduction of the temperature. When he repeated the quinine in doses of from four to

eight grains once in from two to three hours, and unless all pain and special uneasiness was relieved, he added another but usually a smaller dose of morphia in four or six hours, but by all means continuing the quinine in one of the last-mentioned doses until from thirty to fifty, and sometimes sixty, grains were given. Sometimes from twenty to twenty-five grains would be sufficient, given in these divided doses, or, if preferred, in doses somewhat smaller, but more frequently repeated. But as the large quantity was harmless and might be needed, he preferred to give at least thirty, and oftener as much as forty grains in from twelve to twenty-four hours. The effect desired, and certainly as a rule produced, was a decided reduction of temperature, a marked diminution in the frequency of the pulse, a decided moisture of the skin, or free sweating, a slower and more easy respiration, a relief from pain and the feeling of fulness in the chest, a diminution of the cough and of the tenacious and bloody character of the expectoration, and, in short, not only was there a checking of the fever, but of all the evidences, general and local, of the pulmonary engorgement and inflammation, and the quantity of the medicine to be given depended much upon the completeness of the effects produced. The slight deafness and ringing in the ears, which might or might not result from these doses was a matter of very little consequence, was almost always temporary, and should not influence the quantity given. A small quantity of quinine would produce these phenomena with some, while large doses would fail to do so with others, and neither in pneumonia nor in ague were they the measure of the medicinal effect of the remedy or an index of the quantity that would be required or borne. As a rule, all the treatment required after this was a gentle laxative, or, if the tongue was much coated, a few grains of blue mass, followed in a few hours by a mild saline cathartic, and that in turn followed by some mild climative mixture.

Discussion followed, and was participated in by Drs. Gallagher, of Pennsylvania; Hibbard, of Indiana; Scott, of Ohio; Murphy, of Cincinnati; Rooker, of Indiana; Yandell, of Kentucky; Todd, of Indiana; Carpenter, of Iowa, and Bailey of Kentucky.

It is easy to imagine a line of discussion which might be pursued upon this subject, and so it was that blood-letting, tartar emetic, cold baths, Ziemssen's Cyclopædia and all its dangerous and beneficial teachings were thoroughly canvassed. The opinion seemed to prevail that uncomplicated pneumonia in an otherwise healthy subject had a tendency to recovery.

DR. JOHN MORRIS, of Maryland, then read a paper upon

##### "THE EFFECTS OF REMEDIES IN SMALL DOSES,"

in the course of which he deduced the following: First, that the true physiological effect of remedies might best be obtained by the administration of small doses frequently repeated [doses of calomel, iron, quinine, digitalis, tartarized antimony, ipecac, opium, gelseminum, squills, ergot, etc.]; second, that medicines thus given were accumulative in their operation; third, that the effect of remedies is greatly increased by combination, the manner of preparation, the time and mode of administration, etc.; fourth, that large doses of medicine frequently acted as irritants, that they produced an abnormal state of the blood, as was evidenced by such conditions as narcotism, alcoholism, iodism, ergotism, bromidism, etc.; fifth, that more special attention should be given at the bedside to the influence of remedial agents, to the end that a greater certainty may be exercised in their prescriptions.

Dr. Morris asked that he might be allowed the privilege of printing this paper in any medical journal he might select as having been read before that Section of the Am. Med. Association. The request was granted.

The Section then adjourned.

WEDNESDAY, JUNE 6, 1877.—SECOND DAY.

The Section was called to order at 3 P.M., by the Chairman, Dr. P. G. Robinson.

#### NEW INSTRUMENT.

DR. H. I. BOWDITCH, of Boston, exhibited a mechanical appliance consisting of bands so arranged as to keep the head and chest in a favorable position during violent attacks of asthma. Dr. Bowditch mentioned a number of cases in which this appliance had been of great efficiency. The inventor of the apparatus was Dr. George E. French, of Portland, Me. Dr. Squibb, of Brooklyn, moved that a cut of the apparatus exhibited by Dr. Bowditch be inserted in the volume of Transactions.

#### REPORT ON CLINICAL AND METEOROLOGICAL RECORDS, BY DR. N. S. DAVIS, OF CHICAGO.

DR. DAVIS explained that the object of this work was to get at the actual etiology of acute diseases, a subject of which very little was known. It was sought to determine the relation between meteorological conditions and the origin of disease. He gave the figures in the case of bowel disease, by way of showing what the work was. In his own practice, in 1875, he had one hundred cases of bowel complaint, of which fourteen began in June, sixty-eight in July, eleven in August, and seven in October. The mortality tables showed that the deaths from bowel complaints were about alike in July and August. This discrepancy was explained by the fact that many persons who were taken sick in July do not die till August. In the same month of 1876, he had ninety-three cases of bowel complaints. Fifteen began in June, of which nine were diarrhoea, five cholera morbus and infantum, and one was dysentery. Fifty-five began in July, of which twenty-eight were diarrhoea, fourteen cholera morbus, and thirteen dysentery. Twenty-three began in August, of which two were diarrhoea, four cholera morbus, and seventeen dysentery. Dr. Davis read corresponding figures from Davenport, Omaha, and Cairo. In these four cities, there were in the practice of the physician reporting, in 1875, two hundred and ninety cases of bowel complaint, of which forty-four began in June, one hundred and fifty in July, sixty-seven in August, and twenty nine in September. Not a case began in the other eight months of the year. In 1876 the observers in three of the cities reported one hundred and sixty-nine cases, of which all but four cases began in the four months named. Of the one hundred and sixty-five cases in those four months twenty-one began in June, eighty-three in July, forty-three in August, and eighteen in September. The figures showed that more than half the cases in this climatic zone began in July.

Omitting cases of dysentery, there were in 1875, in four cities, two hundred and twenty-nine cases of bowel complaint, of which thirty-seven began in June, one hundred and thirty-two in July, forty in August, and fourteen in September. Of the sixty-one cases of dysentery, seven began in June, eighteen in July, twenty-one in August, and fifteen in September. In 1876, omitting dysentery, there were one hundred and twenty-two cases, of which twenty-four

began in June, sixty-five in July, twenty in August, and thirteen in September. Of the forty-seven cases of dysentery, one began in June, eighteen in July, twenty-three in August, and five in September. It would appear from these facts that the causes operating to produce diarrhoea, cholera morbus, and cholera infantum began in June and attained their maximum development in July, while the causes of dysentery attained their maximum in August. The causes of these diseases depended for their activity on conditions found only in the warm months.

Looking more particularly into the dates of the cases under examination Dr. Davis showed that of the fourteen cases in his practice in this city in June, 1875, all began after the 19th of the month. Of the forty-four cases in the four cities beginning in June, 1875, only five began earlier than the 19th. His conclusion was that the bowel affections, so characteristic of this temperate climate, began invariably with the first week of continuous high temperature, and that every subsequent occurrence of several days and nights of continuous high temperature caused new attacks to be increased in number throughout the month of July, less in August, and still less in September; that it was not simply the extreme of heat, but its duration, which determined the number of attacks; that this continuous high heat, to be efficient in producing these affections, must follow a protracted season of cold; and that, if we compared these deductions directly with statistics of mortality, we should find them to conform in every particular in that the high rate of mortality followed exactly the same line. That fact was regarded, as one of great importance in connection with sanitary measures which were to be adopted for the protection of life in infants; preventive measures must strike with the first week of consecutive high temperature. These conclusions were corroborated by quotations from mortality tables.

#### INFLUENCE OF COLORADO CLIMATE ON CONSUMPTION.

DR. CHARLES DENISON, of Colorado, continued the report made last year upon the above subject, by citing the history of several cases of consumptives who had been benefited by a residence in high altitudes. Dr. Denison's argument gave a large amount of statistical information concerning the history of Colorado as a sanitarium. A very full record of six unfavorable and six favorable phthisical cases was given by way of illustrating the effects of the climate upon patients differentiated by variety of affection. The conclusion reached by the essayist most interesting to the general public would seem to be, that he believed the generally-accepted idea that consumption could only be successfully treated climatically during its first stages was not an absolute truth. "The truth was, the systemic influence of extensive disease in the first was often much greater than slight incursions of phthisis in the third stage." The favorable influence of high altitudes in phthisis was best shown in the incipency of chronic inflammatory and hemorrhagic cases, and in others in proportion as these were characteristic. The unfavorable influence of high altitudes in phthisis was shown as the disease approached or was complicated with the following conditions: Cardiac disease associated with increased labor and abnormal activity; the stage of "softening" in acute cases (especially with uniformly rapid pulse and high temperature) associated with extensive deposit, variable nervous state and lack of courage to do, in order to be well.

DR. BOWDITCH, of Boston, regarded it as unadvisable to send patients away from home who had reached certain stage of phthisis. In cases in which the disease

was not far advanced change of climate might be beneficial.

DR. ULRICH, of Pennsylvania, believed the greatest benefit would come from a radical change in the surroundings of the patient, both mental and physical, and that such change could be effected at home.

DR. BENTON, of Cleveland, favored the high altitude of Colorado because it was inhabitable. Other high altitudes might not be inhabitable.

DR. KINGSLEY, of St. Louis, referred to the fact that patients went from St. Louis to Colorado, improved considerably, returned, and shortly after their return died because of the rapid development of the disease. The paper was further discussed by Drs. Scott, of Ohio, Heddens and Kingsley, of Missouri, and Steeman, of Ohio. The report was referred to the Committee on Publication, and the Section adjourned.

#### THURSDAY JUNE 7, 1877.—THIRD DAY.

The Section was called to order at 3 P.M. Dr. P. G. Robinson, Chairman, in the chair.

#### REPORT OF THE COMMITTEE ON BOVINE VACCINATION. BY DR. H. A. MARTIN, OF MASSACHUSETTS, CHAIRMAN.

The report was entirely the work of one member of the committee and he alone was responsible for what was said. The report was divided into sections embracing a historical account of animal vaccination; description of animal vaccination; alleged disadvantages; statistics; peculiarity of animal vaccination; advantages of animal vaccination; and suggestion regarding the proper method to make animal vaccination accessible to the profession gratuitously, instead of the matter of bargain and sale, as it is at present. Animal vaccination was introduced by Dr. Martin in the year 1870.

The alleged disadvantages had been:

1. That it was dangerously violent; that was an incorrect statement. It was also exempt from erysipelas.
2. Communication of other diseases. There was no authentic case in which disease had been communicated except herpes circinatus.
3. That it did not take easy. That was not true.
4. That it did not keep well. Animal virus would keep for an indefinite length of time.
5. Vaccination with living lymph was an uncertain process. That objection was believed to be groundless, and that vaccination with fresh animal lymph, if properly managed, need not fail.
6. It was expensive. That should not be so, and the government should establish stables and furnish an unlimited supply gratuitously.

The alleged advantages were:

1. An unlimited supply of virus could be furnished with exceptional security.
2. Impossibility of contamination from disease.
3. It was always protective when vaccination and revaccination were practised. Humanized virus was not always protective.

The report was referred to a special committee consisting of Drs. Bowditch, Wheeler, and Wigglesworth, of Boston.

#### THE RECOGNITION AND MANAGEMENT OF THE GOUTY STATE IN DISEASES OF THE SKIN.

DR. L. D. BULKLEY, of New York, read a paper upon the above subject, in which he desired, from a clinical stand-point, to impress upon the minds of the profession the value and necessity of recognizing the gouty state in many diseases of the skin. The subject was considered under three heads:

1. The importance of recognizing certain skin diseases which are the early manifestations of gouty disease:

2. The importance of recognizing the gouty state in connection with certain diseases of the skin.

3. Management of the gouty state, especially in the early period when the skin lesions are most apt to manifest themselves.

The evidence of the gouty state was considered in detail.

The paper was discussed by Drs. Hibbard, of Indiana; Cabell, of Virginia; Scott, of Ohio; Ulrich and Duhring, of Pennsylvania. The paper was referred to the Committee on Publication.

#### CHRONIC DISEASES OF THE RESPIRATORY SYSTEM.

DR. F. N. DAVIS, of Chicago, reported the result obtained by analysis of 365 cases of chronic pulmonary disease which had fallen under his observation during the year 1875. The report was referred to the Committee on Publication.

It was discussed by Drs. Scott, of Ohio; Lester, of Missouri; Waterman, of Indiana; Ulrich and Gallagher, of Pennsylvania.

The following papers were read by title and referred:

Therapeutics of Cancer, by Dr. Theodore A. McGraw, of Detroit.

Climatic Resorts of Europe and America Compared, by Dr. George E. Walton, of Cincinnati.

The Section then adjourned.

#### SECTION OF OBSTETRICS AND THE DISEASES OF WOMEN AND CHILDREN.

DR. JAMES P. WHITE, of Buffalo, Chairman.

DR. ROBERT BATTEY, of Georgia, Secretary.

#### TUESDAY, JUNE 5, 1877.—FIRST DAY.

DR. BYRD, of Illinois, presented a paper, which was read by Dr. Battey,

#### ON SOME OF THE DISEASES REQUIRING DILATATION OF THE FEMALE URETHRA.

A number of cases were cited. The first was that of a vascular growth entirely surrounding the meatus of the urethra. It had been treated as a stricture. With the *cérascur* and scissors, a small vascular growth was removed without difficulty. Subsequent dilatation of the urethral canal entirely cured the urethrisms. The case was illustrated by drawings of the parts, with the growth *in situ* and after removal.

Other cases were cited to illustrate the method and ease of dilating the female urethra, for vesical tenesmus, etc.

In the discussion, Dr. MARCY, of Massachusetts, said that in one case he had removed a growth as large as a cherry. The removal was not dangerous, and three years had elapsed without a recurrence.

DR. SMITH, of Iowa, had removed such growths in two cases with the scissors, without difficulty or danger.

DR. JENKS, of Michigan, remarked that in all instances these growths should be removed, and that no complicated instruments were needed to dilate the female urethra. He used conical rectal bougies of different sizes, until the finger could be easily passed.

DR. JACKSON, of Chicago, thought it often difficult to find these flat and but slightly elevated growths within the urethra. To facilitate the diagnosis and removal, he used a conical glass speculum, with a fenestrum, into which the growth dropped. The

base of the growth he usually touched with fuming nitric acid.

DR. MARCY, of Massachusetts, said that he had always used the method and speculum spoken of by the last gentleman, thinking that was the usual procedure.

DR. KIMBALL, of Massachusetts, presented a paper, read by Dr. Martin,

#### ON EXTIRPATION OF THE UTERUS.

After giving an account of the early history and results of the operation, and considering in detail the observations of Péan and Caternault, the writer proceeded to examine the question, Is the operation ever justifiable? It was a sad comment that nearly nine in ten cases resulted in death. In Scotland all cases were fatal except the three successes of Keith. Death was caused by shock, hemorrhage, inflammation, and septicaemia.

A case was detailed which the reader said might be called a specimen case. A woman had presented herself to him with a hard, movable tumor, measuring seven or eight inches in its longest diameter, which was easily recognized as an interstitial fibroid. The patient was sent away, and told that nothing could be done for her. Two years afterwards she returned, but so changed that she was not recognized, nor was the diagnosis of the tumor at that time made out. The patient insisted upon an operation, which was undertaken under the conviction that the tumor was as likely to be ovarian as uterine. Upon opening the abdomen an unusual appearance was presented by the omentum, which had never before been met with by the writer, namely, innumerable cysts, varying in size from a robin's egg to a pea, everywhere studded the omentum. The omental mass was strangulated and cut off. The entire uterine mass was then removed; it weighed thirty-one pounds. The long pedicle was stitched into the lower end of the abdominal incision. Recovery was perfect at the end of the twelfth week.

Without denouncing the operation, it was one which was justifiable only in extremely rare instances. During a period of twenty years it had seemed to him justifiable in but two or three instances. Undoubtedly it was most often performed on account of an error in diagnosis.

DR. MARTIN, of Massachusetts, spoke of the noted New England case, in which it was not known till after the operation that the uterus had been removed; the operation was recovered from.

DR. KIMBALL, of Massachusetts, feared it might look like vanity, but the first operation which he did in 1853 was the first, so far as he knew, which was undertaken deliberately, the diagnosis being established. Altogether, he had operated twelve times, with six recoveries. One was an instance of pedunculated fibroid, and in another instance the uterus was amputated through its body. Trenholme has once removed the uterus on account of the rupture of a cyst, with symptoms of septicaemia; the woman died.

The writer spoke of one class of cases in which the operation was especially contraindicated; those in which the growth of the tumor was downward, occupying the pelvic excavation.

DR. REAMY, of Ohio, alluded to a series of five cases belonging to Dr. Thos. Wood, of Ohio, in which there were three recoveries.

DR. SMITH, of Iowa, had once performed the operation under an error in diagnosis. A trocar was driven into the intumescence which drained away some two ounces of amber-colored liquid; it was thought to be

from an ovarian cyst, and gastrotomy was performed. The tumor was found to be uterine, and the mass was removed; it weighed fifteen pounds. Upon the upper surface of the growth a collapsed cyst was found into which the trocar entered. The woman died on the sixth day.

DR. SIMS, of New York, regarded the paper a valuable contribution to the literature of the subject, and its appearance now as most timely, especially as some were carried away with the idea that the operation should be performed much more often. He believed the operation was sometimes justifiable; but was not always so in Péan's cases. He since had performed the operation three times; in two instances the patients died of shock, and the third woman died of septicaemia; in this case there was sloughing of the broad ligament, and some eighteen ounces of pus were found in the abdominal cavity.

DR. JENNINGS, of Arkansas, inquired of Dr. Kimball, what percentage of cases died of septicaemia.

DR. KIMBALL, of Massachusetts, replied that peritonitis and septicaemia usually coexisted. One case died from hemorrhage; the rest died from peritonitis and septicaemia. In one case there was a most singular manifestation of septicaemia. The patient had survived three weeks, when a lump appeared in one parotid region, which grew so rapidly that the poor woman was asphyxiated.

DR. MARCY, of Massachusetts, asked him how long after the recovery did the patients live.

DR. KIMBALL, of Massachusetts, replied that so far as he knew they were all now alive, except in one instance. In one case he had removed an ovarian tumor eleven years before ablating the uterus. In another subject he removed the ovaries with the uterus.

DR. ATLEE, of Pennsylvania, remarked that he was physically unable to take part in the discussion of this interesting subject, but he wished to say that, in his opinion, the operation should never be performed save when death was inevitable, and always as a *dernier resort*.

DR. BYFORD, of Illinois, believed the operation was never justifiable except as a last expedient; and before deciding that the operation should be performed in a given case we should separate the cases in which death is really imminent from those in which it is only apparently so. For instance, it was well known that these uterine tumors were often the seat of inflammation, when it would seem that the patient's life was endangered; but inflammation was a process by which nature lessened the tumor, sometimes caused it to disappear, and was often recovered from. The danger of death from exhaustion, and especially from pressure upon the neighboring vital viscera, were among the indications which might justify the removal of the uterus.

DR. GRANT, of Canada, had listened with great pleasure to the paper and the discussion. So far as he knew, the opportunities for observations upon this subject had been extremely rare in Canada. He had known of but two cases—one followed by death, and one followed by recovery.

DR. MARY THOMAS, of Indiana, knew of one instance of recovery from removal of uterus, but thought the operation should be resorted to with great hesitation.

DR. WHITE, of New York, rose to thank Dr. Kimball for his very able paper; very few men, however, who had had such success were as modest. In other words, the success attained by Dr. Kimball hardly warranted the conclusion that the operation was almost never justifiable, which had been expressed by so many present. Why wait till death was inevitable and the patient

was moribund? Why not give the patient the advantage of the only hope at a time when the operation promises most? He believed in going forward. The early ovariologists were greatly opposed, and the whole world was slow in accepting, what had been demonstrated in America, that ovariectomy was a justifiable operation. The operation under consideration had a great future. He declared himself conservative, but not timid. Three cases had occurred in his practice. Some weeks since he was sent for to do the operation, but the order was countermanded because the woman was supposed to be dying. The woman did not die, and he was again sent for and removed an immense fibro-cystic tumor. The woman died from shock. A year earlier the woman might have been saved by the operation. In another case the woman died from exhaustion. The third case was operated upon under an error of diagnosis. It proved to be uterine instead of ovarian, and the uterus was removed through the neck. This woman recovered.

DR. BOZEMAN, of New York, read a paper entitled

KOLPOKLEISIS AS A MEANS OF TREATING VESICO-VAGINAL FISTULE.

Was the procedure ever necessary? The conclusions of the writer were that by a systematic and proper preparatory treatment vesico-vaginal fistula could always be closed by operation without ever necessitating the destruction of the vagina. The paper consisted chiefly of a correspondence between Prof. Simon, of Heidelberg, and the writer, upon a series of cases upon which both had operated in concurrence, in Heidelberg. The reader exhibited his graduated set of vaginal dilators, the systematic use of which distinguished the author's operation.

WEDNESDAY, JUNE 6, 1877.—SECOND DAY.

The Section was called to order at 3 P.M. by the Chairman.

DR. BOZEMAN, of New York, read some statistics in addition to his paper of yesterday. Of twenty-five cases of vesico-vaginal fistula, collected from European journals, eighteen were condemned to kolpokleisis; two died from the operation. The paper was not discussed.

DR. MARCY, of Massachusetts, presented a paper

ON THE CONGENITAL ABSENCE OF THE UTERUS.

Several interesting instances were cited. One, aged 29, had never menstruated; had no pubic or axillary hair; externally was well formed; had no sexual instinct. There was a vagina, but every mode of examination failed to elicit the existence of the uterus. She suffered regularly from symptoms of suppressed menstruation. The woman had two sisters who had similar evidences of this imperfect development. In another case, spoken of in the paper, the woman, aged 32, had no periodic manifestations. In a third instance there was a slight uterine mass, which was threaded, as it were, by the passing sound.

DR. WEBBER, of Indiana, had recently seen a woman, married for two years, who had never menstruated, and in whom he could find no signs of a uterus.

DR. STAPLES, of Minnesota, had recently dissected a fully grown fœtus, whose external parts appeared those of a female. There was no vagina and no uterus; ovaries were present; no anus; the intestine ended in the bladder.

DR. WARNER, of Massachusetts, had met with an instance in which neither vagina nor uterus existed. The woman was otherwise perfectly formed.

DR. SIMS, of New York, had met with five cases; but, unlike Dr. Marcy's case, the vagina in every instance was wanting. In all instances the subjects seemed perfectly formed; and one particularly was a beautiful woman. But, in all instances, the uterus and vagina were absent. In one instance the subject was madly in love; but marriage was, of course, interdicted. In regard to the sexual instinct, the speaker said he had now been in practice forty-two years, and had never been guilty of asking a woman if she experienced the sexual desire.

DR. DEAN, of New York, spoke of the liability of error in deciding that there was no uterus. A case was detailed, that of a girl, aged 15, who had not menstruated. The vagina was imperfectly formed, but not positively wanting. The entire staff of the Rochester hospital agreed that the uterus was absent. Subsequently an ill-defined tumor was felt above the symphysis pubis. An incision was made upward in the direction of the vagina which revealed an os and a uterus, from which drained away a quantity of retained menstrual matter. The girl has since menstruated.

DR. BOZEMAN, of New York, mentioned a case, otherwise perfectly formed, but in which the uterus and sexual instincts were wanting.

DR. SEYMOUR, of Troy, N. Y., mentioned a case in which the uterus was not altogether wanting, but in which the growth of the organ had been early arrested, perhaps by a severe attack of scarlatina, from which she suffered in her childhood.

She had never menstruated, and the sexual instinct and female modesty and shame were entirely wanting. It occurred to him that the uterus might be made to grow; and, with this end in view, stimulating injections were used; soon the uterus began to grow and the woman afterwards began to menstruate. Subsequently her womanly instincts began to predominate, and rather to his detriment; for she blackened his reputation in a large section of his city, by detailing everything that had been said and done to her during her treatment. The speaker protested against its being declared indelicate to ask a woman concerning her sexual feelings, or concerning anything that could throw light upon the case under consideration. Was it more impertinent to inquire about the sexual feelings than to know about the perfectly formed external parts?

DR. PARVIN, of Indiana, had met with one case in which there was no evidence of a uterus. He spoke particularly of a class of cases in which the uterus was not absent but undeveloped. The function of menstruation was sometimes absent and sometimes vicarious. The uterine mass was often no larger than the end of the little finger. Passing the sound into its minute opening was quite "like threading the mass," as Dr. Marcy very aptly said. Such cases were important, because amenable to treatment, and the development of the uterus could sometimes be artificially completed. The speaker confirmed Dr. Sims in his views of the indelicacy of asking a woman concerning her sexual feelings. He knew not how to ask such questions. He was ignorant of the euphony with which to clothe the thought.

DR. BATEY, of Georgia, had seen four cases in which the uterus was apparently absent. In one, the vagina was about an inch and a half long, no uterus was felt; the woman was barren, and had never menstruated.

DR. WHITE, of New York, had seen ten or more such cases. One woman had previously consulted a practitioner because coitus was imperfectly executed.

She was assured that the deformity could be remedied, and submitted to an operation. A hole was made, which satisfied her husband, but she was not able afterwards to hold her water, which was constantly running away. An examination showed absence of vagina and uterus, and a large hole in her bladder. This vesical fistula the speaker closed by operation. In this case, when the finger was passed into the bladder, the ovaries could be easily felt upon both sides. In another case, the creature had been brought to him to be fitted with a truss. He found what appeared to be the labia of the vulva, and one labium contained a testicle, upon which the truss was to be fitted. In still another instance, he found the labia containing testicles—the subject being brought to him to decide whether the creature should be christened George or Georgiana.

DR. BYFORD, of Illinois.—The experience of the gentlemen who had spoken surprised him. He was not before aware that there were so many women in the world without a uterus. Two cases occurring under his observation were spoken of. In each there was an undeveloped uterus. In one, galvanism was tried, without result; the subject was more than thirty years old. In another case the uterus was at first about an inch and a half in length, but it subsequently suppurated and dwindled in size. In all he had seen some eight doubtful cases.

DR. CRAWFORD, of Illinois, mentioned in this connection the case of a child, now eighteen months old, who had menstruated every twenty-eight days for seven consecutive periods. The period was four days in duration. The amount of blood lost was nearly that lost by the adult. In all other respects she was like other infants.

DR. REAMY, of Ohio, mentioned a case in which menstruation had never occurred till the age of 21. By operation a vagina was made and the presence of the uterus made out. He protested against the declaration going out from this body, that it was indelicate or impertinent to ask a woman concerning her sexual tastes. It was our duty to inquire concerning everything which could throw light upon the case under consideration.

DR. CUTLER, of Massachusetts, was requested to exhibit the electrolytic apparatus devised by him for the

#### ELECTROLYSIS OF UTERINE TUMORS.

The success of the operation has been greater since he devised the new grooved electrode. These pointed electrodes are driven into the most accessible part of the mass, sometimes through the abdominal walls, at other times through the vagina or rectum. The electrodes must always be separated from each other by at least a half inch of tissue; more than this was better. The operation should always be performed under ether. The duration of the sitting varied from five to fifteen minutes.

DR. HILDRETH, of West Virginia, exhibited a new

#### VAGINAL SPECULUM

which he had improvised. Its shape was like a common glass speculum, but its walls were made of wires, which ran lengthwise, and were separated from each other by half-inch spaces. The advantage possessed by it is that the vaginal wall could be seen at any point.

THURSDAY, JUNE 7, 1877.—THIRD DAY.

\* The Section was called to order by the President.

DR. SMITH, of Iowa, read a paper on

#### HOW TO DECIDE THE BEST POSITION IN EVERY LABOR.

The reader had been early convinced, by a case of extreme lateral obliquity of the womb, that the position of the woman had much to do with the progress of labor. In every case we should carefully find out the relations of the axis of the gravid uterus to the entrance of the parturient canal, and place the woman in that position which was most favorable to the entrance of the fetus into the pelvis.

DR. PARKER, of Massachusetts, reported a case of a

#### LARGE GROWTH CONNECTED WITH THE CLITORIS,

which was removed. The subject was a prostitute, aged twenty-five years. She had been insane more than three years. It was known that, at least three years ago, the tumor of the clitoris was as large as an orange. It was now much larger. Under ether, the growth was removed, without difficulty, with the *céraseur*. The mass weighed four and a half pounds. Its gross appearances were those of a syphilitic condyloma. Immediately, upon recovering from the effects of ether she was apparently perfectly sane, and remained so. She exclaimed to the operator: "God bless you! Why have you not done this before?" She also said that she had another trouble, namely, her stomach. A fulness over the region had been often noticed. During her stay in the almshouse she had been noticed to vomit frequently. She had a morbid predilection for cabbage, which she would eat in great quantity, and immediately reject.

The patient died three days after the removal of the tumor, though from no effects of the operation.

An autopsy revealed the stomach nearly full of hay, rolled in a large circular mass, and one large ball had been recently driven through the pyloric orifice, which probably caused death.

Photographs were shown of the tumor *in situ*, and of the stomach on section, containing the hay.

DR. WHITE, of New York, completed the reading of his Annual Report on Obstetrics and Gynecology, which had been presented at the morning session of the Association. The reader dwelt particularly upon the treatment of inversion of the uterus by gradual reposition. By means of the appliance devised by him, the reader said that all inverted uteri could be replaced, no matter the length of duration of the inversion—thirty years or six months.

The paper concluded with a plea for bedside instruction in obstetrics; which system the speaker instituted in this country more than thirty years ago.

DR. SIMS, of New York, contrasted the infrequent use of the forceps in labor years ago with the humane use of the instrument at this time. Some years ago, Dr. Quackenbush, then quite a young man, startled the New York State Society by saying that he had used the forceps in fifteen hundred labors. This was perhaps the beginning of the frequent use of the instrument, which now prevailed in this country, but to no such degree abroad. The speaker alluded to a paper by Dr. Newman, of Denver, in which the use of short forceps was advocated in the last stage of labor. A very short forceps was exhibited which the speaker thought (erroneously) was devised by Dr. Newman to be used in the last moments of labor.

DR. QUIMBY, of New Jersey, spoke against such frequent use of the forceps; it was meddling and dangerous midwifery. The case should be left to nature for at least six or eight hours. The forceps should only be used when nature shows signs of failing.

DR. FAIRBANKS, of Michigan, remarked that no ignorant practitioner should be entrusted with the use of the instrument. Thirty years ago a practitioner

would have been condemned, and called a butcher, if he had used the forceps.

DR. JENKS, of Michigan, said it was no argument against the use of an instrument that in the hands of unqualified men it could do harm. He should be sorry if the teaching now prevailed of waiting, as was taught formerly. When the parts were ready for delivery there could be no advantage in waiting. Under these circumstances delay in delivery was an indication for the use of the forceps.

DR. REAMY, of Ohio, said the time had gone by for measuring the powers of nature by the watch. The intelligent practitioner should be ready to interfere at any moment and at any stage of the labor. Damage to the woman and child was caused much more often by too great delay than by the too early use of the forceps. The speaker said of the particular forceps now before the Section that it possessed many faults, which he pointed out, and concluded by saying that it was a beautiful instrument, but at the same time it was a useless thing—a mere toy.

DR. WOODWARD, of Vermont, also thought the instrument in question a useless instrument, and spoke of the advantages of the Hodge forceps. He was formerly taught to use the forceps to save the child; but he also used it now to save the woman's bladder, which he did by its early use.

DR. BATEY, of Georgia, said that it had been claimed as an advantage that the forceps could be applied without the knowledge of the woman. He had more than once been guilty of asking the question which had been so severely condemned yesterday, but he had never used the forceps clandestinely.

DR. BYFORD, of Illinois, said that in his practice, when the pains failed and the head did not advance, he interfered without reference to time. He wished to defend the little instrument which had been so severely abused. The criticisms made by Dr. Reamy might apply to Dr. Newman's forceps, but the instrument now exhibited was not Newman's forceps, but Sawyer's forceps, which was a modification of Newman's, and a hundred per cent. better than the original. He had seen the instrument in actual use, and its excellence was very apparent. He had no hesitation in saying that, for the class of cases which the author had in mind, it was the best short forceps in the world.

DR. GARRISH, of Indiana, protested against such teaching going out from this body, advising such frequent use of the forceps. During a practice of twenty-five years, in but ten or twelve cases did he use the forceps. The instrument should be reserved for those cases in which nature had failed.

DR. SIMS, of New York, was especially asked to give his views on

#### STENOSIS UTERI.

The speaker detailed the history of the surgical treatment of the affection. Simpson was its author, who claimed that no damage resulted from the operation; but in two weeks from its introduction in New York, two cases of dangerous hemorrhage had resulted in his practice. Subsequently, when the speaker visited Edinburgh, he found that accidents did occur, even in the hands of the great master himself.

As first performed, the operation consisted in cutting through the vaginal cervix upon both sides with a metrotome. Soon after he began to do the operation, a case presented itself to his notice, of extreme retroflexion, that admitted the sound with the greatest difficulty. It occurred to the speaker to amputate the posterior lip of the cervix, which was greatly

elongated, and with the knife to cut along the posterior aspect of the cervical canal. This was the origin of the operation, which was known as Emmet's operation, and which he wished to be known as Sims's. In the operation which he now performed, the knife was used, and the scissors were discarded. If the lips of the cervix were symmetrically developed, the lateral incisions were made with the knife; but if the posterior lip was elongated the posterior incision was made. The depth of the incision varied with the size of the neck; the substance was cut nearly two-thirds through.

The speaker was particular to guard against all possibility of hemorrhage, by tamponing the cervix with cotton soaked with liq. ferri subsulphas 1 part, water 2 parts. The success of the operation depended upon the subsequent dilatation of the cervix. All operations would be futile unless a systematic dilatation of the cervix was carried out.

DR. PARVIN, of Indiana, reminded the Section that other matters were treated of in Prof. White's paper that merited discussion. In regard to the induction of premature labor in cases of placenta previa, he wished to say that, in his opinion, the procedure should never be resorted to, save when the child was visible and the woman in great danger from imminent hemorrhage.

DR. SEELEY, of Illinois, exhibited

#### A NEW CERVICAL DILATOR.

It consisted of a silk bag outside of a rubber sack. Any shape could be made which was desired. A tube was carried into the sack to its fundus for the purpose of holding a metallic sound, by means of which the dilator was held within the cervical canal to be dilated. Another tube connected the body of the dilator with the syringe by means of which the dilator was distended. A disadvantage possessed by the Barnes dilator was that it slipped out of the canal; in this instrument a sound secured its retention.

DR. SIMS, of New York, exhibited Fowler's pessary, which the speaker called almost a universal pessary. In principle it was like the Hodge, but was much more bulky, being a deep, cup-like shell of vulcanite.

DR. FRENCH, of Illinois, pointed out several defects possessed by the instrument, chief of which was its great bulk. Its large surface bearing upon the vagina would do injury to the part. The opening in the anterior part of the instrument, to facilitate its removal, was a fault; because through it there was danger of the soft parts prolapsing and becoming strangulated.

The Section then adjourned.

#### ARMY NEWS.

*Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from June 3 to June 9, 1877.*

GRAY, C. C., Surgeon. To report in person to the Commanding General, Dept. of the Missouri, for assignment to duty. S. O. 119, A. G. O., June 4, 1877.

HALL, W. R., Asst. Surgeon. To accompany the troops withdrawn from Alaska, and upon his arrival at Fort Stevens, Oregon, report to the Post Commander for duty as Post Surgeon. G. O. 13, Dept. of the Columbia, May 23, 1877.

CORBUSIER, W. H., Asst. Surgeon. Assigned to duty at Chattanooga, Tenn. S. O. 111, Dept. of the South, June 5, 1877.

## Correspondence.

## OPHTHALMOSCOPE MAKING.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—I hope you will grant me a reply to Dr. E. G. Loring's personal attack, published in your last issue, under the title, "Historical Note on Modern Ophthalmoscopes." It was the loss of time caused by the necessary frequent interchange of the three disks in Loring's first ophthalmoscope, that led me to construct my double-disk instrument, of which the above-mentioned note says such hard words. Yet, not a few expert ophthalmoscopists found it good, and use it still.

The series of 24 glasses which Dr. Loring determined upon is rational, and based as much as is practical, on a refractive interval of  $\frac{1}{3}$ , which by Donders had been used for other purposes. 24 seems about the smallest number of correcting glasses that would meet the requirements of a practiced ophthalmoscopist. It would be easy to put this or a greater number in one disk of convenient dimensions, if the size of the aperture in the mirror could be reduced at will. On this point a series of experiments gave me the result that the best ophthalmoscopic picture is obtained by a mirror aperture of 3.5 to 3.75 millimetres in diameter. (*See Archives of Ophthalm. and Otol.*, IV, p. 31.) This was the basis from which I started in determining the size of the auxiliary glasses, and finding that they could be small enough to put 24 in one row at the periphery of a single disk, I had the instrument made which I described. Since it sufficiently differed from those then in use, in particular from Wecker's, by having another and much simpler mechanism, and from Loring's, by having his *larger series in one row, the glasses centred and covered*, I described it as a new ophthalmoscope, it being, of course, as all the others, only a modification.

The simple and convenient instrument rapidly found favor, and soon afterwards Dr. Loring constructed another single-disk ophthalmoscope, with the same diameter of the lenses, the 24 glasses placed in one row centred by a spring-catch, and covered as in mine, with the only difference that the cover consisted, not in a plate (which would have protected the glasses better), but in a movable ring. This ring leaves all the numbers of the glasses open to view, the great advantage of which, I fail to see; and, "*by making the ring swing vertically we get rid of all loose screws.*"\* There is only one screw in my ophthalmoscope. I have used the same instrument daily for some years, and the screw is not loose yet. Dr. Loring, we all know, gave the subject of ophthalmoscope making thorough consideration, but if he thinks that "*small glasses are optically not so good as large glasses.*" why did he adopt them? It is not inconvenient to have the disk and the glasses somewhat larger, and the reflexes from the disk disappear entirely.

If "*he discarded, in 1869, the spring for centring the glasses . . . ., in order to avoid reflections,*" why did he take it up again later?

If he "*personally prefers to have the posterior surface of the glasses exposed . . . ., to get rid of a source of annoying reflections,*" why did he cover them? Apart from this, I should like to know, how the covering plate could produce reflexes, if the upper aperture were large enough?

And why did Dr. Loring adopt all these arrangements only after he had found out that my single-disk ophthalmoscope was favorably received?

\* This and the following quotations—the italics are mine—are taken from Dr. Loring's "Historical Note." K.

Truly, so long as he does not prove that his single-disk ophthalmoscope, with 24 glasses, was made before mine, I have nothing to take back of what I have written or may have said. H. KNAPP, M.D.  
NEW YORK, 25 W. 34TH STREET, June 10th, 1877.

## Medical Items and News.

CONTAGIOUS DISEASES.—Comparative statement of cases of Contagious Disease reported to the Sanitary Bureau, Health Department, for the two weeks ending June 9, 1877.

June 2 . . . . .	1	9	101	2	47	47	3
" 9 . . . . .	0	3	75	3	62	29	4

DEATH FROM NITROUS OXIDE.—Mr. G. M. Harrison, aged 53, a surgeon in good practice, and formerly Lecturer on Medical Jurisprudence in the Manchester Royal School of Medicine, died on March 27th, while under the influence of nitrous oxide gas, administered for the purpose of having a tooth extracted. Mr. Harrison, it appeared, being unnerved and excited, partly from the suffering he had undergone, and partly from the want of proper food, which the condition of his mouth had prevented him from taking, insisted on the inhalation being pushed until he should snore, and—for at any rate part of the time—held the mouthpiece in his own hand and inspired very vigorously. The first attempt at extraction was made before he was fully insensible, and was abandoned until more of the gas had been given. Two teeth were then removed. Symptoms of syncope ensued after the operation, and the dentist sent for medical assistance. On the arrival of a surgeon, Mr. Harrison was pronounced to be dead. At the post-mortem examination there was found some fat about the heart; the cavities on the right side were distended with blood, while those on the left side were empty. The lungs were gorged with dark blood. All the other organs were healthy.

ANOTHER CASE OF GASTROSTOMY.—M. Lannelongue, of Bordeaux, reports that he has practised this operation under the following conditions: A man who had been suffering from stricture of the œsophagus for six months, found himself utterly unable to swallow any liquid food. Passage of instruments was impossible, and the patient was much enfeebled. Accordingly, gastrostomy was done in pursuance of the plan adopted by M. Verneuil in his successful case. No difficulty was met with in the operation, and the patient was fed for twenty-six days, but pulmonary trouble led to a fatal issue. At the autopsy the disease was found to be epithelioma of the œsophagus, and perforation had taken place into the bronchi. It was also seen that the stomach was perfectly adherent to the abdominal wall. M. Lannelongue therefore gives in his adherence to the view that gastrostomy is a rational operation, believing that it is indicated whenever life is threatened from œsophagia. To insure success, Verneuil's method should be rigidly followed, one of the principal points he lays down being that the stomach is to be firmly fixed to the abdominal wall by the careful insertion of numerous sutures before the artificial opening is made.—*Journal de Médecine*, May, 1877.

## American Medical Association.

### SECTION ON SURGERY AND ANATOMY.

DR. FRANK H. HAMILTON, of New York, Chairman.  
DR. JOHN E. OWENS, of Chicago, Secretary.

FIRST DAY.—TUESDAY, JUNE 5TH.

THE SECTION was called to order at 3 P.M., and the first paper was read by DR. J. T. HODGEN, of Missouri, on

#### THE VALUE OF EXTENSION IN THE TREATMENT OF FRACTURE OF THE FEMUR.

DR. HODGEN described the usual treatment for such a fracture, and pointed out the faults of plaster cases and pulley apparatuses. Lateral supports he pronounced to be valuable only to prevent angling. Continuous extension, by means of force not varying in power, was essential. It was not to be found in elastic extension, the name of which showed that the power could not be constant. Friction vitiated the pulley apparatus; oblique suspension he deemed to be the only suitable method. The exact pressure required could be obtained by varying the obliquity of the suspending cord till the patient was out of pain. In twenty-four hours a child five years old would learn the amount of extension under which comfort could be obtained, and would maintain it. Fortunately, the amount of extension needed was what the comfort of the patient required. The patient would naturally adapt his position to the lessening contraction of the muscles.

The paper set forth the following propositions:

1. That in the treatment of fracture of the femur continuous and equable extension is indispensable to the best result, and is conclusively shown in the impossibility of maintaining with equal certainty accurate coaptation by any other means.

2. That continuous and equable extension cannot be secured by lateral support.

3. Continuous and equable extension can only be secured by suspending the limb, because in no other way can we avoid friction between the extending force and the part to be extended.

4. Suspension furnishes the best means for allowing motion to other parts of the body, while perfect apposition of the fragments of fractured thigh is constantly maintained, because there is no resistance offered to the movement of the limb in any direction in which the body may be moved except in the direction from the point of suspension, and in every other direction the limb follows the movements of the body without the least friction.

The position taken by Dr. Hodgen provoked a spirited discussion, which was participated in by Drs. Celler, of Arkansas; W. H. Hingston, of Canada; Yuesdell, of Rhode Island; Gasley, of Arkansas; Peck, of Iowa; Hevans, of Missouri; Pearce, of Illinois; Egbert, and others.

#### SHORTENING IN FRACTURES.

DR. HINGSTON, of Canada, offered the following, which was adopted:

*Resolved*, That in fractures of the thigh, notwithstanding the judicious employment of every mechanical contrivance hitherto devised, shortening of the limb is of frequent occurrence.

DR. PECK, of Iowa, offered the following resolution:

*Resolved*, That it is the opinion of this Section that shortening in cases of fracture of long bones is the rule in practice, regardless of any of the plans of treatment now in use."

A spirited discussion again followed the introduction of the above resolution, some strongly advocating its adoption, while others were equally strong in its opposition.

DR. HEVANS, of Missouri, did not think the passage of such a resolution advisable. He objected to any association voting upon a scientific subject.

DR. GUNN, of Chicago, thought it ought to be carried. He did not look upon the question as one of science, but one of fact. Shortening of a fracture was the rule, and full length the exception. This was the purport of the resolution, and he hoped it would be adopted.

The resolution was adopted, after which the Section adjourned to meet at 3 P.M., June 6, 1877.

SECOND DAY.—WEDNESDAY, JUNE 6TH.

The Section was called to order at 3 P.M. by the Chairman. A letter was read from DR. ROBERT BATTEY, of Georgia, announcing that he had been unable to complete his essay on "The Permeability of the Entire Alimentary Canal by Enema, and Some of its Surgical Applications," and asking that it be postponed to the next meeting. Permission was granted.

#### STRICTURE OF THE URETHRA FROM MASTURBATION, AND ITS PATHOLOGICAL SIGNIFICANCE.

In the absence of DR. S. W. GROSS, of Philadelphia, the author of the paper, it was read by PROF. S. D. GROSS. It contained the histories of a number of cases which had fallen under the author's observation, showing the ultimate result of the within-mentioned cause. In this connection Prof. Gross exhibited two new instruments to be used in the treatment of the stricture.

The paper was referred to the Committee on Publication.

#### MEDIO-BILATERAL LITHOTOMY.

DR. W. T. BRIGGS, of Tennessee, read a paper upon the above subject, which contained the following conclusions:

1. That the medio-bilateral is the simplest and safest, and, therefore, the best method of lithotomy. 2. That it is the method best adapted to a large majority of cases. 3. That it passes by the shortest and most direct route to the bladder. 4. That it lessens the chances of the surgeon's knife slipping out of the groove of the staff and passing into the space between the rectum and the bladder. 5. That by it tissues of the least importance are divided. 6. That if the median line be closely followed, and only a limited-section of the deep-seated parts be made, less blood is lost than by any other method.

The paper was discussed by DRs. HODGEN, LANGFORD, and GULEY.

DR. J. W. S. GULEY, of New York, took the ground that there was no best operation; that each case must be studied by itself, and that each case indicated by itself what operation was the best to be adopted.

With regard to perineal lithotomy.

DR. BRIGGS made an incision, and subsequently dilated the opening with the fingers.

DR. GULEY preferred to dilate by means of Dolbeau's dilator, to the extent recommended by Dolbeau, and then break up the stone. The Doctor also referred to the fact that the statistics proved the operation of

lithotomy to be much more successful than the operation of lithotomy; the rate of mortality in the first being only one in sixteen, while in the latter it reached one in eight.

DR. LEWIS A. SAYRE, of New York, then read a paper on

THE TREATMENT OF FRACTURED RIBS BY EXTENSION AND EXPANSION OF THE THORAX, AND RETENTION BY PLASTER-OF-PARIS BANDAGE.

With DR. SAYRE'S valuable suggestions regarding the use of the plaster jacket in the treatment of diseases of the spine the readers of THE RECORD have already been made familiar; another jacket for treatment of fracture of the ribs is to be applied in accordance with the same principles.

CONSERVATIVE SURGERY.

DR. QIMBY, of New Jersey, read a paper upon the above subject. A detailed account was given of a case in which one inch and a half of the tibia and fibula were removed, and a good limb given to the patient.

The paper gave rise to discussion, which was participated in by Drs. Hodgen, of Missouri, Truesdell, of Illinois, Blake, of Indiana, Link, Hughes, Myers, and others.

DR. LINK, of Indianapolis, maintained that bone could be reproduced independent of the periosteum.

DR. HODGEN, of Missouri, believed that inasmuch as the tibia and the tissues between it and the fibula were destroyed, the indication was for amputation, because of the danger of mortification, notwithstanding Dr. Quimby had made an excision, and saved the limb.

The papers read in the Section were all referred to the Committee on Publication.

The Section adjourned to meet at 3 P.M., June 7, 1877.

THIRD DAY.—THURSDAY, JUNE 7TH.

The Section was called to order at 3 P.M. by the Chairman.

SUSPENSION AS A MEANS OF TREATMENT IN SPINAL DISTORTIONS.

DR. BENJ. LEE, of Philadelphia, submitted a report upon the above subject, and in his absence it was partially read by Dr. Woodbury, who exhibited an appliance, designed by Dr. Lee, called a "Spinal Swing for Cases of Curvature."

DR. L. A. SAYRE, of New York, remarked that he regarded the apparatus as one of the most valuable which had been devised for the treatment of that class of cases.

DR. S. D. GROSS, of Philadelphia, then read a paper

ON THE IMMEDIATE OR PROXIMATE CAUSE OF PAIN.

DR. GROSS discussed his subject in connection with the following propositions:

*First.* That the nervous fluid, as it is called, is precisely similar to, if not positively identical with, the electric or galvanic fluid, modified of course by the play of the vital actions which everywhere exists in the organs and tissues through which the nervous fluid circulates. *Second.* That the fluid under consideration is generated by the brain, spinal cord, and nervous ganglia, and that the nerves are simply passive cords, ropes, or, so to speak, wires, for the transmission of the nervous fluid. *Third.* That what is called pain is

due immediately and directly to obstruction to the transmission of the nervous current, thereby causing an accumulation of nervous fluid at the seat of the obstruction. *Fourth.* That pain can take place only in connection with a sound state of the brain and spinal cord, or, in other words, that when these organs are seriously affected there can be no perception of pain or suffering whatever. *Fifth.* That pain is modified or influenced by structure, and by the nature of the exciting cause.

The paper was referred to the Committee on Publication.

DR. MARCY, of Cambridge, Mass., read a paper on

PLASTIC SPLINTS,

and exhibited a mill to be used in the preparation of the plaster bandages.

Referred to the Committee on Publication.

DR. SAYRE, of New York, presented a patient illustrating the lack of co-ordination and partial paralysis as the result of genital irritation. The patient was a girl twelve years of age.

RECENT ADVANCES IN OTOLOGY.

DR. S. D. JONES, of Chicago, submitted a paper on the above subject, an abstract of which was read by Dr. Andrews.

DR. JONES discussed the practical value arising from the anatomical divisions of the ear, and gave a description of instruments designed for the diagnosis and treatment of ear diseases. The most frequent seat of disease was the middle ear, in consequence of its immediate connection with the throat. Attention was drawn to the propriety of puncturing the drum under certain circumstances. The author believed that there were but few cases of catarrhal deafness which might not be relieved. It was difficult to conceive of such a thing as hereditary deafness. The Doctor then passed to the consideration of the management of deaf mutes, and alluded to the prospect of alleviating their condition by the sign-language, and, still better, by lip-reading. The paper was referred to the Committee on Publication.

OPEN-AIR TREATMENT OF WOUNDS

was the subject of a paper by DR. LINK, of Indianapolis. The author reported a very flattering result from this method of treatment. Referred to the Committee on Publication.

DR. LEWIS A. SAYRE, of New York, rose to a question of privilege, and entered his protest against the resolution adopted by the Section on Tuesday, to the effect that shortening followed fracture, in spite of any methods of treatment now in use. It was a confession, that the profession couldn't properly treat a fracture, and he protested against such a declaration.

DR. H. I. BOWDICH, of Boston, submitted a paper or

THE RELATIVE VALUE OF INCISIONS AND ASPIRATIONS IN THE TREATMENT OF EMPYEMA.

Referred to the Committee on Publication.

DR. FORSYTH described his *method of treating fractures*, and illustrated in the person of a young male patient.

VARICOSE ULCERS.

DR. MARTIN, of Massachusetts, spoke upon the above subject, and exhibited an india-rubber bandage which, in his hands, had worked a permanent cure in such cases, without any other adjuncts in the way of treatment. The Section then adjourned.

## SECTION ON MEDICAL JURISPRUDENCE, CHEMISTRY, AND PSYCHOLOGY.

DR. EUGENE GRISSOM, of North Carolina, Chairman.  
DR. E. A. HILDRETH, of West Virginia, Secretary.

FIRST DAY.—TUESDAY, JUNE 5TH.

## RELATIONS OF SPIRITUALISM TO MEDICAL JURISPRUDENCE.

DR. JOHN P. GRAY, of New York, read a paper upon the above subject, which consisted largely of a critical examination of the Ward will case. Dr. Gray arrived at the following conclusions:

1. Spiritualism must not be taken as evidence of insanity. 2. A belief in communications from the unseen world from supernatural messengers is not an insane delusion. 3. The belief that mediums can communicate with the dead is not an insane delusion, for no evidence has been as yet presented of the truth of such communications having been made. They are mere assertions of the so-called mediums. 4. The implication of fraud must stand against all such persons or communications, as the dead party cannot be reached except through the so-called medium, and therefore the living party to whom the communication is made has no power of communicating with the dead. The whole is received simply through the medium. 5. Such communications cannot be received in courts of law, as they are excluded by the rule of rejecting conversations not held in the presence of both parties. 6. If Spiritualism is espoused as the result of the disease of the brain, being before repugnant to the belief and mental operations of the individual, then it is an insane delusion. Spiritualism must be received simply, under such ruling of the court, as undue influence. When it is a fraudulent influence, or conspiracy in the case of writs or contracts, then the writs and contracts made under such influence must be void. 7. The most serious questions would arise where a person should attempt to commit homicide under the direction of the so-called spirits. The presence of a medium in such a case would suggest fraud and conspiracy. If the individual was a spiritualist through life and before the time, no insane delusion can be claimed unless it can be found in a brain disease. He would have to stand in that case upon the same platform as ordinary criminals. 8. Spiritualism can only be considered as an occasional delusion, and not as a cause or form of true aberration. It stands on the same footing as witchcraft, vampirism, &c. 9. The medico-legal bearing must be determined by the facts in such a case, whether it is an insane delusion or simply entertained as a speculative belief with reference to the unseen world in the possible condition of men after death. Medical science can take cognizance of it as a speculation more than it can of any other.

The paper was referred to the Committee on Publication.

DR. EDWARD SEGUIN, of New York, read a paper

## INTERVENTION OF PHYSICIANS IN EDUCATION.

This paper maintained that new progress in education could not be expected from any great discovery of the methods of teaching, but must come from an active intervention of the physicians in the training of children, which would act in two ways: First, by underscoring as much as possible the teaching in the open air, one means of doing which would be the creation of garden-schools, as proposed by Dr. E. Seguin.

The execution of this plan would relieve the schools from the contagious ferments generated by crowding, and would considerably diminish the chances of sickness and of mortality among children. At the same time the pupils would learn from Nature what they see imperfectly represented in books, and gain by this immediate contact a love of Nature and naturalness which would react on their future avocations. For these garden-schools would contain, not only classes of botany, natural history, etc., but classes of drawing, carving, and modelling from Nature, whence would issue generations of true artists and superior artisans.

But the second and most important part of the physician in education ought to be that of a keeper of the balance of the vital forces of the children. Each child must have his study-book where the account of his acquisition and expense of vitality should be kept. Physicians alone could register the idiosyncrasies of children, measure the difference of build and of capacity of both sides of the body and of all the double organizations, and recommend accordingly certain forms of active or passive exercises, etc. The accommodation of the ear and eye must be tested in order that each child occupy at school precisely the place, and use the printed types corresponding to his power of vision and audition. But, above all, the physician in charge of a school should register the movements of the great vital functions—the pulse, the respiration, and the temperature before and after various studies—in order to establish in figures the balance of what a child could spend in studying or could not, under the penalty of death from that too frequent disease, the scholar-meningitis.

The paper was referred to the Committee on Publication.

The Section then adjourned to meet at 3 P.M., June 6, 1877.

## SECOND DAY.—WEDNESDAY, JUNE 6TH.

The Section was called to order at 3 P.M. by the Chairman.

## DO FACTS JUSTIFY THE RECOGNITION OF MORAL INSANITY AS A DISTINCT FORM OF MENTAL DISEASE?

DR. R. J. PATTERSON, of Illinois, read a paper upon the above subject, in which he arrived at conclusions adverse to such recognition. His paper contained statistics from a large number of insane asylums running back over several years, and showing a very marked diminution of cases of so-called "moral insanity." This proved either that the disease was becoming less frequent, or that the doctors were losing their belief in the existence of such disease and attributed the cases to other diseases. Dr. Patterson objected to the recognition of moral insanity as a distinct form of mental disease, because there were no cases in which it was shown that a person suffered from "moral insanity," while the intellect was perfectly rational. No person would suffer by the denial of this recognition. The term, "moral insanity," not only did no good, but it did positive harm by enabling unscrupulous lawyers to set up a specious plea in behalf of their clients, especially in cases of homicide, in which there was no question as to the soundness of the intellect. The cases of Sickles, McFarland, and many others were cited here. And finally, very few of the highest authorities, medical or legal, recognized such a disease as moral insanity, and the plea of that disease was looked on with suspicion by experts.

DR. JOHN P. GRAY, of New York, remarked that the institution of which he had charge had been cited by Dr. Patterson as refusing to recognize moral insanity.

That was true so far as he was concerned, but his predecessor, Dr. Brigham, believed in it, and according to the asylum's records there had been two thousand cases of moral insanity in that asylum alone. Dr. Gray had examined ten thousand cases of insanity without finding one that he regarded as a case of moral insanity. Dr. Brigham made three or four classes of moral insanity. One class was the impulsive, that characterized by a single manifestation, such as an impulse to commit homicide, with no other deviation from health. Dr. Gray didn't believe such a case ever existed, but Dr. Brigham did. Dr. Gray would as soon think of impulsive diarrhea as of impulsive insanity. The idea of a disease that came in a moment and went in a moment conflicted with all his ideas of physiology and psychology. One of the asylums Dr. Patterson cited, that at Longwood, reported in one year a phenomenal amount of "moral insanity." Probably "rum" would express all of it.

Referring to the subject of heredity, Dr. Gray said that persons who suffered from moral taint, transmitted by parents, might be held to be morally defective, but it was unjust to them and the profession to regard them as diseased.

Dr. THOMPSON, of Mississippi, remarked that moral insanity was believed in more formerly than it is now, and Dr. Ray, the chief believer in moral insanity, had modified his statements in late editions of his own book.

Dr. BATTEY, of Georgia, said that in the asylums under his charge, where there were twelve hundred patients, there had been no case regarded as moral insanity in twenty-one years.

Dr. KNIGHT remarked that if the term "moral insanity" implied the perfect soundness of all the faculties except the moral faculties, there was no such thing.

In reformatories there were, he said, perfectly healthy boys who would rather do wrong than do right. Punishment they sought to evade, but if it is applied it does no good. They sleep well, and eat well, and their minds seem bright enough. It was doubtful if these persons were morally responsible.

Dr. EDWARD SECURIN, of New York, believed in moral insanity. In idiot asylums children were received who were worse than idiots. They had an inevitable habit, a necessary impulse, to sin. They had no symptoms of idiocy. They were healthy in body, and bright in mind. He told of a boy who had on twenty occasions shut himself up in a room and set fire to the furniture. He knew that he was doing wrong, but he had a necessary impulse to do it. That boy had been cured, and was a perfectly good boy.

The origin of moral insanity among children was a want, or better, a *besoin*. That boy had a *besoin* to see bright things as some people have *besoin* to speak constantly. His insanity was a sort of sensory insanity.

Dr. BUCK, of Canada, also believed in moral insanity. Two patients in his asylum were conspicuous examples of it. He had failed to detect in either any intellectual delusion, but their moral natures were so perverted that they couldn't live in society. One of these cases was a woman, who was clever, neat, intelligent, and in perfect health, but she was subject to violent attacks of passion, and had excessively erratic tendencies. The other was a man. His mind was sound enough, so that he had accumulated a fortune, and was perfectly healthy; but if at large would maltreat his family, and commit other acts, making his existence in society impossible. Dr. Buck believed there were many other cases in his asylum where the initial departure from health was in the emotional

nature. A very marked departure of the emotional involved the intellectual nature. He believed that a moderate moral aberration constituted criminality, while excessive aberration constituted moral insanity. The intellectual nature affected the emotional nature but slowly, while the emotional nature had immediate and tyrannical power over the intellectual nature.

The paper was referred to the Committee on Publication.

#### MEDICAL TESTIMONY, WITH SPECIAL REFERENCE TO CASES OF INSANITY.

Dr. G. R. BUCKHAM, of Michigan, read a paper upon the above subject, in which he set forth, in the first place, that physicians were not by education experts in such cases. Before graduation they were not required to study any particular branches in order to make them more "expert" than any other well-educated gentleman. Regarding cases of emotional insanity the Doctor did not believe that such a state of mind had ever been proved, and his natural inference was that there never was such a thing. A few changes were suggested by the writer in the medical college courses to remove the evils of which he had spoken.

Dr. YEAMANS, of Michigan, opened the discussion, which was continued by Dr. Bartlett, of Minnesota.

The paper was referred to the Committee on Publication, and the Section adjourned to meet at 3 P.M., June 7, 1877.

#### THIRD DAY.—THURSDAY, JUNE 7TH.

The Section was called to order at 3 P.M., by the the Chairman, Dr. Eugene Grissom.

Dr. BUCKHAM, of Michigan, presented a resolution, requesting the appointment of a committee to take into consideration the subject of medical testimony, and to report at the next annual meeting. The resolution was adopted, and the committee appointed consisted of Dr. J. P. Gray, Dr. E. A. Hildreth, and Dr. Knight. The following were appointed a committee to revise the papers read before the Section, and to transmit them to the Committee on Publication: Dr. D. F. Boughton, Dr. C. K. Bartlett, and Dr. D. R. Brower. The Section then adjourned.

#### SECTION ON STATE MEDICINE AND HYGIENE.

Dr. E. M. HUNT, of New Jersey, Chairman.  
Dr. D. R. WALLACE, of Texas, Secretary.

#### FIRST DAY.—TUESDAY, JUNE 5TH.

The Section was called to order at 3 P.M. by the Chairman, who made a brief statement regarding the work it was expected to perform.

In the absence of the Secretary, Dr. Williams, of Indiana, was elected Secretary *pro tem*.

Letters were read from Dr. Vandemann, of Tennessee; Dr. Catlin, of Connecticut; Dr. Smithecum, of Kansas, and from physicians residing in Colorado and New Jersey, in relation to the sanitary laws of those States.

#### THE ETIOLOGY OF ENTERIC FEVER.

Dr. J. L. CABELL read an elaborate paper upon the above subject, which consisted largely of answer from fifty-eight correspondents regarding the development of typhoid fever. Most of these letters attributed the origin of typhoid fever to filth, as is generally the case, but Dr. Cabell took up a number of cases where there was no end of filth, but typhoid fever was unknown. He believed that the laws affecting geru life were far from fully understood, an

that the facts did not warrant the *de novo* doctrine of Bastian's theory of heterogenesis. Speaking of the tenacity of germ life, he said Indian corn, a semi-tropical seed, had been exposed for years in the Arctic regions to a temperature seldom less than fifty degrees below zero, and yet it maintained its vitality. The replies he received indicated that typhoid fever was developed by excremental filth, by the use of milk from cans washed in tainted water, and by vegetable decomposition. Many correspondents cited much evidence to support the theory that decaying wood was far more likely to develop typhoid than was any other vegetable decomposition. A soil saturated with organic impurities was fruitful in producing typhoid. But Dr. Cabell said that typhoid was to be found where none of these causes were at work, and he regretted that the belief in excremental poisoning as the great source of the fever had caused physicians to overlook other hardly less important, but almost unknown causes. A large number of the replies cited many facts to show that there was an antagonism between typhoid and malarial fevers, and that typhoid is unknown where malarial fever is prevalent.

The paper was referred and the Section adjourned to meet at 3 P.M., June 6, 1877.

#### SECOND DAY.—WEDNESDAY, JUNE 6TH.

The Section was called to order at 3 P.M. by the Chairman.

The first paper was by DR. J. R. BLACK, of Ohio, on

#### THE LAWS OF HEREDITY, WITH SPECIAL REFERENCE TO THE TRANSMISSION OF MORBID TENDENCIES, ABNORMAL FORMS, AND THE EFFECTS OF INTERMARRIAGES,

of which the following is a brief abstract:

The improvement of domestic animals had long been deeply considered in all communities, and some, though weak, efforts had been made to improve the physical and mental condition of mankind. There was little wonder that the king of animals should be in his present degraded condition, for his physiological welfare had been practically neglected. Either man was exhausted by excessive work, or dwarfed by almost entire inaction. Even when some portions of the system were properly looked after and developed to a high standard, other portions were degraded by neglect or inaction, which often resulted in the deterioration of the whole system. Efforts were indeed being made to improve this state of affairs. Children were fed with plainer food and made to take more exercise. The evil of hereditary taints and the evil of intermarriage were not acknowledged, or at least not heeded. In Connecticut and Rhode Island the evil of intermarriage among relations was so great that the people were gradually dying out, and the birth rate among this class was growing less year after year. The result was, and the same course of action would only make it more so, that now nearly one-half of the population of such communities was spent in looking after the other half. In such communities the cases of inherited diseases of many kinds were fearfully numerous, and the cases where persons were entirely free from inherited diseases were very few; but few of such could be found who were entirely free of diseases inherited from parents. The speaker then referred to the statistics of hereditary diseases, and the various types of them. In mentioning the number of those afflicted with hereditary diseases, he stated that among ninety-three physicians and their wives, of whom reports had been presented, only fifteen males and eighteen females were reported as entirely free from an inherited predisposition to disease. A care-

ful study had shown that there was no differential law of descent in reference to the sexes of those who were suffering from inherited disease, or of the tendency to the limitation of a defect to the sex in which it originally appeared.

The reader of the paper then spoke of the curious fact that among the Jews, where full statistics had been taken, there was greater longevity than among the Germans, among whom they lived; that the average life of the former was eleven years longer than that of the latter. In describing special cases he described numerous interesting cases, in one of which the child, when in bed, moved its big toe about in the same way in which its mother had done. Like things begot like things, and the capriciousness that sometimes appeared, or which was thought to appear, was only apparent; it was not real.

From the statistics which the Doctor had been able to collect, the conclusion was reached regarding

#### CONSANGUINEOUS MARRIAGES

that the chances of the issue having well-formed bodies and sound minds were so small that the strongest legal enactments against them were justified.

In conclusion, the lecturer declared that the more the primitive phases of civilization were considered the more apparent did the fact become that the somewhat violent hardships and privations to which life was then exposed fell with special force on the weak and helpless, and little, if at all on the vigorous, thus tending to the elimination of the one and the perpetuation of the other. It was apparent, further, that few persons possessed the strength of mind necessary to abstain from the perpetuation of the species, simply because they inherited a congenital disorder. Yet even this fact had an outcome not to be deplored. High intelligence, strong wills, and consistent behavior would survive, while feeble-minded ignorance and volitions unstable as water would carry the blood on to imperfection, disease, and extinction.

Discussion was participated in by Drs. Bell, of New York, Pratt and Lester, of Michigan, and others. Some of the speakers concurred in the opinion put forward by the essayist, while others thought his strictures relative to marriages between blood relatives were too severe.

The paper was referred to the Committee on Publication.

#### TUBERCULOSIS IN MILCH COWS AND THE CONTAGIOUSNESS OF TUBERCULOSIS BY THE DIGESTIVE ORGANS.

DR. A. N. BELL, of Brooklyn, read an elaborate paper upon the above subject, in which he spoke first of its nature, and then of the contagiousness of tuberculosis by the digestive organs. In considering the latter part of the subject he spoke at length of the danger of imbibing tubercular consumption through milch cows, by the use of milk from the cows infected with the disease. The fact that tuberculosis was transmissible was an undoubted one.

The aim of Dr. Bell's paper was to point out the unerring certainty of death to animals fed upon animal tissues infected with tubercular deposits. A large number of experiments upon horses, dogs, cats, and cows were cited from French, German, and Italian veterinary pathologists in the prosecution of their researches upon the contagiousness of tubercle through the medium of tubercular meats. The results of these experiments pointed to the certain transmissibility of tubercle. The deductions from the paper were, that the strictest police inspection of public meat markets should be instituted, and tubercular meats unhesitatingly thrown away, and heavy fines and

severe punishments should follow the sale of prohibited articles.

Dr. BELL's paper was referred to the Committee on Publication, with the provision that it might be taken up for discussion at a future meeting.

Dr. COMEGYS, of Cincinnati, read a brief paper on

#### STATE MEDICINE,

in which he contended for a more rigid enforcement of the laws in regard to the practice of medicine. Unqualified persons should not be allowed to practice, and the State should exercise a careful supervision over the issuance of diplomas. Another point was, that the medical profession was practically excluded from political life. The author concluded by offering the following resolutions, which he respectfully submitted for the consideration of the Committee on State Medicine:

"Resolved, That the medical profession, by reason of its paramount claims as guardian in so great a degree of the best interests of society, should seek to give authority to its claim by making the State the expression of it.

"Resolved, That it is the duty of the medical profession to labor for the establishment of a Medical Council of State in each State, which shall be empowered by law to make rules and regulations for the qualifications of medical practitioners and the regulation of whatever is connected with public hygiene.

"Resolved, That it is the duty of the profession to exert its influence to secure a fair representation of physicians in legislative bodies, because their participation in legislation is most important to the public weal.

"Resolved, That the devotion of physicians to medical politics will not hinder their culture or usefulness as practitioners, but rather will greatly strengthen them in their ability to promote good order and human happiness."

The Section adjourned without adopting the paper or the resolutions offered by Dr. Comegys.

#### THIRD DAY.—THURSDAY, JUNE 7TH.

The Section was called to order at 3 P.M. by the Chairman.

#### THE RESULTS OF LEGISLATION ON PUBLIC HEALTH

was the title of a paper read by

Dr. ELISHA HARRIS, of New York. The substance of the paper was as follows: The public health laws have been enacted in most instances without the aid or preparatory conference of such medical and judicial experts as could alone give the most suitable directions and definitions to the statutes, and until certain State medical societies and capable experts in hygiene were consulted not one of the States succeeded in enacting the essential and practical provisions which were most necessary in this class of laws. In nearly every State the legislation on public health matters had been obtained too easily, and at the suggestion of persons who could not probably give the precise form and adaptation which both the construction of the statute and definition of methods or powers of their administration required. The general statute by which the powers of local authorities were defined, and by which the specific acts most needed for sanitary protection were enjoined, utterly failed to set in motion any methods or individuals competent to discharge the duties to which the more or less elaborate provisions of the enactments related. A statute had for the past fifteen years provided that the common school officers should require every pupil who attended school to be vaccinated or exhibit proofs of vaccination, and

the same law required the school board to appoint vaccinating physicians and to pay as other employed persons in the school were paid. That law, of course, was a dead letter. That instance of useless sanitary law-making might suffice for illustrating the point just stated. It might be quoted as an illustration of short-sighted methods of attempting to attain great and good results. The object and even a part of the methods were worthy and right, but the sanitary duty itself was not set in motion by competent authority and skill, and, indeed, there was but the remotest probability that the most essential parts of the requisite sanitary work would be set in motion at all. It might be supposed that the laws for preventing or abating nuisances, draining, sewerage, regulating the sanitary wants of lodging-houses, etc., would be well enough administered by common authorities of police or supervisory inspection, yet experience had abundantly proved that there was great need of a central intelligence and responsibility for the plans. There was a certain large township in the State of New York in which for forty years past the entire resident population had enjoyed an immunity from small-pox, such as had perhaps never been experienced in any American town. Yet no law of the State had been invoked to produce this result. One noble physician had maintained the Jennerian faith and practice, and had with equal ease secured the complete isolation of every case of small-pox which had appeared in that time, whether it were a passing traveller or a family or family servant. The authority of the laws had not been exercised, but the opinion and decisions of one had superseded the appeals to law. The public health laws in each State have been devised with the intention to provide for—

1. The organization of local boards of health.
2. The definition of the powers and duties assigned to them.
3. The definition of nuisances against health.
4. The specific provisions against contagious diseases.
5. The isolation or quarantining of the alleged communicable causes of contagious and pestilential diseases.
6. The regulation of certain sources of contamination of foods and beverages.
7. The removal and prevention of several sources of disease and danger in communities, for the reason that life and health should be protected.

The specific provisions against contagious diseases, namely isolation, destruction of property, and the establishment of a rigid quarantine, were too often abused. A conference between the medical, political, army and navy authorities would be a basis for action.

The paper was referred to the Committee on Publication.

Dr. HUNT called Dr. COMEGYS to the chair.

Dr. SUTTON, of Indiana, presented a paper

#### ON TRICHINA SPIRALIS,

in which he advocated the passage of an act forbidding swine to run at large, or to be fed by the refuse from distilleries.

The paper was discussed by Drs. HARRIS, of New York, and OHR, of Maryland.

There being no further business the Section adjourned.

THE SUMMER VACATION.—With the present month all the medical societies in this city will adjourn until their regular times for meeting in September. In the mean time we hope to have the opportunity of finding room for the unusual amount of Society material which has been accumulating during the past few weeks.

## Reports of Societies.

### MASSACHUSETTS MEDICAL SOCIETY.

*Stated Annual Meeting, at Boston, Mass., June 12th and 13th.*

(Special Report for THE MEDICAL RECORD.)

FIRST DAY.—TUESDAY, JUNE 12TH.

The Annual Meeting of the Massachusetts Medical Society was held in the hall of the Lowell Institute, Boston, on Tuesday and Wednesday, June 12th and 13th.

The meeting was called to order at noon, on Tuesday, by the President, DR. COGSWELL, and the reading of scientific papers was begun.

#### ERYSIPELAS AND PUERPERAL FEVER.

The first paper presented was on Erysipelas and Puerperal Fever, by JOHN M. CROCKER, M.D., of Provincetown. The reader reported his experience in attendance on the practice of midwifery during an epidemic of erysipelas. Although he attended several cases of midwifery during that period, no cases of puerperal fever occurred. The same was true during an epidemic of scarlet fever. The reader held that the poisons of erysipelas and puerperal fever were not identical, and that where epidemics of both diseases coexist there is some connecting link, some essential element, which it is our duty to endeavor to discover, though it may be very difficult to find it out.

#### DIPHTHERIA.

A paper on Diphtheria was next read by DR. J. H. GILMAN, of Lowell. The reader held to the opinion that the malady is, *ab initio*, a local disease, and that the system becomes infected from the absorption of putrescent material from the throat. Hence, in his opinion, the necessity of attendance on the case from the very outset, and of the endeavor to prevent the infection of the system by the application of remedies to the fauces.

#### ALCOHOL.

DR. W. W. EATON, of Danvers, read a paper on Alcohol: Its Use and Abuse in Disease. He believed that irreparable damage was often done by excessive stimulation in acute disease. Alcohol he regarded as a poison, to be as carefully prescribed as is any other poisonous remedy. He denied that it was in any sense a food, but acknowledged that it may at times be beneficial in critical states of acute disease, in anemia and cardiac weakness.

Cell Emigration and its Relation to Inflammatory Processes was the subject of a paper by DR. G. M. GARLAND, of Boston. The reader gave a succinct account of the views of the leading German pathologists, as at present held by them.

#### INTRA-UTERINE INJECTIONS IN POST-PARTUM HEMORRHAGES.

S. W. TORREY, M.D., of Beverly, read a communication on Intra-uterine Injections in Post-partum Hemorrhage. He mentioned particularly the use of solutions of the persalts of iron, and the dangers attendant thereupon. The hæmostatic property of the iron solutions he regarded as due to their constringing and not to their coagulating power. In the latter resides their source of danger. A material that will constringe and not coagulate will be likely to cause much

less danger to the patient. The reader stated that Churchill's tincture of iodine was such a remedy, and that it had been successfully employed in New York and elsewhere for the purpose of controlling uterine hemorrhage.

#### BOLLES'S SPLINT FOR COLLES'S FRACTURE.

DR. W. P. BOLLES, of Dorchester, showed many forms of splints as used by different surgeons for the treatment of Colles's fracture, and also one of his own invention, carefully carved to fit the somewhat spiral curve of the forearm. He had obtained good results from the employment of his splint in several cases of the lesion under discussion, and he exhibited several patients with the splints applied.

#### SKIN GRAFTING.

W. SYMINGTON BROWN, M.D., of Stoneham, reported a Case of Skin Grafting, and showed the patient, a young woman, who, nearly five years ago, had her entire scalp torn off by her hair being caught in a revolving belt. Although the scalp was immediately replaced, it subsequently shrivelled up, and had to be cut away. During three years subsequent to May, 1873, 2,600 grafts of skin were made upon the patient's head, and now the entire scalp, with the exception of a small space over the left eye, has been healed. The eyelids have thus far remained unhealed, but it is hoped that a plastic operation may be performed upon them after the summer season has passed.

#### SECOND DAY.—WEDNESDAY, JUNE 13TH.

After the reading of this paper, the Society adjourned, and reassembled at 9 o'clock on Wednesday, when, after the reading of the records and the reports of committees, the reading of medical papers was resumed.

Written reports of cases of interest and of epidemics were received from several district societies, after hearing portions of which, a paper by H. W. DUDLEY, M.D., of Abington, was read, on Endometritis and its Treatment by Scarification. Dr. Dudley mentioned the advocacy of the method of treatment by Dr. E. D. Miller, a Fellow of the Society, in a paper published by Dr. Miller in 1867. When the treatment by scarification is indicated it should often be boldly done: sometimes two or three ounces of blood being withdrawn at one time.

#### MISCELLANEOUS SUBJECTS.

The value of medical opinions was the subject of a paper by DR. G. S. STEBBINS, of Springfield. The reader discussed many of the questions which interest the profession and the public, such as public hygiene, State boards of health, medical education, medicolegal questions, legislation in behalf of legitimate medicine, the proper remuneration to the physician for his attendance on his patients, etc., and closed with commendatory remarks of the recent efforts on the part of the Medical Department of Howard University to establish a higher grade of medical education.

DR. GEORGE JEWETT, of Fitchburg, read a paper on Surgical Injuries of the Head. He based his paper on the history and results of several cases of severe injuries of the head, which had occurred in his practice. He urgently enforced the necessity of early operation in cases of compression of the brain due to effusion of blood between the dura mater and the skull, to let out the effused blood before inflammatory symptoms set in, and convulsions, stupor, and hemiplegia arise.

A paper, on a Disease Peculiar to Young Men, was

read by Dr. G. W. DOANE, of Hyannis. Such cases were often spoken of as due to self-abuse, but the reader knew of many who were the subjects of frequent and troublesome seminal emissions who were not guilty of any immoral practices. They were youths and young men from the best families, brought up to shun vice; but they were very likely to become depressed in mind, and many of them developed insanity later in life. The only cure he could recommend was marriage, and in many cases he had found it efficacious.

Delegates from other State Medical Societies were introduced by the President: Drs. Jenkins, Farnham, and Chase, from New York, Dr. Chamberlain, from Connecticut, and Dr. Eastman, from New Hampshire. Drs. Jenkins and Chamberlain made brief addresses.

#### ANNUAL DISCOURSE, ETC.

At twelve o'clock the Annual Discourse was delivered by Dr. JOHN R. BRONSON, of Attleboro, entitled, *A Review of Medicine: Its Work and its Worth*. After giving a sketch of the progress of medicine from antiquity to modern times, the orator stated that American colonial medicine had its birth at a period when European medicine was being agitated by rival pathologists. Laboring under great embarrassments, in a foreign land and an inhospitable climate, isolated from all the world, it is a wonder that it survived. A period of great depression ensued. But, immediately succeeding our independence, the old medical schools were reorganized and new ones established. During the last quarter of a century the rapid advancement of medicine is largely indebted to scientific specialists. The speaker forcibly urged the necessity of careful, persistent clinical study by the student of medicine, if he would attain a thorough medical education. Clinical medicine can only be advantageously studied in our larger cities. The practical application of this view would necessitate the closing of our country schools, and should do so at once. The speaker regretted that hygiene and preventive medicine had received so little attention from the profession in this country. But little thought has been given to what may be denominated medical politics. The medical profession should address itself to the suppression of quackery; to the bringing to justice criminal abortionists; to the suppression of the sale of quack medicines. It should use its influence to have proper regulations enforced regarding the attendance of children at school, and also regarding their course of study.

The orator further, in a somewhat guarded way, advocated the admission of females to the State Medical Society. He spoke in terms of approval of the efforts of the Society to rid itself of those who violated the spirit and letter of its by-laws, and after denouncing the various pathies and dogmas which legitimate medicine condemns, he assured his audience that our duties to the public having been performed, we have no fears for the medicine to come. The oration ended with a feeling tribute to the honored dead.

At one o'clock p.m., the Society passed to the Music Hall, where nearly six hundred Fellows engaged in the exercises of the Anniversary Dinner. Among the invited guests were Professors Austin Flint and J. C. Dalton, of New York, the former of whom in reply to the toast, "Our Honorary Members," expressed the satisfaction he felt in having during the past year been made an honorary member of the Society, of which at the beginning of his professional life he was an active Fellow.

At the Councillor's meeting on Tuesday evening the following were elected officers of the Society for the ensuing year:

President, Dr. William Cogswell, of Bradford; Vice-President, Dr. Gilman Kimball, of Lowell; Treasurer, Dr. F. W. Draper, of Boston; Corresponding Secretary, Dr. C. W. Swan, of Boston; Recording Secretary, Dr. F. W. Goss, of Roxbury; Librarian, Dr. D. H. Hayden, of Boston; Orator for the next Annual Meeting, Dr. Francis Minot, of Boston; Anniversary Chairman, Dr. Peter Pinceo, of Hyannis.

The next Annual Meeting will be held in Boston, on the second Wednesday in June, 1878.

## Progress of Medical Science.

ON THE TEMPORARY PRESENCE IN THE HUMAN BLOOD OF A LARGE NUMBER OF VERY MINUTE RED GLOBULES.—Drs. Lépine and Germont, of Paris, report that in examining the blood of a patient suffering from carcinoma of the stomach they were surprised to find a large number of minute pale red globules, two to three thousandths of a millimetre in diameter, and in number about equal to that of the red globules. The little bodies had the contour of microcytes; that is, they were spherical or nearly so, and not bi-concave. Their color was less pronounced than that of the ordinary red globules, so that it required close scrutiny to distinguish them from the little white corpuscles. The blood was obtained in the usual way, that is, by puncture of the finger; it was then deposited upon a glass slide and covered, without the addition of any reagent. Two days later, when the examination was repeated, there was not a single one of the red spherules to be seen, nor could any afterwards be found. In a second case of carcinoma of the stomach, in a patient aged forty-six, an examination of the blood showed that there were vast numbers of the minute red globules which did not have a diameter of quite five thousandths of a millimetre, and equalled in number the red blood corpuscles, while there was a goodly number of red corpuscles from two and four thousandths of a millimetre, at the extreme limit. Subsequently there were rouleaux of red globules, the smallest having a diameter of five thousandths of a millimetre. There was no notable change in the general symptoms between the two examinations to account for the change in the blood. In this connection reference is made to an article on the same subject by Litten, in the *Berl Klin. Woch.*, No. 1, 1877, where this temporary microcythemia was noticed in the blood of a man of twenty, who had œdema of the lungs, and also in three anæmic persons, a point which other authors have noticed. In two of these latter cases there was a remarkable change in form of the red globules. To account for such temporary appearances two hypotheses are presented: one that they are the new formation of a great number of red globules, which are in the process of development into the large globules; or, that they result from fragmentation of the large red blood globules. The author adheres to the former theory, though as yet it lacks a sufficient amount of evidence in its favor.—*Gazette Méd. d Paris*, May 5th, 1877.

A CASE OF TRAUMATIC TETANUS TREATED BY WHISKEY.—Dr. Ezra Reed, of Terre Haute, Indiana, contributes a new case of recovery from this terrible disease. Michael N., while at work in one of the machine-shops at St. Louis, was struck by a fragment of railroad iron, which tore the muscular tissue between thumb and forefinger. The laceration was slight, an

in six days the wound was healed. Fifteen days after the accident he had tetanic spasms and a stiffened jaw. When seen by Dr. Read he was lying upon the back with a ghastly expression of the countenance, his jaws were firmly fixed, and all the cervical muscles were rigid and hard. The hands were folded across the breast and immovable. The pulse was 112, and small; surface cool and moist; there was absence of pain, but the spasms came on at intervals of from 20 to 40 minutes. He was particularly sensitive to noise and touch, which invariably produced spasms. These symptoms gradually increased for three days, the pulse, only, remaining about the same. From this period the symptoms were remarkably uniform for thirty days, when resolution set in. During this time the sardonic grin, with retracted cheeks, and forehead drawn into furrows, eyes distorted and fixed, and nose drawn up, were permanent characteristics of the case. The treatment consisted in the giving of three-grain doses of calomel daily for five days, with twenty grains of quinine in five-grain doses, the object being rather to combat malarious influences than the disease in question. Hydrate of chloral was given for three days, and the frequency of the spasms was thereby lessened, but cumulative action being feared it was suspended for whiskey, of which he drank three gallons a week, or a little more than three pints daily. To the whiskey the doctor attributes the cure, and states that though really drunk from day to day, he was happy. During this time the food consisted of animal broths, beef and corn-meal gruel. This is the first case in Dr. Read's experience in which he has seen tetanus cured, and he thinks that so long as his good sister State Kentucky continues to manufacture copper-distilled whiskey, he shall not pronounce tetanus a mortal disease.—*Chicago Medical Journal and Examiner*, May, 1877.

**MECHANISM OF THE HIP-JOINT, WITH SOME DIAGNOSTIC POINTS UPON DISLOCATION AND FRACTURE OF THE NECK OF THE FEMUR.**—In a paper read before the Philadelphia County Medical Society, on February 28th, Dr. Allis stated that the hip-joint is the only true enarthrodial articulation in the body. The head of the bone is more than half received into its socket, and is retained therein by atmospheric pressure. Neither the ligaments nor the muscles, according to him, contribute to this retention. It is maintained by the cartilaginous rim about the socket, which is called by some anatomists the sucker ligament. If the joints were held in place by the ligaments, any of the ordinary movements of the limb would be suddenly arrested, as soon as a ligament would become tense; if by the muscles, displacements would constantly take place in paralysis, anaesthesia, sleep, etc. The capsular ligament being thin and loosely attached posteriorly, offers no impediment to the movements of the bone; anteriorly it is thick and strong, and is strengthened by accessory fibres, and by the tendons of the psoas, iliacus, and rectus muscles which are banded with it. Hence it is that man is enabled to stand erect, for without this special support the head of the bone would leap from the socket at every step. Standing erect is a muscular act and hard work; in standing at rest, soldiers balance the weight of the body on one leg, the body being thrown a little forward and outward. In this position the strain is taken from the muscles and placed on two, or possibly three ligaments—the teres, the ilio-femoral, and ilio-tibial, a trip of the fascia lata. The ligamentum teres only approaches a tense condition when the limb is in a state of adduction, and moreover, Henle has observed that adduction is possible to a much greater degree,

after the capsular ligament has been cut away. Hence, it is highly probable that this ligament does not contribute to the strength or security of the joint, but is simply the protector of the nutritive supply to the head of the femur.

The anterior portion of the capsular ligament forms a cup for the head of the bone and fixes it securely when in the resting posture. The structure, however, which contributes most largely to the *standing at rest* attitude, is the thick, strong portion of the fascia lata extending from the crest of the ilium to the outer side of the head of the tibia. It is attached to the linea aspera along its whole length. When we stand erect, this may be felt as a round cord about an inch from the outer side of the patella on each side. When the weight is thrown on one leg, this cord becomes more prominent on that side, and disappears on the other, and vice versa.

In making a diagnosis of injuries of the hip, it is important, when possible, to make the patient assume the upright position. In this position:

1. In fracture (complete) of the neck, there will be no marked deformity, no want of parallelism between the limbs, and both feet can be brought flatly upon the floor. In all cases of dislocation, the femur will have a fixed position; the knee can never be brought into a similar position with its fellow, and the foot can never be placed flatly upon the floor.

2. In fracture within or partly without the capsule, the limb, when in the erect position, is suspended by ligaments and muscles, and by the mere force of gravity hangs by the side of its fellow. In dislocation, the head of the bone lies in an abnormal, constrained position. The deformity will be greatest when the rent in the capsule and laceration of the muscles and tendons are least.

3. In fracture of the neck, the patient can rotate the limb almost as completely as in health, because the insertions of the rotator muscles are undisturbed, the capsule is intact, and no impediment is placed upon the free motion of the limb. In dislocations, on the contrary, the hip is always fixed.

4. In fracture of the neck, there is no longer the firm union between the limb and the trunk that is to be found in the sound limb. The thigh can be bent backward to a greater extent than its fellow. In cases of this injury, Dr. Cleeman has noticed a little wrinkle or fold in the tendo-patellæ due to shortening. When extension is perfect and the limb made equal to its fellow, this wrinkle is smoothed out. In fracture of the neck, the tension of the fascia lata and the ilio-tibial ligament is diminished.

In regard to measurements, it is necessary, in order to guard against error, to measure from several points, as the anterior superior spine of the ilium, the symphysis pubis, the point of the coccyx, etc. The degree of shortening in dislocations will depend largely on the condition of the ilio-femoral ligament. When this is untorn, the head of the bone must lie in close proximity to the socket, and the shortening will be slight. When there is doubt whether the head of the bone has returned to its socket, the limbs may be compared while at right angles to the trunk. If both are in their sockets, their length will be the same. This position may be utilized in the diagnosis of fracture from dorsal dislocation; in the former, the foot can be raised to the level of its fellow, but will shrink one-half to three-fourths of an inch when let go. In dislocation the shortening will be greater, will not disappear till the head of the bone is returned to the socket, and then will not reappear on removing the support.—*Medical and Surgical Reporter*, April 7th, 1877.

# THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, June 23, 1877.

## SHORTENING IN FRACTURES.

THE adoption of the resolution by the Surgical Section of the American Medical Association at its last meeting, regarding shortening in fractures, has a more important significance than would at first appear. The necessity for the deliberate declaration on the part of the surgeons present that shortening in fractures of long bones was a rule rather than exception seems to have been occasioned by some erroneous impressions to the contrary, which were created by a paper on the subject before the same body three years ago. It will be remembered that, at the time, there was a considerable discussion upon the subject, and that Dr. Sayre, the author of the paper, was called upon to defend his views against the majority of his surgical brethren. Contrary to his intention, the impression was nevertheless conveyed that not to secure union of the femur, for instance, without shortening, showed lack of skill. So far as the matter may be one of mere opinion, it would be safe enough to leave it, as each surgeon would be able to draw his own conclusions, based upon his individual study, observation, or experience. But such an opinion extends beyond the pale of strictly professional influences, and from a medico-legal point of view has an importance which can scarcely be overrated. It is obviously unfair to commit the profession to a point concerning which there has been and still is a great deal of doubt. With the view of placing the question in its proper light before the legal profession, and affording the surgeon who may be sued for malpractice a proper defence, the Section has placed its verdict on record. In any case of trial for malpractice in the treatment of fractures it would be safe to leave the question of culpability to a jury of experts; but when it must be settled by laymen influenced by the special pleading of the plaintiff's attorney, the result may be hazardous.

We are not prepared to believe that a fracture of

the femur, even in an adult, may not unite without shortening, but we feel warranted in saying that when such a circumstance occurs it is of importance on account of its rarity. A great many cases have been reported proving the contrary, but such proofs have been far from absolute. The chances for discrepancies in measurement are very great, even with the best and most experienced surgeons. We have seen a case of fracture of the thigh measured in which there were variations in the measurements by experts from nothing to almost half an inch. The late Dr. Buck, who had given a great deal of attention to the subject, used to tell the story of a student of his, who, after having been informed by an eminent surgeon in one of the London hospitals that there was no shortening in a case of fracture of the femur, quietly and carefully measured the same, to find that there was a difference of three-quarters of an inch. At that time it was the custom merely to place the internal malleoli together and note the result. Fallacious as this system of measurement may have been, our present methods in reference to deciding the really fine differences are no better. Measurement, to be strictly accurate, must be mathematical. That the latter can never be attained in the measurement of any of the long bones is plain to every surgeon. Even if the shortening is to be expressed by the term apparent, there is a wide latitude for the expression of the degree.

It is perfectly proper that every surgeon who may be sued for a shortened limb should have the benefit of a doubt, but the latter can never be given him if the standard of excellence in treatment is assumed to be absolute equality in the length of corresponding limbs. While it is acknowledged that every surgeon should not rest content until this standard is reached, he nevertheless should not be held to account for the usual failures. From a medico-legal point of view, then, it is quite important that a protest should be made against the impression created by the paper in question.

## MEDICAL COLLEGE ASSOCIATION.

A LARGE number of representative medical colleges in this country have formed themselves into a confederation for the purpose of advancing the interests of medical education. From present appearances the members seem to be in earnest in their efforts at reforming many of the existing abuses. As so much depends upon the actions of the colleges themselves in improving medical education and advancing the standard of scholarship, this movement deserves encouragement. The regulations which have been adopted are excellent, and if obeyed by the members will have a powerful influence in bringing about the understanding which has heretofore been so necessary to promote the interests of all. The promise is given the profession that every effort will be made to educate candidates thoroughly, and that no disposition

to graduate improper persons will be tolerated. So may it be.

#### MEDICAL EDUCATION IN VERMONT.

WE are pleased to see that the Vermont Medical Society has passed resolutions deprecating the lamentable deficiency in the preliminary education of candidates for diplomas, and that it requires of every student a good academic education, a certificate signed by a majority of the Board of Censors, or a diploma from some accredited school or college. A list of questions is to be published and used in the examination of students desiring to study medicine, and the answers must be approved by a majority of the Board before the applicant can be received. This is a step in the right direction, and it is to be hoped that the Society will have the power and the disposition to enforce the necessary obedience to the regulations. If we are to judge from the experience in this matter in our own State, we are not very sanguine of improvement. But we are willing to await the issue.

#### MORAL INSANITY.

THE remarks on Moral Insanity, before the Section on Psychology, are quite interesting as proving the great difference of opinions, even among experts, concerning the nature and significance of this so-called disease. On the one hand, a gentleman of great experience states that he has never seen a case, while others believe to the contrary. In any event, it would seem that the whole subject requires to be studied anew without delay, else there is no telling how many criminals may be punished.

## Correspondence.

### A REPLY TO DR. KNAPP ON OPHTHALMOSCOPE-MAKING.

[TO THE EDITOR OF THE MEDICAL RECORD.]

DR.—As Dr. Knapp has addressed some questions to me through the columns of your last issue, would you kindly allow me to answer them, although they are foreign to the point at issue?

The first question is: "If he (Dr. Loring) thinks all glasses are optically not so good, why did he adopt them?" I adopted the small glasses in 1869, four years previous to Dr. Knapp, because I thought at the smaller the space into which we could get a given number of glasses the better. I gave them up principally because, as stated in my paper, the expense that time was so great for accurate optical work as actually to exclude their use; as a secondary reason, because I did not think them optically so good, nor at the present moment, as is shown by the fact that I never have used personally an instrument in which the glasses are less than six millimetres. When these small glasses came again into vogue I was induced to return to them principally through the presentations of Wecker, in Paris, by whom, it was

shown in my last paper, their use was first suggested to Dr. Knapp. The objection to them was, as I employed them first, that when they are of the same size, or within a trifle of it, as the hole in the mirror, a continuous canal is formed of mirror and disk, and a very troublesome reflex is formed from the unpolished edges of the glasses (that is, the ground glass border), and projects into the aperture of the mirror. This reflex was avoided in my instrument as made lately, by a very delicate flange around the circumference of the glass. I always supposed it was to render the instrument more perfect optically, and from the objections which I have raised from time to time against the smaller glasses, that Dr. Knapp has latterly increased the diameter of his glasses twenty per cent. My return to the use of these glasses was cited simply to show that I did not take them from Dr. Knapp. I cannot, moreover, understand what "problem" has been solved by Dr. Knapp in regard to the size of the mirror hole, the identical dimensions of which have been in common use for twenty years or more, not only by me, but by others.

The second question is: "If he (Dr. Loring) discarded the spring for centering the glasses in order to avoid reflections, why did he take it up again later?" Because, with a return to the smaller glasses, I became convinced it was of service in stopping the small glasses precisely opposite the hole in the diaphragm, the reflections having been already removed by the flange alluded to. The fact that Dr. Strawbridge, of Philadelphia, and Dr. Oldham, of London, had used this spring for centering the glasses long before Dr. Knapp had produced any instrument whatever, was cited simply to show that I did not take the idea from him. Even in his last paper Dr. Knapp entirely ignores these previous labors, though the citation where he can find them is given, and he talks seemingly with the desire of impressing those unacquainted with the facts of his originality in this matter. As a matter of fact, the model which I showed before the Academy of Medicine before Dr. Knapp's single-disk instrument appeared, had this spring attached to it.

Third question: "If he (Dr. Loring) personally prefers to have the posterior surface of the glasses exposed to get rid of a source of annoying reflections, why did he cover them?" So far as I personally am concerned, which is all I stated, I did not cover them, as I use to this day an instrument in which the posterior surface of the glass is exposed. As it was considered by some an advantage to have the posterior surface of the glass covered, I improved, I thought materially, the various covers then in existence.

Fourth question: "And why did Dr. Loring adopt all these arrangements only after he had found out that my single-disk ophthalmoscope was favorably received?" I adopted all these arrangements and improved on them for the same reason that Dr. Knapp adopted them from others, as shown in my last paper. I could see no reason, when so much had been adopted from me, why I in turn should not improve on what others had done, and this I intend to do, always endeavoring to acknowledge the true source from which I take my ideas. Moreover, I adopted them before, and not after, I knew of the favorable reception of what Dr. Knapp calls his instrument. Dr. Knapp's concluding sentence is as follows: "Truly so long as he (Dr. Loring) does not prove that his single-disk ophthalmoscope with twenty-four glasses was made before mine, I have nothing to take back of what I have written or may have said."

Does the fact that my last modification, with all its improvements (the acknowledged result of many

workers in many fields)—does the fact that this appeared after Dr. Knapp's prove that I took all the fundamental principles from him? On the contrary, it remains with Dr. Knapp to show that the printed evidence I have produced that he took the fundamental principles from my earlier instruments to form his, is not correct.

As the matter stands now, it is as follows: It is not denied by Dr. Knapp that he publicly accused me of taking from him all the important parts of my ophthalmoscope. In my paper, which was an answer to these statements, it was not only shown, by a long citation of facts, dates, and references, that I had not taken the essential elements of my instrument from him, but it was also shown from just what sources, including myself, he had taken what he was pleased to dwell upon as a *new* ophthalmoscope. Not one of these facts were controverted. Moreover, the fact remains that when it was proved in my paper that what he said to his class "was not in accordance with the facts," he did not deny the assertion or seek to substantiate the truth of his remarks by the citation of a single authenticated fact.

In contrast with what Dr. Knapp has declared to his students, may I be permitted to cite what the Professor of Ophthalmology of the University has stated to his class: "After all, the fact remains that all the modifications of the earlier impracticable instruments which have rendered the examinations with the upright image easy and expeditious, were suggested and taken from Dr. Loring's original instrument."

Dr. Knapp alludes to my paper as a personal attack upon himself. Of course, all discussions involving the use of names are more or less personal. Whether it is better to make personal attacks which cannot be substantiated by facts in the presence of those who are unacquainted with the subject, or to print them in a regular medical journal—the only fair and neutral arena for medical disputes—is a matter of taste. And as these are confessedly not open to discussion, I shall say no more in regard to it. I have re-read my remarks, and can find nothing which is offensive in them to Dr. Knapp, unless it be their truth, but fortunately whatever the truth may be in law it is never a libel in science.

Very truly yours,  
EDWARD G. LORING, M.D.

### PHOSPHORUS ASSIMILATION.

MR. ROBERT W. GARDNER—*Dear Sir*:—In THE MEDICAL RECORD of May 19th, you answer the observations I made on 7th April to your paper on the above subject on January 27th.

You express yourself astonished that I should "dispute" what is "generally conceded by physicians," "that phosphorus must be given with the food or it will attack the mucous surface of the stomach."

I endeavor to base my observations on *facts*, and with such to support me I have many times "disputed" what is "generally conceded." Many years ago, in my early pupilage, I got the ill-will of many of our eminent physicians for asserting and *proving* that narcotine was not the narcotic principle of opium. I have "disputed" many other errors in therapeutics. I hope, for truth's sake, to "dispute" some of those which still exist. I have more reverence for truth than for "conceded opinions."

Free phosphorus, when administered in *medicinal* doses, is generally given in solution in some oleaginous substance, and when received into the stomach is absorbed with the oily globules, whether taken with

food or without it, and the irritant action it produces on the stomach shows itself with all its toxic effects quite as soon one way as the other. With a dose of  $\frac{1}{10}$  grain three times a day, the peculiar disagreeable eructations and irritability of the stomach is induced quite as quickly if given with several ounces of oil as with a drachm.

If you will look over the reported cases of poisoning by phosphorus, whether by administration of large doses, or the slower poisoning by smaller and frequently repeated doses, you will find that there are many instances where there are no lesions whatever upon the mucous lining of the stomach, but that hæmatomata are found upon the heart or pleura, or liver, or large intestines, the *serous* coat of the stomach, or elsewhere. In several cases I have reported, I have administered the oil, phosphor., undiluted and without food, and have found no lesion whatever upon the stomach, but the kidneys alone disintegrated from the effects of the poison. The same will be found in cases reported by Wegner and Köhler. These are facts, and worth more than all "conceded opinions" to the contrary. I am not much in the habit of giving free phosphorus *medicinally*, but I should have no fear that in the ordinary dose it would have any immediate local action upon the mucous lining of the stomach and if such "gastric irritability" and "undue irritant action" arose, it would be an after effect, localized there after the general system had become poisoned.

You say: "Dr. Percy denies that the irritant action of phosphorus is due to its oxidation." "Phosphorus exposed to the air takes fire. Why?" "Nobody disputes that it is because of its rapid absorption of oxygen." "Held in the hand, it burns the skin. Why?" "Undoubtedly by taking the oxygen from the cuticle thus disintegrating and destroying it. If it will burn the hand it will also burn the delicate mucous surface of the stomach, if in contact with it."

If you will turn to *Trans. Am. Med. Ass.*, 1872, pp 647 and 648, you will find the report of several cases where enormously large poisonous doses of free phosphorus were given in oil, and the animals recovered without the slightest injury by administering oxygen that is, by oxidizing the phosphorus and thus depriving it of its "irritant action." I believe I have proved that the only antidote we have to phosphorus is oxygen, that is, by its absorption of oxygen, "oxidation," it becomes mild and *non*-irritant. Köhler in his work on this subject published in the latter part of the same year, fully sustains me; he gives many cases of cures from phosphorus poisoning by administering *oxygenated* oil of turpentine, but he states that the turpentine unoxxygenated will not give relief. Have I not facts to support me when I "deny that the irritant action of phosphorus is due to its oxidation? Again I "dispute" "conceded opinions."

If you will poison any worthless animal with phosphorus, and dissect it, your nose alone will soon give you proof that the phosphorus has not become "oxidized," but that it remains in the system in the same state that it was taken. If it were oxidized, it would not smell, and it would no longer be an irritant. There have been several cases reported where bodies have been quite luminous after poisoning by phosphorus.

"Phosphorus exposed to the air takes fire. Why? Held in the hand, it burns the skin. Why?"

I feel satisfied that you wrote this in a hurry, and without due consideration. Phosphorus is never given medicinally in its pure state, but in solution in oleaginous substances. If a saucer full of this phosphoretted oil is left exposed to the air for a year

will not take fire; and if the hands are dipped in it, it does not ignite or burn the skin. If this "hypothesis" of yours were true, we should, under all circumstances, when we give oil, phosph., have numerous little fires kindled in the stomach, and even if the oil were mixed with food, it would only make the fires smaller, but more numerous.

I grant that "dyspepsia and gastric irritability" follow its use, not on account of its oxidation and setting fire to the stomach, but owing to its absorption without becoming oxidized. It is an irritant! Arsenic also is an irritant of somewhat different character.

You say: "I deny that the phosphates derived from vegetable sources in any way differ from the (same) phosphates obtained elsewhere." I have withheld the word *same* from your sentence, because I have nowhere asserted that they are the *same*. I have said they are very different, and you differ with me for this assertion. We are all aware that man and animals throw off by their excretions large amounts of phosphates; these phosphates have been used and accomplished their purposes in the system, and have been changed in their formula from active nutrients to inert excrements; by the changes they have undergone, they are incapable of affording further nutrition, they are no longer needed in the system, are thrown off, and we use them upon our farms, and by their use vegetables grow freely, while without their use our lands soon become barren.

The animal has thrown off an inert and used up phosphate, and it must again go through organization or *vitalizing* in plant life before it becomes adapted to nourish and support animals. The *phosphoids* in our system are derived from the foods we eat, and the richer and more "complex" these phosphoid elements, the more nutritious we find the vegetables.

You deny that "the phosphates derived from vegetable sources in any way differ from the phosphates obtained elsewhere," and yet you acknowledge that you have never made an analysis to test this assertion, or even read authorities to which you were referred. I have made many analyses for the peculiar phosphoid elements contained in plants, and I have found some of them to differ, and differ materially, from laboratory compounds of phosphorus. Some of the animal phosphoid compounds differ also from any laboratory compounds. If you will enter into such "realms of metaphysics" and examine "the physiological action" of plant life, you will no longer doubt that plants have the power appropriate from the soil the effects and immutability of phosphates excreted by animals, and elaborate them into a higher organized phosphoid element which is suited to its own growth and reproduction, and the nourishment of animals. This is common-school literature. Read Bryant's *Forest Hymn*.

I was not aware that you had in the market a group of the hypophosphites, and therefore could not in any way refer to impurity in it, and I have no doubt, from your lucid chemical explanations regarding it, that it is strictly all it is represented, and yet you acknowledge that all that are made with the commercial salts are as impure as I represented them.

You say: "Although combinations are frequently required, this is one objection I make to Dr. Percy's complex formula."

I would refer you to Thudicum's most admirable work on the Chemical Analysis of the Brain. As in every other analysis of animal or vegetable organs, will there be seen that the nitrogen phosphoid

elements are not simple; they do not consist of simple neutral hypophosphites of lime, or soda, but they are very complex in their character, and that complexity I have endeavored to maintain in the "Vitalized Hypophosphites." Were it within the province of this paper, I could give numerous recommendations of its inestimable benefit from physicians who have used it largely, that would silence all objections to "its complex formula."

The error of combinations in our remedies is in their incompatibility, not in their "complexity."

This puts me in remembrance of an observation made several times by my most worthy preceptor, Professor J. B. Beck: "The woman who invented turtle soup and plum pudding ought to be immortalized; some are foolish enough to think them a heterogeneous compound; the initiated know them to be a homogeneous whole."

Again I say I am happy to read your criticism. There are some things in which we do not agree, but I hope it makes us both better and wiser to discuss them.

I am, most respectfully,  
SAMUEL R. PERCY, M.D.

47 WEST THIRTY-EIGHTH ST.

## ONE-SIDED ACTION OF BELLADONNA.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—In addition to the two cases of one-sided action of belladonna reported on page 334, vol. 12, of THE MEDICAL RECORD, allow me to present another, which occurred in my own person.

Some six (6) weeks since, while suffering from an attack of tri-facial neuralgia—left side—I began taking, internally, of the alcoholic extract of belladonna, gr.  $\frac{1}{2}$  thrice daily.

About noon of the second day I noticed some disturbance of the vision, but thought nothing of it, as such a result was to be expected; but some hours after I accidentally discovered that the disturbance seemed to be wholly confined to one eye, the right, and going to a looking-glass found the right pupil widely dilated, not responding in the least to alternate light and shade, while the left was in a perfectly normal condition and responded readily to light and shade.

I continued the remedy for about one week, the right pupil remaining fully dilated during the whole of this time, and for two or three days subsequent to its discontinuance, while the left pupil failed to—at any period of the time—show the characteristic effect of the drug.

J. NEWTON SMITH, M.D.

GOSHEN, INDIANA, JUNE 5, 1877.

## ARMY NEWS.

*Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from June 10 to June 16, 1877.*

SUMMERS, J. E., Surgeon and Medical Director. Granted leave of absence for one month. S. O. 76, Dept. of the Platte, June 9, 1877.

PAGE, CHAS., Surgeon. To perform the duties of Medical Director of the Department during the absence of Surgeon Summers. S. O. 76, C. S., Dept. of the Platte.

ALEXANDER, C. T., Surgeon. Assigned to temporary duty at these headquarters, and to accompany the Department Commander during existing field operations. S. O. 62, Dept. of the Columbia, May 29, 1877.

VICKERY, R. S., Asst. Surgeon. Assigned to temporary duty at Fort Hamilton, N. Y. H. S. O. 131, Div. of the Atlantic, June 15, 1877.

MOFFATT, P., Asst. Surgeon. Assigned to duty at Fort Mackinac, Mich. S. O. 131, C. S., Div. of the Atlantic.

PAULDING, H. O., Asst. Surgeon. Relieved from field duty, and to resume his duties as post surgeon, Ft. Ellis, Montana Territory. S. O. 71, Dept. of Dakota, June 5, 1877.

TORNEY, G. H., Asst. Surgeon. To accompany battalion 16th Infantry from New Orleans, La., to Fort Leavenworth, Kansas, remain on duty with regiment, and await orders from A. G. O., relieving him from duty in the Dept. of the Gulf. S. O. 97, Dept. of the Gulf, June 7, 1877.

## Medical Items and News.

CONTAGIOUS DISEASES.—Comparative statement of cases of Contagious Disease reported to the Sanitary Bureau, Health Department, for the two weeks ending June 16, 1877.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-Spinal Meningitis.	Measles.	Diphtheria.	Small-pox.
June 9 . . . . .	0	3	75	3	62	29	4
“ 16 . . . . .	0	3	99	2	52	40	2

DR. J. W. BARSTOW, Medical Superintendent of Sandford Hall (lunatic asylum), Flushing, L. I., gave a reception on Saturday last to the members of the Medical and Surgical Society and several medical friends. After inspecting the grounds and the buildings, a bountiful repast was served, and altogether the affair was an enjoyable one.

DR. FRANK H. HAMILTON, President of the Medico-Legal Society, signalized the last meeting of that body, June 13th, previous to its vacation, by a reception to Dr. Isaac Ray, of Philadelphia, the distinguished medical jurist, who read a paper in the earlier part of the evening on Testamentary Capacity.

OUR SOCIETY REPORTS.—The necessity for finishing up the reports of the Sections of the American Medical Association has compelled us to crowd out other material.

DEATH FROM BLOOD-TRANSFUSION.—An inquest has been recently held at Liverpool on the body of a man named Walter Robert Williams, who died after having some of his blood transfused to another man, who was in a very weak state. The operation took place a few days ago, and the deceased went on well for a day or two afterwards. He then became ill, got gradually weaker, and died May 24, from erysipelas. The deceased was a man of full habit, and it was stated that he was occasionally given to drinking. The surgeon who performed the operation said that, before doing so, he made particular inquiries from the deceased as to his habits and state of health, and his answers were satisfactory. Witness thought him a remarkably fit subject. The general medical evidence was to the effect that the operation had been skilfully performed. Mr. Higginson said he had performed the operation successfully in fifteen cases. The jury returned a verdict of “Death by misadventure,” but

they were also of opinion that sufficient inquiry was not made by the medical men who made the operation as to the deceased's habits and physical condition, and that he was not sufficiently cautioned as to the risk he was running. Together with this report, we receive at the same time a little pamphlet by Dr. Roussel, advocating the more frequent practice of transfusion by the aid of his now well-known instrument, with a few introductory words of recommendation by one of the most thoughtful of surgeons, Sir James Paget, who adds the following words, on which the above accident furnishes a striking commentary: “As to any damage to be sustained by the person who gives the blood for transfusion, no fear of this can be felt by any one who, like myself, many years ago, bled healthy people in any number without harm.”—*British Medical Journal*.

DEATH UNDER ETHER.—An inquest was held May 23d, in the case of a man aged 69, who was admitted into the London Hospital with strangulated hernia of three days' duration. It was evident that strangulation existed, although the hernia had been reduced, as he was constantly vomiting, and the abdomen was tense and tender. He was so much exhausted that it was a question how far he would bear any operation. Ether was administered by Clover's inhaler, first allowing air only to be admitted, then a small quantity of ether-vapor. He did not take it well, and struggled much. Air was then admitted freely; and, although respiration continued a short time, the pulse became weaker and finally stopped. Silvester's artificial respiration and other restorative measures were tried, but failed. Not more than two drachms of ether were used. On *post-mortem* examination, the heart was found flaccid, and the left ventricle uncontracted; the lungs were extremely emphysematous, and the bronchi filled with muco-purulent matter. These and other morbid changes, both chronic and acute, might be considered sufficient in themselves to account for death. The facts, therefore, would not warrant the conclusion that death was due to the administration of ether. Several coils of intestine were strangulated by two long bands of omentum twisted round them spirally and adherent to the sac, which had been inverted and pushed up into the peritoneal cavity. An additional explanation of the sudden collapse was afforded by the fact that the relation of the parts was so peculiar that traction on the scrotum, in attempting reduction, pulled down the sac, and tightened the bands around the mass of intestines to an extreme degree. The jury returned a verdict of death from accidental causes.—*Ibid*.

MEDICAL SOCIETY OF ROCKLAND COUNTY, N. Y.—At the meeting held May 29, 1877, the following officers were elected for the ensuing year:

President—Dr. J. J. Stephens, of Tappan; Vice-President—Dr. I. C. Waring, of Clarkstown; Secretary—Dr. William Govan, of Stony Point; Treasurer and Librarian—Dr. I. S. Wigton, of Spring Valley; Censors—Drs. I. O. Polhamus, E. H. Maynard, and I. C. Waring; Delegate to American Medical Association for 1878—Dr. William Govan.

IOWA STATE MEDICAL SOCIETY.—At Annual Meeting of this Society, held at Cedar Rapids, May 30th, and 31st, the following officers were elected for the ensuing year: President—H. Ristine, of Cedar Rapids; Vice Presidents—J. W. Gustine, Carroll City, and L. P. Fitch, Charles City; Secretary—J. F. Kennedy, Des Moines; Assistant Secretary—G. O. Morgridge, West Liberty; Treasurer—G. R. Skinner, Cedar Rapids.

**HOT WATER A REMEDY FOR POST-PARTUM HEMORRHAGE.**—Dr. G. Jacobi, late graduate of Bellevue College, now assistant of Professor Schroeder, in Berlin, writes to his preceptor, Dr. Waterman, as follows: "I attended, last night, in the lying-in hospital, a case of profuse post-partum hemorrhage, which I was unable to control with the usual means, and had to send for Professor Schroeder, who immediately arrested the bleeding by an injection of hot water, 50° C."

**UNIVERSITY OF PENNSYLVANIA, MEDICAL DEPARTMENT.**—Prof. Theodore G. Wormley, of Columbus, Ohio, has been elected to the Chair of Chemistry, made vacant by the resignation of Dr. Rogers; and Dr. John Ashhurst, Jr., to the Chair of Clinical Surgery. The Chair of Physiology will be filled temporarily by Prof. James Tyson. Dr. John M. Keating has lately been elected to lecture on Diseases of Children, in the spring course.

**NEW JOURNALS.**—Our exchange list has recently been enriched by two new journals: *La Province Médicale*, and the *Revue Médicale Roumaine*. The former, which is published at Bordeaux, is started with the design of supplying the profession in that city, and in its neighborhood, with more detailed and satisfactory accounts of what is being done in the great medical centres of the world than have been furnished by the two medical journals already published there. The *Revue Médicale Roumaine*, which is published at Bucharest, will take cognizance of all questions relating to the medical sciences. Its end is to keep the profession in other countries informed of the progress of medicine in Roumania, and also to bring to the notice of its compatriots the results of the scientific investigations and practical experience of foreign observers. The present number (March 19) contains the history of a fatal case of nervous hydrophobia. The patient, a child, was frightened, but not bitten, by a dog that was not rabid. The symptoms were in the main those of hydrophobia, but presented many deviations from the typical course.

We have also received the *St. Petersburger Medicinische Wochenschrift*, which, though new to our exchange list, has been in existence for some time. In addition to the usual original articles, etc., the editors of the journal intend from henceforth to furnish for the benefit of foreign readers a weekly review of Russian medical literature, including both periodicals and separate publications. This review will be made as complete as possible. One of its editors is well known by his able editorship of the *Dorpatser Medicinischer Zeitschrift*.

**COMPARATIVE PROTECTION OF VACCINATION AND VARIOLA.**—Dr. Wm. Badger, of Flushing, L. I., writes: "In the issue of your journal, May 19th, an article with the above caption. In confirmation of the fact there stated, allow me to mention briefly, that during our civil war I selected some twenty hospital patients for vaccination on the succeeding day. The next morning I found among them, on some unknown reason, an extra man, with arm sore for the operation, whose face was unusually disfigured from small-pox. Remarking that I was willing to accommodate him, although it was unnecessary, I vaccinated him with the others, and thought no more about it until the eighth day, when, on examining the men, I found that the most characteristic appearance was on the arm of this pock-marked man. A few years since, there was living in New York City, a lady, an intimate friend of my family, who had suffered from variola, or varioloid, three times, at intervals of several years.

"Other instances of the recurrence of variola are by no means as infrequent as generally supposed, and I should not think of employing a nurse who has had small-pox to care for a similar case without revaccination."

**DEATH FROM CHLOROFORM.**—*The Medical Press and Circular*, of Dublin, in commenting upon the recent deaths from chloroform in London, says: "We often hear chloroform deaths spoken of as simple mischances, of which every hospital surgeon must bear his share, and of which a few more or less must be looked upon as a run of bad luck; some surgeons even go further, and talk of occasional chloroform deaths as a sort of penalty which the operator pays for permission to use a rapid and convenient anæsthetic. We speak not only for the profession but for the public, when we say that such a view of looking at the sacrifice of life by anæsthetics is worse than inhuman. It is criminal and it is unscientific, and so much so as to justify the stern interference of the law and the summary punishment of those guilty of culpable negligence. We advisedly repeat that the anæsthetist who gives, or the operator who permits to be given, an anæsthetic without the most anxious thought as to the fitness of the patient to receive it, the safety of the agent itself, and the suitability of the means of administration, is responsible in the highest legal and moral senses for the result. We solemnly protest against the 'ready method' of anæsthesia by a dash of chloroform on a towel, and without any close examination into the case or careful inquiry as to the safety of the administration, and we are strongly of opinion that the time has come to put in force all the coercion of which the profession is capable for the purpose of checking the daily sacrifice of life by careless dosing with chloroform."

**KENTUCKY INFIRMARY FOR WOMEN AND CHILDREN.**—At a meeting of the Board of Regents, Kentucky Infirmary for Women and Children, held May 15, 1877, the following persons were elected to serve for the ensuing year:

*Medical Staff.*—Dr. David Cummins, Deformities and General Surgery. Dr. Geo. W. Griffiths, Diseases Peculiar to Women and Children. Dr. Richard C. Brandeis, Diseases of the Eye, Ear, and Throat. Dr. Ely McClelland, Pelvic Surgery. Dr. Samuel Brandeis, Surgeon Accoucheur. Dr. James McEvoy, Clinical Assistant. *Dental Staff.*—B. Oscar Doyle, D.D.S.; W. T. Redman, D.D.S., M.D.; Ch. E. Dunn, D.D.S.; W. T. Goddard, D.D.S.; C. G. Edwards, D.D.S.

**LACTO-PHOSPHATE OF LIME AS A TOOTH-FILLING.**—The treatment of exposed dental pulps and sensitive dentine is the subject of an interesting paper by Junius E. Cravens, D.D.S. The lacto-phosphate of lime is applied to the exposed pulp, which is carefully sealed and left undisturbed for several weeks. On removing the coverings a new bone is found, its surface continuous with that of the formerly soft dentine, and the sensibility being even below the normal degree. Oxy-chloride of zinc and other substances, however, may produce like results.

**SALICIN IN CANCER OF STOMACH.**—Dr. A. E. Hull, of Berlin, N. Y., writes: "I wish to call attention to the great relief obtained in a case of carcinoma of the stomach from the use of salicin. The pain and vomiting was very severe, and the only way in which an anodyne (morphine) could be retained, was to administer it in a state of effervescence, and then only for a short time, and under these circumstances the patient suffered greatly from the pain in the stomach and the annoyance of vomiting. At this stage I began giving small doses of salicin, perhaps half a

grain every three hours, and to my surprise there was marked relief from both the pain and vomiting from the first powder, which was given in a little water and was perfectly retained by the stomach. Patient continued to take the salicin as long as life lasted, about five weeks, and enjoyed a degree of ease and comfort that was not to be anticipated. I am not aware that salicin has ever before been given for relief in this disease, neither do I pretend to say just what the *modus operandi* of the remedy was that gave such relief in this case, but think it must be owing to the anaesthetic and antiseptic properties of the salicylic acid contained in the salicin.

"As this is the only case in which I have had a chance to use the salicin in carcinoma of the stomach, I hope other physicians who may have an opportunity will give it a fair trial and report their results.

"The dose of salicin was increased some during the five weeks the patient took it, but at no time did it exceed two grains."

**THE NEW YORK ACADEMY OF SCIENCES AND PHYSIOLOGICAL EDUCATION.**—The New York Academy of Sciences has taken hold of the question of physiological education in a way that promises to result in some practical good. The following conclusions commend themselves to the serious attention and cordial support of the medical profession:

The undersigned, a committee of the New York Academy of Sciences, appointed at the instance of Dr. Edward Seguin, to suggest methods by which the public parks of New York could be made most useful to the citizens, respectfully submit the following resolutions:

*Resolved*, I. That the public parks of New York, like those of every other great city, are of inestimable value to the physical and moral health of the citizens, and should be carefully guarded from every kind of encroachment and misuse.

*Resolved*, II. That the parks of New York should not only be made attractive places of resort, but should be so arranged and planted as to be schools of taste and means of scientific instruction. To accomplish these ends, they should not only be made beautiful to the eye, but so stocked with plants and animals as to give to those who visit them impressive views of the variety and system of nature. Hence they should contain, not merely masses of common plants, serving the purpose of so much vegetation in the landscape, but that vegetation must include as large a number as possible of plants of scientific and economic interest, and those so arranged and labelled as to educate the understanding as well as to please the eye.

*Resolved*, III. That since it is a well-established truth that certain kinds of vegetation exert a powerful purifying influence upon the atmosphere, efforts should be made to introduce these sanitary agents for the purpose of neutralizing the malaria which pervades so much of the city and environs of New York, and that, to accomplish this object, we should seek to acclimatize such febrifuge trees as the Eucalyptus, not now hardy here; or to introduce plants of this tree taken from some higher and colder station than those from which they have heretofore come.

*Resolved*, IV. That special arrangements should be made to facilitate the free use of our parks as garden-schools, by the children now too much confined in our public school buildings; and that some competent physiological and hygienic control should be established to guard against the evils which the weaker pupils constantly suffer from too great crowding and too long confinement in the school-room.

*Resolved*, V. That the members of the Academy of

Sciences have heard with great pleasure of the inception of a movement for the establishment of a Botanical Garden in connection with the Central Park, believing that this would add much, both to the attractiveness and utility of this great place of resort.

*Resolved*, VI. That copies of the foregoing resolutions be transmitted to the Mayor of the city, the Park Commissioners, the Board of Health, the Board of Education, and the Trustees of the Botanical Garden, with the assurance that the members of the Academy of Sciences will gladly co-operate in any possible way for the accomplishment of the object suggested in these resolutions.

**THE PERIODICAL INTERNATIONAL MEDICAL CONGRESS** will hold its fifth session at Geneva, commencing Sunday, September 9th, and ending September 15th. The following papers are announced:

In the *Section of Medicine*: 1. Ulcers of the Stomach, Prof. Lebert. 2. Parasitic Affections of the Skin, Prof. Hardy, of Paris. 3. Etiology of Typhoid Fever, Prof. Bonchard, of Paris. 4. Treatment of Fever by Baths, Dr. De Crenville, of Lausanne. 5. On the Tissues Implanted in the Organism, Prof. Zahn of Geneva. 6. Indications and Therapeutic Value of Tracheotomy in Croup, Prof. Revilliod. 7. A Universal Pharmacopœia, Prof. Gille, of Brussels. In the *Section of Surgery*, are: 1. Esmarch's Hemostatic Method, Prof. Esmarch, of Kiel. 2. Influence of Traumatism on Pregnancy and vice versa, Prof. Verneuil, of Paris. 3. Treatment of Ozœna, Dr. Rouge, of Lausanne. 4. Final Results in Resections of Joints, Dr. Ollier. 5. Galvano-Cautery, Prof. Julliard, of Geneva. 6. Apparatus for the Transport of the Wounded. 7. Fistulas of the Penis, Prof. Reverdin, of Geneva. In the *Section of Obstetrics and Gynecology* there are the following announcements: 1. Placental Souffle, Dr. Rapin, of Lausanne. 2. Artificial Alimantation of Young Infants, Prof. Zweifel. 3. Anæsthesia During Labor, Dr. Pichaud, of Geneva. 4. On the Law of Growth in Young Children During their First Year, and its Physiological or Pathological Deviations, Dr. Odier, of Geneva. 5. Pseudo-Membranous Dysmenorrhœa, Dr. Gautier, of Geneva. In *State Medicine* there are: 1. The Influence of Alcoholism on Mental Maladies, Dr. Magnan. 2. The Influence of the Adulteration of Alcoholic Liquors on the Health of those who Make and those who Consume Them, Dr. Gillaume, of Neuchâtel. 3. Questions in Medical Geography, Dr. Lombard of Geneva. 4. The Influence of the Immigration of People from the Country into Cities, Prof. Dumant, of Geneva. In the *Biological Section* there are: 1. Physical Characters of the Electrical Discharge of the Torpedo; Physiological Analogies between this Discharge and Muscular Contraction, Prof. Marey, of France. 2. Cerebral Localizations, Dr. Broadbent. 3. On the Cause of Sleep, Prof. Preyer, of Jena. 4. Human Entozoa, Prof. Vogt, of Geneva. 5. The Function of the Spleen, Prof. Schiff. 6. Histology of the Egg, and the Rôle of the Zoöspers in Fecundation, Dr. Fol. 7. Physiological Antagonism, Prof. Prevost, of Geneva. In the *Section of Ophthalmology*, etc., there will be: 1. Indications for Enucleation of the Globe of the Eye in Relation to Sympathetic Ophthalmia, Dr. Warlomont, of Brussels. 2. Etiology and Prophylaxis of Myopia, Dr. Haltenhoff, of Geneva. 3. What are the Best Methods for Determining the Range of the Principal Functions of the Eye: (a) Acuity; (b) Perception of Color; (c) Refraction and Accommodation (d) Field of Vision, and (e) Mobility of the Eye, Dr. Fol, of Geneva. 4. Tenotomy of the Tensor Tympani, Dr. Colladon, of Geneva.

## Original Lectures.

## LECTURES ON FEVERS.

By ALFRED L. LOOMIS, M.D.,

PROFESSOR OF PATHOLOGY AND PRACTICAL MEDICINE IN THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF THE CITY OF NEW YORK.

(Phonographically reported for THE MEDICAL RECORD.)

## LECTURE IX.

TYPHO-MALARIAL FEVER (CONTINUED)—SYMPTOMS—DIFFERENTIAL DIAGNOSIS—PROGNOSIS—TREATMENT.

GENTLEMEN: I have mentioned the prominent symptoms which attend the development of that type of typho-malarial fever in which the malarial element predominates, and will now speak of those present in the septic type of this fever. Although the premonitory symptoms of this type, such as lassitude, headache, pains in the back and limbs, resemble those of typical typhoid fever, either a distinct chill or a complete intermittent or remittent paroxysm ushers in the febrile symptoms.

The rise in temperature following the ushering-in chill has no typical range; in some cases the rise is gradual, not reaching its maximum before the middle of the second week; in other cases the rise is sudden, reaching 104° F. or 105° F. within twenty-four hours after the occurrence of the chill. Throughout the whole course of the fever the same tendency to periodicity exists, which was noticed in the malarial type of this fever.

In typhoid fever, during the first week, there are indistinct forenoon remissions and afternoon exacerbations, but in this fever the remissions are well marked, especially on every second or third day, causing the fever to assume a more or less distinct tertian or quartan type. One of the earlier symptoms in this fever is well-marked hepatic tenderness; with the hepatic tenderness there is enlargement of the spleen, which, as the fever progresses, reaches a much larger size than is ordinarily met with in typhoid fever. During the first week the pulse is full and rarely more than 100 beats per minute, but during the second and third weeks it is small and compressible, and in severe cases is intermittent, and ranges from 110 to 130 per minute. The appearance of the tongue varies with the period of the fever. At first it is swollen, with red projecting papillæ, and has a light white coating. As the typhoid condition becomes more prominent its appearance changes; it becomes dry and brown, and frequently the brown coating cracks, and fissures are formed in the mucous membrane underneath. Should the tongue become moist and begin to clean, you may regard convalescence as established. The coating is removed in two ways, either gradually from the edge to the centre, or it is thrown off in flakes. In the latter case, after the removal of the coating, the tongue assumes a beefy red appearance, and after a short time may again become brown and dry. Under such circumstances there will be a renewal of the typhoid symptoms.

After the fever has continued a few days the surface becomes dry and harsh, and the skin assumes a bronzed hue, which is quite characteristic of this fever; sometimes, instead of this bronzed hue of the surface, there is well-marked jaundice.

The changes in the urine do not differ from those which usually attend febrile excitement. The urine gradually diminishes in quantity and deepens in color until convalescence commences, when it increases in

quantity until convalescence is reached. It is rarely albuminous.

*Diarrhœa* may occur at any period. It is not usually excessive until the second or third week. There is nothing characteristic about the discharges. They are usually of an exceedingly fetid odor, watery, and dark colored; in the later stages of the disease they sometimes contain blood. In some instances the character of the stools is termed bilious, and an excessive hepatic secretion is then indicated; at other times they are of a dark clay color, showing a deficiency of the biliary secretion. With the diarrhœa there is usually more or less abdominal tenderness, especially in the right iliac region, but the tympanitis, which is so constant an attendant of typhoid fever, is rarely well marked in typho-malarial fever. In many cases there is retraction of the abdomen.

As I have already stated, headache is a very constant and prominent symptom in the early period of this fever. It often precedes the ushering-in chill. As the fever progresses it gives place to a delirium, which is never violent, but which is muttering in character, and is attended by restlessness and insomnia, or by drowsiness, subsultus, picking at the bed-clothes, and great nervous depression. If delirium is not present, or after it has disappeared during convalescence, there is great lack of mental vigor, and a tendency to mental sluggishness. The other nervous phenomena, which usually are present in any condition when marked typhoid symptoms exist, are not prominent in this fever. The subsequent phenomena which may attend its development will vary with the intensity of the fever and the resisting power of the patient.

In fatal cases, toward the close of the second week, symptoms of extreme prostration come on, the patient gradually passes into a state of stupor, which lapses into a state of coma, and death ensues.

In cases that are to recover, by the end of the second week the tongue begins to clean, the gastric and intestinal symptoms, with the exception of the diarrhœa, begin to subside, the pulse becomes slower, the nervous disturbances disappear, the appetite returns, and the patient enters on a convalescence which is usually protracted.

It is apparent that the early stage of this fever very closely resembles that of simple remittent, while its later stage as closely resembles that of typhoid.

The phenomena of both stages may be modified by certain anti-hygienic surroundings to which those suffering with this fever may have been subjected prior to its development. Thus, when it prevails among those who have suffered privations, been badly fed, badly clothed, overcrowded in badly ventilated apartments surrounded by decomposing animal and vegetable substances, although the fever is attended by the same general phenomena which characterizes the typhoid type, there are certain variations which ally it to relapsing fever. Prominent among these are neuralgia and arthritic pains in various parts of the body, especially in the back and limbs, hemorrhagic tendencies, marked by bleedings from the gums, mucous surfaces, and not infrequently large ecchymoses occur in various parts of the body. In this class of cases from the commencement of the fever it is of low type, with quotidian exacerbations and remissions. Diarrhœa usually precedes the development of the febrile symptoms. Frequently, during the second week, a muttering delirium comes on, accompanied by drowsiness and a tendency to stupor. Despondency, indisposition to make any exertion, and a state of utter indifference as to the future, is frequently met with during the entire period of the fever.

In fatal cases, death may be the result of hemorrhage from the mucous surfaces, or from exhaustion. In this class of cases there is a great irritability of the heart and a peculiar mental and physical prostration.

In cases that recover, convalescence comes on late, and is slow and tedious. Diarrhoea frequently follows the subsidence of the fever, which in many cases cannot be controlled, and leads to a fatal result.

The complications which may modify the course of any variety of typho-malarial fever are very similar to those which are met with in typical typhoid fever. Of these the most frequent is inflammation of the respiratory organs, the development of which is marked by those symptoms which usually attend the development of the different acute pulmonary affections. In the majority of instances the signs of bronchitis are not present until the fever is well established. The bronchitis resists treatment, and does not disappear until convalescence is fully established. When pneumonia occurs it is catarrhal in character, and few of the strongly marked rational symptoms of ordinary pneumonia are present. The physical signs, however, will always enable you to determine the presence of pulmonary complications, and any great irregularity in the clinical history of this fever should lead you to make a careful physical examination of the chest.

It is sometimes difficult to distinguish between the cerebral symptoms of this fever and those symptoms which attend meningeal complications, but the meningeal complications are of very rare occurrence, and it is safe to assume that they are not present until some of the diagnostic symptoms of meningitis occur.

We rarely have serious abdominal complications, such as intestinal perforation, peritonitis, and hemorrhage, and their advent is marked by such urgent symptoms that one loses sight of the ordinary symptoms of the fever.

It is hardly necessary for me to refer to those modifications in the clinical history of this fever which follow the development of abscesses, bed-sores, gangrene, etc.

*Differential Diagnosis.*—The affections with which typho malarial fever are likely to be confounded are typhoid, remittent, relapsing, typhus, and yellow fevers.

The septic type of typho-malarial fever, in many of its phenomena, so closely resembles typhoid fever that frequently it is difficult to make a differential diagnosis. I will briefly state the points of difference in their clinical history.

The advent of typho-malarial fever is usually marked by a distinct chill, while typhoid comes on insidiously, and is not attended by a distinct chill, only by a chilly sensation. The rise of temperature in typho-malarial fever is sudden and follows no typical range, while in typhoid the typical range of temperature during the first week is almost diagnostic of the fever.

In typhoid fever, on the sixth or eighth day, rose-colored spots appear; these are a distinctive mark between it and typho-malarial fever; although in the latter an eruption may be present, yet it has none of the characteristics of the typhoid eruption, is not rose-colored, does not disappear on pressure, and remains visible throughout the whole course of the fever.

Besides the absence of these characteristic symptoms of typhoid fever, in typho malarial fever we have a distinct periodicity in the febrile action, a certain icteroid hue of the skin, hepatic tenderness, extensive splenic enlargement, and great gastric disturbance; conjoined with these, the appearance of the tongue, the character of the diarrhoea, and the non-infectious character of the stools in typho-malarial fever serve as

important aids in the differential diagnosis of these two forms of fever. In typho-malarial fever, upon microscopical examination of the blood, we find free pigment; this is never found in the blood in typhoid fever.

The malarial type of typho-malarial fever resembles remittent fever in its ushering-in symptoms. In both cases there is a chill followed by fever, attended by one or more distinct exacerbations and remissions. The early appearance of the enteric symptoms, attended by other well-marked typhoid phenomena by the end of the second week, establishes the diagnosis of this type of malarial fever, and as the fever progresses the typhoid condition becomes more and more apparent. Besides, remittent fever yields more promptly to the use of quinine than does typho-malarial fever.

Severe cases of typho-malarial fever, which are complicated by scorbutic tendencies, marked by petechie and great prostration of the vital powers, may be confounded with typhus fever; yet the severity of the attack, the higher range of temperature, the greater frequency of the pulse, the dusky countenance, the absence of diarrhoea and all other abdominal symptoms in typhus fever, renders it easy to make the differential diagnosis of the two types of fever. Besides, typhus fever has a characteristic eruption, is only propagated by contagion, and if it prevails, does so epidemically. Occasionally yellow fever has been confounded with typho-malarial fever, and on this account I will mention some of the prominent diagnostic symptoms of yellow fever which distinguish it from typho-malarial fever.

The range of temperature is lower in yellow than in typho-malarial fever, and on the third or fourth day it falls markedly lower, and there is more or less complete remission. The circumorbital pain, the appearance of the eye, the peculiar color of the skin, the character of the matter vomited, the absence of diarrhoea, the presence of albumen in the urine, and the shorter duration of the disease, will enable you to make the diagnosis of yellow fever. Again, yellow fever usually prevails epidemically, and is confined to certain localities and certain seasons of the year. It is a portable disease, and the yellow fever poison may be conveyed from an infected to a non-infected district by means of clothing or merchandise, while the poison of the typho-malarial fever is of endemic origin, and cannot be carried beyond the infected district.

The points of differential diagnosis between typho malarial and relapsing fever will be considered under the head of relapsing fever.

The differential diagnosis between cerebro-spinal meningitis and typho-malarial fever is sometimes attended with great difficulty.

*Prognosis.*—The ratio of mortality in typho-malarial fever varies greatly in the different regions in which it occurs, and according as the malarial or septic element predominates. The hygienic surroundings of the patient and the range of atmospheric temperature will also very greatly influence your prognosis. Statistics of this fever in different localities and in different years give the ratio of mortality from one in twelve to one in twenty-four. The septic type is more fatal than the malarial type. Great caution should be exercised in prognosticating the result of any case, for the apparently mildest cases sometime suddenly assume a severe type and terminate fatally; while very severe and apparently hopeless cases unexpectedly improve, and recovery takes place.

The average duration of these cases which terminate in recovery is from three to four weeks; it

duration varies with the different types of the fever. In the malarial variety the duration is always shorter than in the typhoid. The period of convalescence is prolonged; three or four weeks often elapse before the patient is completely restored to health. A fatal relapse may occur at any period during convalescence. In those cases that terminate fatally, death most frequently occurs during the second or third week; it may occur as late as the close of the sixth week.

The occurrence of any of the complications to which I have referred as possible during the course of this fever will very materially influence the prognosis in any given case. Capillary bronchitis and pneumonia are especially dangerous when they develop during the third week of the fever.

Anti-hygienic surroundings, such as overcrowding and improper food materially affect the prognosis. If typho-malarial fever prevails among those who are crowded into badly-ventilated apartments, who from filth and improper nutrition have septic and scorbutic tendencies, the ratio of mortality is much greater than among those who are free from such complicating influences.

The symptoms which may be regarded as indicating an unfavorable termination are a continued high temperature, showing little or no tendency to remission; a very frequent, feeble, fluttering pulse; profuse diarrhœa, the discharges at times being involuntary and containing mucus, pus, and blood; a dry, red, cracked and fissured tongue; great drowsiness, with a tendency to stupor and coma, and the appearance of petechial spots on the surface of the body, attended by frequent hemorrhages from the lips, gums, and tongue. In a severe case, the occurrence of any of these complications renders the prognosis more unfavorable. The character of the prevailing fever will also greatly influence the prognosis in any given case. If the type of the prevailing fever is mild, or if comparatively few deaths have occurred, though the symptoms in a given case may appear unfavorable, recovery is probable. If, on the other hand, the type is severe, and many deaths have occurred, apparently mild cases will suddenly become severe, and the prognosis becomes unfavorable.

As I have already stated, the hygienic surroundings and the previous habits of the patient very greatly influence the prognosis. With drunkards, and those corrupted by vicious habits, a mild type of this fever will probably prove fatal.

**Treatment.**—The treatment of typho-malarial fever varies with its type. No plan can be presented which will be applicable to all cases.

As in other forms of disease, the first question that presents itself under the head of treatment is, cannot the development of this fever be prevented? While speaking of its etiology, I stated that its development is principally due to three causes—namely, malarial poison, overcrowding, and improper diet. In a large proportion of instances it is possible to do away with the last two causes. The overcrowding and the faulty diet may be prevented, and thus the septic poison which gives to this fever its typhoid type may be destroyed or its development prevented. The strict observance of hygienic laws in the localities where the fever prevails has in some instances entirely changed the type of the disease. Even after the fever symptoms have been well developed the removal of patients from anti-hygienic surroundings has frequently been attended by the most satisfactory results. When isolated cases of this fever are met with in localities apparently free from such sources of infection a careful search should be instituted, in order to

find the source of the infection. Defective sewerage and faulty drainage have been found to be fruitful sources of infection. The therapeutic measures which may be employed in the treatment of this form of fever vary with the type of fever and the peculiarities of each individual case. There are no specifics.

In those cases in which the malarial element predominates, the administration of quinine as an antiperiodic will produce the desired result, and in many instances arrest the progress or shorten the duration of the fever; but in those cases in which the septic element predominates, while quinine may act as an antipyretic, in the same way as it does in typhoid fever, it has no power to arrest the progress or shorten the duration of the fever.

In those cases in which the malarial element predominates, which are ushered in by a distinct chill, followed by one or two distinct remissions and exacerbations, during the first remission twenty or thirty grains of quinine, in two or three doses of ten grains each, should be administered every hour until the desired quantity has been given. If it is promptly and freely administered it seldom fails to produce a favorable result; usually the febrile exacerbations will not return, or if they do they are less severe, and in a few days entirely disappear.

In those cases which begin more insidiously and are developed more gradually, if there is a distinct periodicity to the febrile phenomena, without distinct remission, although, by the administration of quinine, you may not shorten the duration of the disease, yet the fever will run a modified and very much milder course.

If the first full doses of quinine fail to produce any effect in this class of cases, its administration in moderate doses, perhaps ten grains twice a day, must be continued for several days before it will markedly modify the severity of the fever. In no type of this fever does the quinine exert any specific influence except over the malarial element; the enteric phenomena are either not at all, or only indirectly, modified by the antipyretic power of the drug. Hence it is apparent that in those cases in which the malarial element is slight, and in which the typhoid element is prominent, while quinine fails to exercise any controlling influence over the progress of the fever, it will mitigate its severity, and act as more powerfully as an antipyretic than it will in any other form of continued fever.

It has been claimed by some that arsenic has a specific influence over typho-malarial fever, and that it exercises a peculiar and most beneficial effect upon the intestinal lesions, materially shortening the duration of the fever. There is little doubt but that arsenic, like quinine, acts beneficially in many cases of the malarial type of this fever, but unquestionably this beneficial effect is due to its acknowledged power over malarial affections, and not to any specific influence which it has over the fever. As an antiperiodic it is inferior to quinine.

The antipyretic treatment of typho-malarial fever does not materially differ from that recommended for the reduction of temperature in typhoid fever. It is of importance to remember that this class of patients do not bear well the prolonged application of cold to the surface, either by means of the cold bath or the cold pack, and that, unless the antipyretic power of quinine is added to the application of cold, very little benefit will be obtained from its employment. The danger resulting from the injudicious use of cold baths is greater in this than in any other infectious disease.

The rules for the administration of stimulants in

typho-malarial fever are the same as those given for their administration in typhoid fever. The effects of the first few doses should be carefully watched. They should never be given indiscriminately, for there is greater danger of over-stimulating in this than in any other fever. Their use is indicated whenever signs of heart-failure are present, such as a feeble pulse and an indistinct first sound of the heart. No fixed rule can be laid down as regards the quantity to be administered in any given case; it will vary with the type of the fever and the previous habits of the patient; it should always be administered at stated intervals. The period of the fever at which their administration should be commenced will also vary. In some cases, stimulants are never required, while in other cases, from the very onset of the fever, they are demanded. In the majority of cases their use is not indicated before the end of the second week. It must be borne in mind that alcohol is not a specific curative agent in this fever, but that the object of its administration is to support the heart power and prevent the vital powers from falling below the point at which reparative processes are possible. The use of stimulants is not necessarily contraindicated when delirium is present. Frequently after their administration the delirium will pass away, and only when it is decidedly increased by their use should they be abandoned.

The state of the bowels, skin, and kidneys demands the closest attention. If, early in the disease, the bowels are constipated, a calomel purge combined with ten or fifteen grains of quinine will often be followed by marked benefit. In any stage of the disease brisk purgation should be avoided. If diarrhoea is present, it should not be interfered with unless it becomes exhausting; then it should be checked by small doses of opium combined with astringents.

When the skin becomes dry and parched, if cold baths or packs are not admissible, the surface should frequently be sponged with tepid water. It has been proposed by some to apply oil to the surface two or three times every day, when, from extreme exhaustion or any other cause, bathing or sponging of the surface cannot be practised.

Special notice should be taken of the quantity and character of the urine. If it becomes scanty and high colored, or if there be a temporary suppression, it is of the utmost importance that the functions of the kidneys should be immediately restored. This can be best accomplished by the administration of digitalis combined with spirits of nitre. Sometimes retention may be mistaken for suppression of urine, unless a careful examination be made as to the condition of the bladder. Symptoms referable to disturbance of the nervous system sometimes require special treatment. If there is extreme restlessness, muscular twitchings, or active delirium, opium may be administered in full doses. The effect of the first dose must be carefully watched. If sleep soon follows its administration, and the delirium gradually subsides without any aggravation of the other symptoms, its use may be continued; if, instead of producing sleep, the patient becomes more wakeful, and the delirium is increased and more active, and the other symptoms are greatly aggravated, its use must be immediately abandoned. Under these circumstances chloral may be tried with great care.

Some claim that spirits of turpentine in the treatment of this form of fever has almost a specific power, while others regard it useful only as a stimulant. My own experience leads me to employ it only as a stimulant during the second and third week of the disease,

when there is great prostration and marked typhoid symptoms. It may be given as an emulsion in doses of twenty drops every two hours.

The diet best suited to patients with this fever is milk administered in the same way as was proposed in the case of typhoid fever patients.

Special complications occurring during typho-malarial fever must be met with such remedies as the condition of the patient and the peculiar complications may require.

## Progress of Medical Science.

THE PHYSIOLOGICAL POSITION OF COPPER.—Mr. Edward Clapton, in a letter to the *Lancet*, states that it is true that the systems of workers in copper may be saturated with the metal without any signs of interference with the health, but that this can hardly be considered the rule. A large proportion of them complain of habitual lassitude and giddiness, and a disinclination to go about when not at work, as other workmen do. Some of them are exceedingly thin and have unhealthy, sallow-looking complexions, an nearly all complain of more or less dyspepsia. It is a noticeable fact, however, that all kinds of wounds heal very rapidly in these men, though similar wounds in lead-workers are soon attended with suppurative and constitutional irritation. Mr. Clapton could not find that there had been a single instance known of cholera attacking these workmen, even in the worst epidemics; a similar immunity has been noticed in the copper foundries of Edinburgh and Paris. Copper, however, is not physiologically an astringent, for the workmen rarely suffer from constipation, and diuresis is common among them. They also perspire rapidly, the perspiration having a greenish color. I Pary has proved conclusively that the copper is absorbed into the system, and exists in the secretions well as in chemical combination with various tissues such as even the hair and bones. He has also shown that copper is a constant component element of the body. The reason, then, of the comparatively slight injury from this metal in large proportions is doubtless because the system can tolerate an excess of what is a natural constituent infinitely better than it can tolerate the introduction of what is entirely foreign, such as lead, arsenic, and mercury. But this comparative immunity does not apply to those preparations in which the copper in union with oxygen has been promoted by acid, or combined with fatty bodies, and especially by acetous fermentation. There is no danger in subsisting on cuprififerous articles of diet, such as bread, beefsteak, etc., or in breathing for a time the air of a factory when it is highly charged with bright particles of the metal, or in taking sulphate of copper daily for a considerable time, but there is great danger in taking even very small quantities of verdigris or emerald green, or any preparation of copper which may be used to give a light-green color to "timed peas" or any other article of food. With regard to the preserves which Dr. Hassall found impregnated with copper, it is well known that a large quantity of sugar which they contain renders them harmless, the experiments of Orfila and Davy having proved that sugar is a decided antidote to the poisonous action of copper. The same freedom from danger would not apply to vegetable acids or other substances in copper culinary utensils. Mr. Clapton had a patient at St. Thomas's Hospital, a sailor, who suffered fearfully from gastro-enteritis brought on by drinking lemon juice which had been kept in a c

tank. The rest of the crew suffered in a similar manner.

In France the action of copper has of late been the subject of frequent discussion in many of the societies. M. Laborde has found by experiments that if three or four grammes of sulphate of copper, thoroughly dissolved and filtered, be injected under the skin of a dog of medium size, it will cause death in from eighteen to twenty hours. The symptoms are: a certain amount of pain at the points of injection, contraction of the pupils, paralysis of the hind-quarters, gradual acceleration of the pulse and respiration, and death in a sort of prostration. At the autopsy of one of these dogs, M. Laborde found congestion of the heart, lungs, liver, and kidneys; these organs were impregnated and infiltrated with dark, sepia-colored blood, that presented the characters of septicæmic blood. A contraction of the neck of the bladder had rendered the animal anuric; the urine contained a large quantity of copper, and also blood-globules and albumen. The gastric mucous membrane was very much inflamed and covered with a dark, bloody fluid.

In the discussion on M. Laborde's paper, in which the above case was detailed, in the *Société de Biologie*, M. Galippe denied that the salts of copper are really a poison, though he of course admitted their caustic action. He maintained that in the above case the death was due to the local lesion and not to a veritable copper intoxication, and further that it is impossible to poison a man with sulphate of copper without his knowledge. The taste of this and of other salts of copper is so detestable and so penetrating that if a drop of a solution of one and a half grains of this salt in a pint of water, be placed on the tongue it will have the most disagreeable taste. He called attention also to the fact that the proportion of copper found normally in the liver after a sudden death is much larger than when death has followed a lingering illness, and argued that as the normal figures are still unknown, it would be rash to fix on a maximum cure, above which would be considered proof of accidental or criminal poisoning. M. Rabuteau stated that two or three grains of bichloride of copper dissolved in ℥xxij.-xxx. of water and injected under the skin of a frog caused paralysis of the muscles, especially of those of the hind legs, but that the properties of the sensitive and motor nerves are preserved; death follows in from half an hour to an hour.—*The Lancet*, March 24th, and *Gazette Médicale de Paris*, March 31.

**ALIMENTATION OF INFANTS WHILE SUFFERING FROM INTESTINAL CATARRH.**—Prof. Demme, of Berne, believes that cow's or goat's milk should not be given at all to infants who are suffering from intestinal catarrh. It appears in the passages in the form of agulated, undigested masses. The affection prevents the formation or the normal action of the gastric ferment, and the milk, in traversing the digestive canal, acts as a foreign body, which irritates the mucous membrane, undergoes a putrid fermentation, and causes the continued formation of watery, putrid discharges. As a rule, human milk does not exert these unpleasant effects. Condensed milk is less injurious than cow's milk, although the large quantity of sugar it contains favors fermentation and decomposition. In the Hôpital Jenner, infants affected with acute intestinal catarrh are nourished in the following way:

Twice a day, from a quarter of a pound to a pound of beef is deprived of fat, cut up into fine pieces, infused for an hour in a quart and a half of cold water, and then boiled down to a quarter of its previous

bulk; it is then set aside for a while, the fat skimmed off, and the remainder filtered and set aside to cool completely. It is given cold, in small quantities every two or three hours, and mixed with barley or rice water, which should be prepared first each time by boiling a small quantity of rice or barley in water for a few minutes. When the children are very thirsty, the rice or barley water is given in the intervals without sugar. When they refuse to take the water and bouillon, Prof. Demme resorts at once to albuminous water. This is prepared by beating up the white of one or two eggs, and then adding water in small quantities at a time, while the mixture is being gently stirred. In this way a well mixed fluid is obtained, which is mucilaginous and tasteless, and is readily taken by the children. For infants from one to ten weeks of age, Prof. Demme orders for the bouillon, from a quarter to a half-pound of meat per diem. One, two, or three whites of eggs, according to the age of the patient, suffice for from half a pint to a pint and a half of water, which quantity may be administered daily. When the patients begin to lose strength, he gives from five to thirty drops of the purest cognac from three to five times a day. When in the cases of older children, it is deemed advisable to continue the use of milk, it is diluted with rice or barley water. He has given up the use of grated raw meat in acute intestinal catarrh of infants.

With regard to medicinal treatment, Prof. Demme has found that the profuse serous diarrheas yield readily to very small doses of calomel (gr.  $\frac{1}{20}$  to  $\frac{1}{10}$ ) and opium (gr.  $\frac{1}{10}$  to  $\frac{1}{3}$ ) every two or three hours. Sometimes he has had recourse with advantage to nitrate of silver, with glycerine and a small quantity of opium. He leaves out the opium when possible, because it lessens the strength of the patients. He believes that tannin, bismuth, the vegetable astringents, etc., only irritate the mucous membrane and prolong the affection. The above plan of nourishment is as applicable for the chronic as for the acute form of intestinal catarrh. In the former, Mr. Demme has found the continued use of albuminous water and cognac to be especially valuable.—*Gazette Obstétricale*, April 5, 1877.

**JACCOUD ON THE FECAL ORIGIN OF TYPHOID FEVER.**—As the result of a most exhaustive study of typhoid fever, in which one hundred and six epidemics occurring in different parts of the world were analyzed, M. Jaccoud reaches the conclusion that fecal matters engender the disease, but are not *typhogenic* unless they enclose the specific typhoid poison, which usually comes from the dejections of typhoid patients. There are circumstances, however, under which the fecal matters are poisonous without having had any previous admixture of typhoid matters; in such cases the poison is elaborated in the fecal matters, which themselves are, as before, merely the agents of transmission.—*Journal de Médecine*, May, 1877.

**BELLADONNA IN CONSTIPATION, THE RESULT OF PARALYSIS OF THE BOWELS.**—Dr. H. A. Du Bois, of San Rafael, Cal., writes: "In a case of paralysis of the bowels, the result of apoplexy, where there had been no discharge for two weeks, and where croton oil and other powerful cathartics had failed, and in which the ascending colon only could be emptied by the rectal tube, small doses—five drops three times a day—of the fluid extract of belladonna, continued for two days, enabled the tube to enter the transverse colon, and procured thorough action through the whole length of the canal. I was indebted to Dr. Taylor, U. S. Navy, for this suggestion."

# THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

New York, June 30, 1877.

## THE STATE MEDICAL SOCIETY.

THERE have been so many meetings of State and other medical societies during the past few weeks, that in passing any comments upon them there is much danger of a repetition of ideas. After what we have already said of other organizations of the kind, there would be under many circumstances a temptation to dismiss our own State Society with some commonplace allusions, and with some of the usual complimentary references to a successful meeting, a prosperous body, and a few other set phrases usual on such occasions. But the truth is the meeting has been sufficiently noteworthy to invite independent comment, not only in its own behalf, but on that of other similar organizations which may wish to benefit by its experiences of management and its peculiar method of internal administration. The last session was in every respect a busy one. The programme was very full, and was scrupulously carried out. Indeed, it may not be considered a reflection upon the efforts of the other Presidents to say that more papers were read and more business transacted during the past session than on any previous occasion. This result was in no small degree due to the previous publication of the schedule, to the systematic division of time for the reading of the different papers and for the transaction of other business. The securing of papers beforehand has had a fair trial, and to a certain extent it has succeeded. By this means the time of the meetings has been fully occupied, and the members have had opportunities for preparing themselves for the discussions which were likely to follow the papers announced. So far so good. But there are other difficulties to be considered which are of no small moment in the way of guaranteeing and securing success. There is a great risk of being burdened with useless if not stupid papers. If the President asks indiscriminately for contributions, and accepts them merely on the representations of the authors, there is a possibility that while

he may obtain much that he may desire, there is an equal chance that he may as frequently have forced upon him for the acceptance of the Society papers of very inferior merit. He can hardly restrict his solicitations to men of known ability, as this would be obviously unfair to the other members who may wish to work. Although during the meeting the papers presented were, on the whole, creditable and interesting, there were some concerning which some exceptions should have been made.

We believe that the plan of soliciting papers is a good one and should on general principles be carried out by all large scientific bodies, but we would suggest as a proper safeguard against the abuse of privilege, if not of courtesy, on the part of writers, that the acceptance of said papers should be conditional with the action of a properly appointed Executive Committee. Far from this being the case at Albany, the Business Committee appeared to have nothing to do but to read the order of exercises.

The change in the manner of appointing the Nominating Committee is in every respect a desirable one, and will tend to destroy those ring influences which have in years gone by disturbed the harmony of the rural representations. Heretofore the committee was appointed by the President, and upon his selection depended absolutely the government of the Society from year to year. It is not difficult to see how, with the best of intentions on the part of the appointing power, the ring influences could be indefinitely perpetuated. Now, however, the power is transferred to the members and delegates themselves, who duly elect their representative on the committee, and he is formally named by the President. We fail to imagine how any improvement could be made upon this arrangement, any method of appointment which would be better calculated to suit the majority, or make the organization more thoroughly representative. It effectually removes all trouble connected with the nomination of permanent members, as the matter will be in the hands entirely of those who are best calculated to judge for their particular district.

The change of the time of meeting was a matter which, as the result showed, the Society was hardly prepared to discuss. In fact, no one would have thought seriously of the subject had it not appeared in the programme as a special order of business. We do not think that there was any pressing necessity for a change. Except that the meetings were so near those of the American Medical Association, there was no real objection to the month of June. The argument in favor of meeting during the session of the Legislature amounted practically to nothing, as far as the interests of the Society are concerned. On the other hand, the change to the most inclement month in the year, and at a time when the hotels in Albany are crowded and uncomfortable, will hardly be acceptable to the larger number of members. But the change has been made, and if some of the delegates are snow

bound on the way, they have the consolation of knowing that one way to keep from freezing is to shout, clap hands, and stamp. But even for such as might be willing to run the risk, we presume it would be much more agreeable to them, if not to the Society, to save their breath until they might arrive in Albany. As far as Albany is concerned as a place of meeting, we should prefer the winter to the summer months—in fact, the more inclement the weather the better, as there would be more opportunity for remaining within doors. But as there is no chance, at least for the present, of changing the place of meeting, we must be content and hope for the best.

## Reports of Societies.

### MEDICAL SOCIETY OF THE STATE OF NEW YORK.

*Seventy-First Annual Meeting.*

HELD IN ALBANY, JUNE 19, 20, AND 21, 1877.

TUESDAY, JUNE 19TH.—FIRST DAY.—MORNING SESSION

The Society met, pursuant to statute, in the Assembly Chamber of the Capitol, at Albany, at 11 o'clock A.M., and was called to order by the President, DR. E. R. SQUIBB, of Brooklyn.

The Scriptures were read, and prayer offered by Right Rev. Bishop Doane.

#### INAUGURAL ADDRESS OF THE PRESIDENT.

The President then proceeded to read his opening address, in which he congratulated the members of the Society on its prosperity, and suggested for its still further advancement that the presiding officers be selected with the more single purpose of getting a good active servant of the Society, who would carry out its work with energy; that the presiding officer should carry out and be responsible for the work of the Society at the meeting over which he presided; that the address which usually occupied the Wednesday evening session be discontinued, or at least the penalty of \$25 for failure to deliver it be abolished; that the Secretary's annual salary be increased to \$500, or that the editorship of the Transactions be separated from the duties of the Secretary, and given to an editor; that each volume of the Transactions hereafter should have a copious index; that a list of delegates by counties, with the time of election and expiration of service, should precede the list of permanent members, and be kept up with official accuracy, so that the true character and construction of this body as a society of delegates should be more prominent, and that the Treasurer should receive compensation for the time and labor required of him by the Society.

DR. GRAVES, of Steuben, moved that a vote of thanks be extended to the President for his excellent address, and that it be referred to a committee.

#### ANNOUNCEMENT OF COMMITTEES.

The President announced the following committees: *On Credentials*—Drs. Wm. Manlius Smith, of Onondaga; G. H. Blake, of Livingston; A. L. Saunders, of Madison.

*On Receptions and Arrangements*—Drs. Wm. H. Bailey, E. R. Hun, of Albany; A. W. Tucker, of Washington.

*On Business*—Drs. George Burr, of Broome; S. F. MacFarland, of Chenango; R. H. Ward, of Reusselaer.

*On Ethics*—Drs. Wm. C. Wey, of Chemung; Austin Flint, of New York; Frederick Hyde, of Cortland.

*On Nominations*—Drs. T. F. Rochester, of Erie; A. Hutchins, of Kings; P. R. H. Sawyer, of Westchester; C. E. Witbeck, of Albany; J. M. Rose, of Herkimer; L. A. Van Wagner, of Madison; J. H. Crittenden, of Broome; C. G. Pomeroy, of Wayne.

A recess of fifteen minutes was taken, for the purpose of organizing committees, receiving credentials, and for registration of names of permanent members.

On reconvening, the Committee on Credentials reported a sufficient number of members present to permit the transaction of business.

DR. W. H. BAILEY, Chairman of the Reception Committee, introduced the following delegates from other State Societies; Dr. Collins, of the Massachusetts State Medical Society; Dr. Gillett, of Pennsylvania State Society; and Dr. D. A. Curry, of the New Jersey Society.

The delegates made appropriate responses.

#### MEMBERS BY INVITATION.

On recommendation of the Committee of Arrangements the following gentlemen were made members by invitation: Dr. G. H. Fox, of New York; and Drs. S. B. Ward, John Thompson, J. B. Stonehouse, W. L. Purple, D. H. Cook, and G. H. Newcomb, of Albany.

On motion made by DR. HUTCHINSON, of Brooklyn, the appointment of the Committee upon the President's Address was referred to the Nominating Committee.

#### TREASURER'S REPORT.

The Treasurer reported the balance on hand at the last report was \$287.71; received during the year, \$1,384.31; disbursed during the year, \$1,684.19. In the general fund the receipts were \$1,922.76, and the disbursements \$2,132.31, leaving a balance due Treasurer of \$209.55. The report was referred to an Auditing Committee, consisting of Drs. Ellsworth Eliot, W. Govan, and B. F. Sherman.

The report of the Secretary as Librarian was read and referred to the

#### COMMITTEE OF PUBLICATION.

The report of the Committee on Publication was read and referred to the Committee of Publication for the coming year.

DR. C. S. WOOD, of New York presented a report as delegate to the American Medical Association, which was referred to the Committee of Publication.

DR. H. P. FARNHAM, of New York, presented a like report as delegate to the Massachusetts State Medical Society, and it received a like reference.

DR. BALL, of Kings, made a verbal report as delegate to the New Jersey State Medical Society; and in view of the unusual hospitality shown the delegates from the New York Medical Society, the President requested that the report be submitted in writing and entered upon the minutes.

The Society then adjourned to meet at 3 P.M.

#### FIRST DAY.—AFTERNOON SESSION.

The Society was called to order at 3 P.M. by the President.

DR. ROCHESTER, Chairman of the Committee on Nominations, announced the Committee upon the President's Address, as follows:

Drs. Ellsworth Eliot, of New York; A. Van Derveer, of Albany, and H. Jewett, of Canandaigua.

RECENT IMPROVED METHODS OF DIAGNOSIS AND TREATMENT IN URETHRAL SURGERY, WITH TABULATED STATEMENTS OF RESULTS IN FORTY-FIVE CASES.

DR. R. W. PEASE, of Syracuse, read a paper upon the above subject, which was substantially a support of the views entertained by Dr. F. N. Otis, of New York, regarding the diagnosis and treatment of stricture of the male urethra.

DR. KENDALL, of Baldwinsville, corroborated the experience of Dr. Pease, and Dr. KNEELAND referred to one of Dr. Pease's cases as having been a man who had been under his personal observation.

DR. CASE, of Oneonta, referred to the precaution of using the india-rubber coil for applying cold to the penis, lest unpleasant hemorrhage should occur.

The paper was referred to the Committee of Publication.

FOUR CASES OF SUDDEN DEATH—CORONER'S INQUESTS.

DR. J. KNEELAND, of South Onondaga, reported two cases, as samples, of those which had fallen under his observation as coroner, and in which no cause of death could be found.

DR. ROCHESTER, of Buffalo, referred to cases illustrating, *first*, carelessness on the part of coroners in ascribing death to unknown causes, when very clear cause of death was subsequently ascertained by careful examination, the case being one of murder; *second*, cause assigned by those who were ignorant, hence not reliable, no cause being found by competent observers.

Paper referred to Committee of Publication.

PAPERS READ BY TITLE.

Obituary Notice of Dr. James Thorn, M.D., of Albany. By Dr. R. H. Ward, of Troy.

Biographical Sketch of Dr. A. B. Watkins, M.D., of Troy. By Dr. H. B. Whetton.

Referred to Committee of Publication.

OPERATION FOR CLOSURE OF CLEFT OF HARD PALATE, WITH REPORT OF CASES.

DR. A. VAN DERVEER, of Albany, read a paper upon the above subject, in which he took the ground that the surgeon of the present day could assure the friends of the patient that complete success could be obtained by the operation. Ferguson's operation was recommended, and it was thought best to operate immediately after the first dentition.

DR. GOODWILLIE, of New York, exhibited a wax model of a case upon which he had operated, and described his method of operating.

DR. E. C. HUTCHINSON, of Utica, referred to a modification in the operation which he had practised in one case, namely, the child was placed upon the back, with the head downward over the table, so that the blood ran through the nostrils. He made the mucopariosteal flaps of Langenbeck, and his patient made a good recovery.

The paper was referred to the Committee of Publication.

SANITARY INSPECTION OF SCHOOLS.

DR. WM. C. WEY, of Elmira, read a paper upon the above subject, as a contribution to the report of the Committee on Hygiene. The importance of sanitary inspection in our schools was pointed out in a clear and concise manner.

The paper was referred to the Committee of Publication.

WOOLARA IN THE TREATMENT OF RABIES CANINA.

DR. J. W. GREENE, of New York, sent a communication upon the above subject, in which he recom-

mended the use of this article in the treatment of the disease referred to, and, in addition, suggested the use of ice and dry cupping to the spine.

DR. WEY moved that the communication be referred to the Committee of Publication, with the request that Dr. Greene be requested to complete his paper for publication, giving the Doctor thirty days' limit.

The paper was discussed by Drs. Kneeland and Putnam-Jacobi. Dr. Jacobi argued that, from the physiological action of the drug in question we should not, theoretically, expect much benefit from its use in rabies or any convulsive affection.

THE PRESIDENT remarked that perhaps it might be beneficial in breaking up the habit of convulsion, and in that way assist recovery.

THE FORCEFUL AND RAPID DILATATION OF THE CERVICAL CANAL, FOR THE CURE OF ANTEFLEXION.

DR. H. T. HANKS, of New York, read a paper upon the above subject, in which he set forth the advantages arising from the use of hard rubber bougies in the treatment of anteflexion of the uterus, claiming for the method all that could be obtained by surgical procedure for the cure of dysmenorrhœa and sterility. His instruments have been described in THE RECORD for September of 1875.

DR. JOHN BALL, of Brooklyn, read a paper upon FORCEFUL AND RAPID DILATATION OF THE CERVIX UTERI FOR THE RELIEF OF STRICTURE, CONICAL CERVIX, STERILITY, ETC., ETC.

The paper was properly referred.

The hour of six having arrived, the Society adjourned to meet at 8 P.M.

FIRST DAY.—EVENING SESSION.

The Society was called to order at 8 P.M. by the President.

Credentials and letters were acknowledged from Dr. R. R. Melvaine, of New York, as delegate to the New York State Medical Society from the Ohio State Medical Society.

PUERPERAL METASTATIC IRIDO-CHOROIDITIS.

DR. THOMAS R. POOLEY, of New York, read a paper upon the above subject, in which he reported a case that he had observed in conjunction with Dr. McKenzie, of New York, giving a history of the puerperal disease and the eye affection. The peculiarities of this form of inflammation of the choroid were pointed out, and the theories of its mode of production; and also the differential diagnosis between purulent inflammation of the choroid occurring in cerebro-spinal meningitis and other affections of the brain from that which occurs in septic poisoning of the blood. The paper was referred to the Committee of Publication.

PUNCTURED WOUND OF LUNG, DIAPHRAGM, AND LIVER, WITH RECOVERY.

By DR. S. L. PARMELEE, of Watertown, was the subject of the next paper, and elicited discussion from Drs. Kendall, Chapman, Kneeland, Vosburg, and Gouverneur M. Smith. The discussion related chiefly to the evidence regarding puncture of the liver. The paper was referred to the Committee of Publication.

REPORT OF CASE OF FRACTURE OF THE BASE OF THE SKULL, WITH RECOVERY.

By DR. JOSHUA B. GRAVES, of Corning, gave rise to a protracted and not altogether profitable discussion, which was participated in by Drs. Hyde, Beckett, Chapman, Sawyer, Kneeland, Sherman, and others. The discussion consisted mainly in the relation of re-

markable cases in which recovery had taken place. The paper was referred to the Committee of Publication.

At the hour of 10 P.M. the Society adjourned to meet Wednesday, June 20th, at 9.30 A.M.

THURSDAY, JUNE 20TH.—SECOND DAY.—MORNING SESSION.

The Society was called to order at 9.30 A.M. by the President, and prayer was offered by Rev. Dr. Upson. Minutes of the previous session read, corrected, and approved.

The Business Committee announced the reception of communications from Oneida County, Herkimer County, and Albany County, all of which were referred to the Committee of Publication.

OBITUARY NOTICES.

DR. HARVEY JEWETT, of Canandaigua, read a memoir on the late Dr. George W. Cook, of Canandaigua, who met his tragic death at the hands of an inmate of the asylum over which he was Superintendent.

Obituary of Dr. Gurdon Buck, of New York, was presented by DR. FRED. A. CASTLE, of New York; also obituary of Dr. Henry S. West, who died in Turkey, in Asia, presented by DR. BURR, of Broome County.

All these communications were referred to the Committee of Publication.

The credentials of DR. J. H. POOLEY, as delegate from the Ohio State Medical Society, were presented and referred.

DR. IRA A. RUSSELL, delegate from Massachusetts State Medical Society, was introduced and made an appropriate response.

MEMBERS BY INVITATION.

DR. BAILEY further reported the names of the following gentlemen as members by invitation: Drs. T. K. Perry, C. S. Merrill, Albany; R. H. Sabin, West Troy; G. T. Slevin, Maurice J. Lewi, D. V. O'Leary, E. Van Slyke, and H. March, Albany; H. C. Monroe, Schuylerville; Jas. P. Boyd, Jr., Albany; Fred. D. Lente, Florida; G. L. Ullman, E. B. Tefft, Albany; D. McF. Gouverneur, St. Lawrence County; H. Ogden, of Walton; H. G. Du Bois, Camden; W. S. Jooper, C. E. Nichols, Troy; S. Peters, Cohoes; C. Sawyer, A. Pollard, Essex County; M. Case, Onondaga; J. N. Goff, Cazenovia; Z. Rousseau, Troy; D. H. Goodwillie, New York; Lewis Balch, Albany; J. T. Wheeler, Chatham; A. Ten Eyck, Blooming Grove; Mary Du Bois, Albany; S. Moak, Slingerland; A. Fowler, Wm. Hailes, Wm. H. Murray, Albany.

THE PRESIDENT made a report as delegate to the American Medical Association, and also report as Chairman of the Committee on Pharmacology, accompanied by a resolution relating to the National Medical Museum, all of which was referred to the Committee on Publication.

DR. SQUIBB reported that the American Medical Association had decided that it would not take the subject of the Pharmacopœia into consideration at all, even so far as to hear what might be said upon the subject by its own order, or to make a committee upon it. If the State Medical Societies concurred in that action of their representative body, or failed to protest against or counteract it, they must of course accept the result, whether it be good or bad, upon the materia medica.

Dr. Squibb recommended the subject to the thoughtful attention of every medical man in this State, where the Pharmacopœia practically originated.

NATIONAL MEDICAL MUSEUM AND LIBRARY.

*Resolved*, That the members of the Medical Society of the State of New York should individually endeavor to explain to the members of Congress of their respective localities the nature and importance of this work, to the end that the necessary appropriation for it may not fail through want of knowledge of the character of the work, or mistaken ideas of economy.

REPORT ON BY-LAWS.

DR. WEY, of Elmira, Chairman of the committee, reported the following resolution:

*Resolved*, That the Secretaries of the several county medical societies be and are hereby required to notify the Chairman of the Committee on By-Laws of the Medical Society of the State of New York, within sixty days of the passage hereof, of the approval or rejection of the by-laws, rules, and regulations by the said county medical society, including the date of such approval or rejection, with the name of the officer causing the same to be made; and whether any and what modification or amendments forming such official action have been had in connection with the same.

The object was to obtain concert of action among the medical societies throughout the State.

The report of the committee was adopted.

STATUS OF PERMANENT MEMBERSHIP.

DR. DIMOND, of Cayuga, submitted a communication making inquiry regarding the status of a permanent member of the Society after having been expelled from his county society for non-payment of dues.

Referred to Committee on Ethics.

An obituary notice of Dr. Francis Burdick was submitted by DR. THOMPSON BENTON, and referred to Committee on Publication.

CHANGE OF TIME OF HOLDING ANNUAL MEETING.

After considerable discussion, it was resolved to change the time of holding the annual meeting of the Society to the THIRD TUESDAY OF JANUARY.

DR. CORLISS remarked that he should want a "shingle on the side of his head" to tell him when the State Medical Society held its annual meeting.

DR. JEWETT, from the

COMMITTEE ON THE PRESIDENT'S ADDRESS,

reported that they fully agreed with the President with reference to selecting the best presiding officer. That he should be responsible for the work of the meeting over which he presided, it was thought that the present system was sufficiently simple and satisfactory. With reference to the discontinuance of the annual address, the committee failed to agree with the President. It was thought not to be wise to increase the expenses of the Society by increasing the pay of the Secretary and Treasurer. That the Transactions should have a more complete index was thought advisable. The committee did not recommend the increase of delegation. They believed that the by-laws regulated the formation of certain committees for permanent members, but thought that the Nominating Committee could with propriety be composed of delegates who had served as such the year previous. With reference to the expenses of the Transactions, it was believed that was a matter of business properly belonging to the Committee of Publication.

The report was accepted.

DR. KENDALL, of Onondaga, moved that the report be laid upon the table. Carried.

The paper by DR. J. F. MINER, of Buffalo, on

THE FEASIBILITY OF REMOVAL OF THE THYROID GLAND was referred to the Committee of Publication, and placed at the author's disposal. This reference was made in view of the fact that Dr. Miner was unavoidably absent.

PULMONIC FEVER—GROUNDS FOR CONSIDERING ACUTE PNEUMONIA AN ESSENTIAL FEVER, AND NOT PURELY A LOCAL INFLAMMATION.

DR. AUSTIN FLINT, of New York, read a paper upon the above subject, which will be published in a subsequent number of *THE RECORD*.

The paper gave rise to some discussion, and was referred to the Committee of Publication.

DR. PUTNAM-JACOBI, of New York, then read a paper entitled

TWO CASES OF CONVULSIVE DISEASE WITHOUT CONVULSION.

Both were cases of epileptoid disease—the first a reflex epileptoid seizure—symptomatic of disordered innervation of the solar plexus, analogous to the disorder which ordinarily results in gastralgia; the second a case of psycho-epilepsy, in a family where epilepsy already existed, and hence probably idiopathic. In both cases convulsions were absent, and this fact was held to prove that the vaso-motor nervous system did not affect the medulla. In the first case the attack, which was repeated every ten or fifteen minutes, was ushered in by a painful sensation at the epigastrium, immediately followed by pallor and loss of consciousness, during which of course the pain was abolished. But the morbid impression seemed to persist, and to determine automatic clawing movements of the hands, as if for the purpose of clutching something out. At the same time the child cried incessantly, "Take it out! take it out!" It was argued that these phenomena did not constitute an aura, but indicated a peripheric irritation, which, transmitted by the splanchnic nerves to the vaso-motor nerves of the brain, caused vascular spasms and limited anuria at the cortex—probably localized over the cortical centres for speech and for prehensile movements, which are said to be in close proximity to one another. The abolition of consciousness was explained by increased pressure from collateral rise of tension in the blood-vessels adjoining the anuriated part. In the second case existed only a diminution of intelligence—an "attack of stupidity," or rather an increased resistance to the transmission of mental impressions. This state lasted generally about twenty-four hours. It was interpreted as depending on a paralytic hyperemia, seated, not in the gray matter of the convolutions, but in their communicating fibres.

The paper was referred to the Committee of Publication.

The report of the Special Committee—DR. E. M. MOORE, of Rochester, Chairman—upon the subject of Establishing a Committee to Determine the Qualifications of Students in Medical Colleges, who are about to enter the Profession, the service of such committee to be tendered to such colleges as may desire them, was postponed until the next annual session, on account of the unavoidable absence of the Chairman of the committee.

The Society then adjourned to meet at 3 P. M.

#### SECOND DAY.—AFTERNOON SESSION.

The Society was called to order at 3 P. M. by the President.

The first paper read was by DR. EDWARD H. PARKER, of Poughkeepsie, on

HEREDITY AS A FACTOR IN PAUPERISM AND CRIME.

Dr. Parker took the ground that there was no evidence to establish the doctrine of hereditary tendency to pauperism and crime.

The paper gave rise to some discussion, which was participated in by Drs. Wey, Dimond, and Kneeland, and then referred to the Committee of Publication.

DR. KENDALL, of Onondaga, called up the report of the Committee on the President's Address, and moved to recommit that portion relating to the formation of the Nominating Committee, with instructions to amend as follows:

*Resolved*, That sec. 11 of chap. 3 of the by-laws be amended so as to read as follows:

At the annual meeting, immediately after the adjournment of the first session, the permanent members and delegates present from each Senatorial District of 1836 shall be constituted a committee, which shall elect one of their own number and from their own district, who shall be a member of the Nominating Committee, and the eight persons thus elected shall constitute a Committee of Nomination.

The motion was carried.

DR. KNEELAND, of Onondaga, moved to recommit that portion of the report relating to the President's annual address, with instructions to report in favor of adopting the recommendation offered by Dr. Squibb in his inaugural—namely, to discharge the President from the delivery of an annual address. The motion was lost.

The report was then adopted, with the exception of the portion recommitted.

TREASURER'S REPORT—NON-PAYMENT OF DUES.

The Committee on the Treasurer's Report, after referring to the correctness of the report of that officer, reported that a permanent member shall not be permitted to register until his dues shall have been paid. In regard to county societies and colleges it was recommended that their delegates should not be permitted to register until the dues against the organizations which they represented shall have been paid. The report was adopted.

STONES IN THE BLADDER.

DR. J. W. S. GOUTLEY, of New York, read a paper upon the above subject, which was referred to the Committee of Publication. An abstract of the paper will appear in a subsequent number of *THE RECORD*.

NITRITE OF AMYL IN PERTUSSIS.

DR. GEORGE BAYLES, of New York, read a paper upon the above subject, in which he considered the beneficial influence arising from the use of amyl nitrite in the treatment of whooping-cough, and reported several cases. The drug was administered in from one to three minim doses and repeated every two, three, or four hours, according to age of child and urgency of symptoms. No antagonism existed between the remedy and quinine. Quinine was administered in most of Dr. Bayles's cases prior to the use of amyl. It was regarded as a safe remedy when used properly, and one of more than ordinary value in the treatment of the affections to which special reference was made. It was regarded as specially adapted to the treatment of spasmodic affections and for breaking up the habit of such diseases.

THE COLD BATH IN SCARLATINA.

DR. C. H. GIBERSON, of Brooklyn, read clinica

notes showing the favorable results attending the use of cold baths in the treatment of scarlet fever. The report presented evidence of careful preparation. We should not permit temperature to rise above 102 F., should use water from 100° to 70 F., and continue the bath just long enough to reduce temperature to 100 F.

The paper was discussed by Drs. Putnam-Jacobi, Douglas, and Kneeland, and referred to the Committee on Publication.

#### JABORANDI.

DR. A. HUTCHINS read a paper upon Jaborandi, in which he spoke of the remedy as one of value for the relief of symptoms common to many diseases. The effect of the drug was especially diaphoretic.

The paper was properly referred.

#### VAGINAL INJECTIONS.

DR. FRANK P. FOSTER, of New York, read a portion of a paper upon the above subject. It was referred to the Committee of Publication.

#### SOME OF THE MORBID CONDITIONS OF THE PROSTATE GLAND.

DR. FREDERICK HYDE, of Cortland, gave an abstract of his paper upon the subject, and urged the early use of the catheter, and the retention of the instrument rather than to remove and reinsert; it might be worn three or four days without removal. The paper was referred to the Committee of Publication.

The Committee on the President's Address reported in regard to the portion of their former report which was recommitted, that they could not agree, and submitted the question to the action of the Society.

The report was laid upon the table.

The Society then adjourned to meet at 8 P.M.

#### SECOND DAY.—EVENING SESSION.

The Society was called to order at 8 P.M., by the President.

The first order of business was the

#### REPORT OF THE COMMITTEE ON HYGIENE.

DR. A. N. BELL, of Brooklyn, Chairman, reported in abstract. Reports had been received from the counties of New York, Westchester, Kings, and Putnam. Special reports had been received from Dr. Wey, of Elmira, and Dr. Stoddard, of Rochester.

#### PSEUDO-MEMBRANOUS LARYNGITIS — TRACHEOTOMY — RELAPSE AND RECOVERY.

DR. NORMAN L. SNOW, of Albany, related the history of a case, the outlines of which are embraced in the title. Durham's tracheotomy tube was recommended. The patient was fifteen months of age.

#### TAR FUMIGATION IN GANGRENOUS SORES.

The paper was submitted by Dr. LEWIS POST, of Lodi, Seneca Co., and was read by the President.

The sore treated by Dr. Post was located upon one of the lower extremities; it resisted all ordinary remedies, but finally yielded to fumigations with tar. The hagedenic appearance was changed entirely within one week. The fumigation was continued for only about three minutes at each sitting, and repeated according to circumstances. Dr. Post thought it possible that he had inhaled the toxic miasm from those sores, and that that was the cause of the sickness, a laryngeal trouble, from which he had suffered since the treatment of his patient.

#### HYDROCHLORATE OF AMMONIA—AMMONIÆ MURIAS.

DR. C. G. POMEROY, of Wayne, gave an interesting

*résumé* of the history of this article, and followed with a reference to its special value in the treatment of affections of the mucous membrane of the air-passages, particularly when accompanied with the formation of thick tenacious secretion.

Ordinary inflammation of the throat and lungs, and catarrhal croup, were uniformly treated by the use of the remedy. Its use in the treatment of swollen and ulcerated lymphatic glands, and also psoriasis and eczema, facial neuralgia, and several other affections, received favorable mention.

The paper was referred to the Committee on Publication.

#### CERTAIN POINTS RELATING TO THE NATURE AND TREATMENT OF LUPUS.

DR. H. G. PIFFARD, of New York, read a paper upon the above subject, which will appear in a subsequent number of THE RECORD.

On motion, made by DR. KENDALL, the report of the Committee on the President's Address was taken from the table, and, after considerable discussion, the proposed amendment to the by-laws adopted by a vote of 45 to 16.

The Nominating Committee at the next Annual Meetings will not be appointed by the President, unless further action shall be taken by the Society.

The paper on

#### HEREDITARY TRANSMISSION OF DISEASE.

by DR. IRA F. HARTT, of Elmira, was submitted and referred to the Committee of Publication.

The Society then adjourned to meet at 9.30 A.M., June 21.

#### THURSDAY, JUNE 21ST.—THIRD DAY—MORNING SESSION.

The Society was called to order at 9.30 A.M. by the President.

Prayer was offered by Rev. Dr. McBlaney. Minutes of previous day read and approved.

DR. SMITH, Chairman of the

#### COMMITTEE ON CREDENTIALS.

reported that 200 names had been registered.

DR. WEY, Chairman of

#### COMMITTEE ON BY-LAWS,

reported that the fact of a permanent member of the State Medical Society having been expelled from a county medical society for

#### NON-PAYMENT OF DUES

did not affect his standing in the State Medical Society, until such Society had been officially notified of such delinquency. Adopted.

The Chairman further reported that suspension or withdrawal from a county medical society was fatal to an admission to the State Medical Society, but that it did not disturb the membership of a permanent member. Adopted.

DR. BURR, Chairman of the

#### BUSINESS COMMITTEE,

announced the reception of a communication from DR. A. O. KELLOGG, of Dutchess County, which was referred to the Committee on Publication.

DR. B. F. SHERMAN, Censor to the University at Syracuse, made a report which took a like reference.

#### REPORT OF THE COMMITTEE ON NOMINATIONS.

DR. A. HUTCHINS, of Brooklyn, Secretary of the committee, reported as follows:

For President—Dr. J. Foster Jenkins, of Yonkers.

*For Vice-President*—Dr. Augustus L. Saunders, of Brookfield.

*For Secretary*—Dr. Wm. Manlius Smith, of Manlius.

*For Treasurer*—Dr. Chas. H. Porter, of Albany.

*For Censors*—Southern District, Drs. E. R. Peaslee, New York; E. H. Parker, Poughkeepsie; E. Eliot, New York. Eastern District, Drs. A. B. Whiton, Troy; James L. Babcock, Albany; J. I. Shaver, Little Falls. Middle District, Drs. M. M. Bagg, Utica; G. W. Cooke, Otego; C. G. Bacon, Fulton. Western District, Drs. C. C. Wyckoff, Buffalo; H. Jewett, Canandaigua; C. Green, Homer.

*Committee on Correspondence*—1st District, Drs. T. Addis Emmet, New York; 2d, W. I. Townsend, Goshen; 3d, W. S. Seymour, Troy; 4th, T. B. Reynolds, Saratoga; 5th, S. G. Wolcott, Utica; 6th, J. G. Orton, Binghamton; 7th, A. B. Wilbur, Syracuse; 8th, C. E. Rider, Rochester.

*Permanent Members*—Drs. J. S. Prout, B. A. Segur, Kings; A. E. M. Purdy, Wm. Chamberlain, New York; T. Hammond, Dutchess; J. F. Chapman, Westchester; H. March, Chas. A. Robertson, Albany; J. M. Rose, Herkimer; A. Pollard, Essex; W. Taylor, Madison; N. J. Barnett, Oswego; L. J. Ames, Livingston; J. Wiley, Steuben; A. F. Sheldon, Wayne; A. R. Otis, Yates; G. Swinburne, Monroe; J. C. Green, Erie.

*Honorary Members*—Drs. Samuel C. Busey, of Washington, D. C.; W. A. F. Brown, of Dumfries, Scotland; S. Weir Mitchell, of Philadelphia, Pa.; Wm. S. Hopkins, of Vergennes, Vt.; Louis Wecker, of Paris, France.

*Eligible to Honorary Membership*—Drs. Clarkson T. Collins, of Great Barrington, Mass.; Joseph B. Brown, U. S. A.

#### DELEGATES.

*To the Pennsylvania State Medical Society*—Drs. S. Shove, of Westchester; Wm. C. Wey, of Chemung.

*To the Massachusetts State Medical Society*—Drs. P. R. H. Sawyer, Westchester; J. L. Banks and H. S. Farnham, New York; J. Bates, Columbia; J. F. Miller, Erie.

*To the Connecticut State Medical Society*—Drs. A. Hutchins, Kings; L. Cross, Schoharie; G. S. Wolcott, Oneida.

*To the New Jersey State Medical Society*—Drs. J. C. Hutchinson, Kings; H. D. Noyes, New York; R. H. Ward, Rensselaer.

*To the New Hampshire State Medical Society*—Drs. W. Govan, Rockland; L. D. Bulkley, New York.

*To the Vermont State Medical Society*—Dr. E. F. Edgerly, Essex.

*To the Rhode Island State Medical Society*—Dr. C. M. Allin, New York.

*To the Canadian Medical Society*—Drs. E. D. Ferguson, Clinton; B. F. Sherman, St. Lawrence; H. G. P. Spencer, Jefferson.

*To the Iowa State Medical Society*—Dr. J. Kneeland, Onondaga.

*Censor of the Syracuse University*—Dr. Wm. H. Bailey, of Albany.

#### COMMITTEES.

*On Prize Essay*—Drs. A. W. Dean, Monroe; J. F. Miner, Erie; W. S. Ely, Monroe.

*On By-laws*—Drs. W. C. Wey, Chemung; W. M. Smith, Onondaga; Wm. H. Bailey, Albany.

*On Publication*—Drs. R. M. Wyckoff and E. R. Squibb, Kings; W. M. Smith, Onondaga; Chas. H. Porter, Albany.

*Hygiene*—Drs. E. V. Stoddard, Monroe; C. R. Agnew, New York; J. G. Orton, Broome; J. C.

Hutchinson, Rensselaer; E. M. Lyon, Clinton; E. Hutchinson, Oneida; H. Jewett, Ontario.

On motion, the Secretary deposited a ballot in the affirmative for President, Vice-President, Secretary, and Treasurer, who were duly declared elected.

The remainder of the report was adopted by a *viva voce* vote.

The delegates to the American Medical Association are to be elected at the annual meeting in January, 1878.

DR. WEY introduced the following resolution:

*Resolved*, That the President be directed to appoint a member to codify the by-laws of this Society from 1849, the date of the last publication of the same, to and including the present session, with authority to print one thousand copies.

Adopted.

THE PRESIDENT appointed Dr. A. Hutchins, of Kings County, as such committee.

#### COMMITTEE ON PRIZE ESSAY.

THE CHAIRMAN of the committee, through the President, reported that no essay had been presented, and that there were no funds with which to pay a prize.

On motion made by Dr. Burr, the report was accepted, and the President remarked that it seemed hardly worth while to adopt it.

#### PRIZE ESSAY FOR LAST YEAR.

Considerable discussion ensued on a proposition to pay Dr. A. Hutchins the sum of \$100 for his essay presented last year, and it was finally resolved to pay the amount from the treasury of the Society.

At this point in the business transactions,

DR. HIRAM COLLINS arose, and was granted the privilege of making a few remarks. After alluding to the change of time for holding the annual meeting, in a voice trembling with emotion, he bade the Society an everlasting fare-well. The inclemency of the winter season would preclude all possibility of his attendance upon another annual meeting.

#### REPORT OF THE COMMITTEE OF ARRANGEMENTS.

DR. WM. H. BAILEY, Chairman, recommended the election of the following gentlemen as

#### MEMBERS BY INVITATION.

Alexander Ennis, Pattersonville; E. W. Carmichael, Sand Lake; Robt. J. Bullock, Albany; Nicholas H. Freeland, Tarrytown; G. P. Salmon, Hudson; O. D. Ball, Albany; J. Denham Palmer, Fernandina, Florida; P. C. Neher, Nassau; A. T. Van Vranken, West Troy; J. W. Moore, Cohoes; R. H. Starkweather, Albany; G. H. Armsby, Albany; J. C. Healey, Albany; Willis G. Tucker, Albany; R. D. Traver, Troy; S. A. Russell, Albany; Wallace Clark, Utica.

#### PAYMENT OF OLD DEBTS.

On motion, it was resolved to pay a bill which had been sent to Dr. J. W. S. Gouley, of New York, for extra printing, and also to refund to Dr. Little, of New York, the amount which he had paid for extra printing under similar circumstances.

The *extra* related to illustrations accompanying the papers formerly presented by these gentlemen, and printed in the Transactions.

There being no further miscellaneous business, the Society returned to the hearing of papers.

#### HEMOPHILIA.

DR. JAS. C. HUTCHINSON, of Troy, read a brief paper upon this subject, using the term as one synonymous with hemorrhagic diathesis.

It was discussed by Dr. Sherman, and referred to Committee of Publication.

Telegram from A. JACOBI, of New York, excusing his absence, and expecting to be able to be present and do his duty at the next annual meeting.

#### EXPERIENCE IN SHOULDER AND ARM PRESENTATIONS.

DR. ISRAEL PARSONS, of Marcellus, read a paper upon the subject announced, and reported cases. The Doctor's method consisted essentially in pushing the presenting part up, and thereby changing the case into one of vertex presentation.

The paper was discussed by Drs. W. Manlius Smith, Lyman, and Kneeland, and referred to the Committee of Publication.

#### CASES OF WOUNDS OF THE SYNOVIAL MEMBRANE OF THE KNEE-JOINT SUCCESSFULLY TREATED WITHOUT ANTISEPTIC APPLICATION.

DR. GEORGE BURR, of Binghamton, gave the history of a case in which a floating cartilage was removed from the joint mentioned. The limb was dressed, placed in a box, and kept perfectly quiet, and the patient recovered without unfavorable symptoms, and without check towards restorative processes. If this and another case of like character had been treated by the method of Lister, such favorable recovery would probably have been attributed to the antiseptic method.

The paper was discussed by DR. HUTCHINSON, of Brooklyn, who was inclined to regard Dr. Burr's cases as exceptional, and not as evidence against the value of the antiseptic method of Lister.

The paper was referred to the Committee of Publication.

#### ACTION OF MERCURY.

DR. H. N. EASTMAN, of Owego, was emboldened to read a paper upon the action of a familiar drug, and believed that it exercised its influence in one of three ways:

1. By stimulating the capillary vessels.
2. By eliminating products into the intestinal canal; and
3. By working certain changes in the blood.

The Doctor was not prepared to accept the view that mercury did not stimulate the liver.

The paper was referred without discussion.

#### OPIMUM INEBRIETY AND THE HYPODERMIC SYRINGE.

DR. S. F. McFARLAND, of Oxford, entered his protest against the indiscriminate use of the hypodermic syringe in administering opium, and especially against placing the instrument in the hands of the patient, unless under the most peculiar and urgent circumstances.

The paper was discussed by Drs. Parsons, Kendall, and Beckett, and referred to the Committee on Publication.

The following papers were read by title and referred:

- On Lumbago, by Dr. Peters, of Cohoes.
- Fatty Embolism, by Dr. Wm. H. Bailey, of Albany.
- Fracture of the Base of the Skull, by P. R. H. Sawyer, of Bedford.
- Typhoid Infection of Drinking Water, by E. V. Stoddard, of Rochester.

DR. A. HUTCHINS, of Kings, addressing the Vice-President, moved that a vote of thanks be tendered to the President for the dignity, patience, and enthusiasm with which he had presided over the deliberations of the Society. Unanimously carried.

Dr. Squibb accepted the thanks, and remarked that

it gave him pleasure to transfer the larger portion of them to the committees and officers, whom he was sure were embraced within the intentions of the motion.

A motion to adjourn being made and carried, the President declared the seventy-first annual meeting of the Medical Society of the State of New York adjourned to meet in Albany at 11 o'clock on the third Tuesday of January, 1878.

## Correspondence.

### REOPENING OF THE NEW YORK HOSPITAL.

By GOUVERNEUR M. SMITH, M.D.,

ONE OF THE ATTENDING PHYSICIANS.

THE MEDICAL RECORD of March 24, 1877, announced the reopening of the New York Hospital on March 16th, in its new building extending from Fifteenth Street to Sixteenth Street, a few feet west of Fifth Avenue. The site of the hospital, though near the fashionable thoroughfare of the metropolis, and adjoining the residences of the opulent, is doubtless destined shortly to be the centre of vast commercial interests, judging from the changes already apparent in the adjacent Union Square, and from the large amount of capital expended in the palatial warehouses of the neighborhood.

The hospital will consequently provide for the accidents incident to trade and to factories in its section of the city, while at the same time providing for the lower part of the town in its branch establishment, near its former locality.

The institution is popularly designated as the "Old New York Hospital." Ten decades of years is not a long period of time, but our Republic has only just celebrated its centennial birth-year, and is perhaps justified in regarding as old the institutions which are contemporaneous with its history.

Early records inform us that several benevolent people of this island, in 1770, subscribed towards the establishment of the hospital, and that Drs. John Jones, Samuel Bard, and Peter Middleton presented a petition to Lieut.-Gov. Colden for a charter of incorporation. In 1771 the charter was granted by the Earl of Dunsmore, Governor and Commander-in-Chief of the Province. It should not be forgotten, in this connection, that while the mother country, about this time, was sadly misbehaving toward her American colonies, that many philanthropic persons in London and Great Britain contributed to the funds of the hospital, chiefly through the exertions of two distinguished English physicians, viz., Dr. John Fothergill and Sir William Duncan.

It is highly interesting to read the biographical sketches of those humane and skilful physicians and patriotic citizens, Drs. Jones, Bard, and Middleton. Dr. Jones despised titles and judged mankind from their inherent qualities. He was so democratic in his feelings, indeed, that he thereby incurred at one time the displeasure of his professional brethren.

The subjoined incident concerning him, as illustrating this fact, has been recorded in his life: "At an early date of Dr. Jones's settlement in New York, some of the physicians entered into a resolution to distinguish themselves from the rest of their fellow-citizens by a particular mode of wearing their hair; and among the rest it was proposed to Dr. Jones." Dr. J. would not enter into any such agreement, declaring it

to be beneath the dignity of the medical profession to attract attention and impose upon the weakness and credulity of others. "While the rest of the practitioners, therefore, were seen strutting about in their new-fashioned bob, Dr. Jones could not be distinguished from any well-bred gentleman of another profession. It might be naturally supposed that the persons who were weak enough to enter into the resolution would likewise be capable of the low passion of envy, and seek for a proper occasion of revenge upon those who should dissent. This was actually the case in the present instance, for the consequence of Dr. Jones's refusal to adopt the plan was an agreement not to consult with him. This resolution, however, was of but little avail, for one of the associates, on expressing this determination to a respectable citizen in whose sick-room they happened to meet, was, to his great mortification, unexpectedly dismissed, and Dr. Jones was retained. So effectually did the disclosure of the scene operate, and so general was the ridicule which followed, that the object of the association was entirely defeated, and the members were under the necessity of wearing their hair like the rest of their fellow-citizens."

Dr. Bard likewise was a man of sterling character. The following quotation from a letter addressed to his son, just completing his legal studies, illustrates his qualities: "Be open, my dear boy, to conviction; but never suffer yourself to be led in opposition to your own judgment, unless in the case of friends whose age and experience qualify, and whose relationship authorizes them to give you advice. Never become the hanger-on of a party, nor suffer yourself to be carried beyond the bounds of sober judgment when measures are the subject of dispute; nor of candor and moderation when men are; but on all occasions endeavor to think for yourself and support independence both in your conduct and opinions."

It was men of such description who helped to mould the hospital, and who imparted an independence, a tone, and a dignity to the medical profession of their time—qualities still observed among the estimable physicians of the present day. The successful and indeed brilliant history of the hospital is so well known that it is unnecessary to here review it. Suffice it to say, that from its incipency its governors have been gentlemen who, from their commercial enterprise, have largely contributed toward giving New York its metropolitan character, who have been zealous in promoting the interests of the hospital, and who from their personal virtues have gained both private and public esteem. The medical staff has always been pre-eminent, and no other institution of its kind in the world can exhibit more beautiful examples of the union of integrity, of humanity, and of skill, than has been shown in the lives of the physicians and surgeons of the hospital.

In 1869, owing to financial reasons, the institution temporarily suspended its general operations. Though rich in landed estate the property was unproductive of income. This difficulty has been partially obviated, and with the means now at the command of the governors, the spacious and elegantly appointed hospital recently erected, it is believed, can be efficiently conducted. As its revenues increase, as they necessarily must do, the society will doubtless be enabled to carry on benevolent work in a manner eclipsing its former capabilities.

On the evening of March 16, 1877, after the address by Dr. William H. Van Buren, at Chickering Hall, the hospital was formally opened and inspected by a large number of invited guests. On the following day the

building was ready for occupancy. The Committee of the Board of Governors, viz., Messrs. James W. Beckman, Jackson S. Schultz, William B. Hoffman, Sheppard Gandy, D. Colden Murray, and William H. Macy, were on the alert, giving heed to every necessary detail to insure efficient operation. Dr. Francis M. Weld, medical superintendent, was actively engaged in co-ordinating the various departments of the institution. Dr. Charles H. Knight, resident physician and surgeon, with his two assistants, Drs. Holt C. Wilson and S. S. Kahn, were ready to attend to their respective and important duties to the sick and injured.

On March 17th the first surgical case was received, and on March 19th the first medical case was admitted. The grand machinery of a noble charity again began to move—no rest before it in summer or in winter, by night or by day, on holy day or holiday. Constant labor, eternal vigil, the prices of success.

In the arrangement of the Medical Board for services during the ensuing year the first surgical service, extending from March 17th to June 1st, devolved upon Dr. Charles M. Allin, and the first medical service, extending over the same period, devolved upon myself. During this term 180 patients were admitted to the hospital, 78 of these being medical and 102 being surgical.

Already the wards and operating theatre have become familiar with sights of human suffering and echoed expressions of anguish. Already disease has been relieved by means, now ordinary, which would have astonished our medical forefathers, and appliances have been employed for the relief of injuries which would have amazed the old and veteran surgeons. Already within the walls of the hospital the first inspiration of life has been breathed and the last expiration has been taken. To those suffering with mortal disorders the kindly word has been spoken, the cordial food, draught, and medicine have been administered, and wishes have been gratified by thoughtful and efficient attendants. Thus have they enjoyed a peaceful euthanasia, which for persons in their circumstances of life could scarcely have been hoped for, excepting in some sister benevolent institution.

The hospital, as is seen, has fairly entered upon its benign work. From its metropolitan character and central location it will doubtless attract a large proportion of cases of the greatest gravity. Judging alike from the class of patients admitted to the Chambers Street branch, and from a number of the cases brought to the hospital, it would seem probable that one of the most important provisions of the infirmary will be for maladies and injuries of severe forms. To say nothing of the accidents constantly liable to occur, there are always in the community a number of persons predisposed to apoplexy, many suffering with organic diseases, especially of the heart and blood-vessels, of the lungs, kidneys, etc., who, though able to attend to certain duties of life, are liable at any moment to be overcome and to be carried for immediate succor to a hospital.

Humanity demands of our civil authorities that the city shall be districted in such a manner that cases of severe accidents and sudden disease shall be sent to the nearest desirable hospital, unless friends of such patients can provide readily accessible private accommodation for them. The hospital is connected by telegraph with police headquarters, and is provided with an ambulance, ready at all hours, for immediate use.

The attention of the medical profession is specially called to the extensive library of the hospital, which

is open daily for consultation without expense to the visitor. The governors make a liberal annual appropriation for its increase, and here those engaged in studying the various departments of medical science can, by the aid of the accomplished librarian, Dr. John L. Vandervoort, find a rich field of research.

The pathological museum, under the care of Dr. Christopher M. Bell, is worthy of particular notice. Under the management of this cultured pathologist and of his predecessor, the late Dr. Robert Ray, Jr., the museum has become attractive and instructive, and, indeed, is unique in the beauty of its appearance.

For about three-quarters of a century the New York Hospital was an institution *sui generis* in this city. With the growth of the metropolis kindred institutions sprang into existence, and though several of them are under sectarian management, they are carried on upon catholic principles, neither the nativity nor the creed of a sufferer being a hindrance to admission to their wards. Such infirmaries are the outgrowth of an advanced Christian civilization. It is more than probable that many a forlorn patient, in finding comfort within their welcome walls, has been led for the first time to chant those old words of Stephen of St. Sabas:

"Art thou weary? art thou languid?  
Art thou sore distressed?  
'Come to me,' saith One, 'and coming,  
Be at rest!'"

Never before in the history of our country have the managers of our numerous and diverse benevolent institutions had such a difficult task before them as at the present moment. The benevolence of the American people has been so generous, nay, so prodigal, that it has fostered pauperism. A large number of able-bodied adult paupers are supported by communities, and children are trained by these paupers in the school of beggary. An army of "tramps" secure food, raiment, and lodging, and when sick or injured receive a similar kind care to that paid by the Samaritan to the man who fell among thieves as he went down from Jerusalem to Jericho. At the present day the everlasting cry of "backsheesh" disturbs the traveler in lands around which cluster sacred memories. The proud old Italian cities swarm with mendicants—the densely-populated countries of the old world are thronged with beggars.

In our land there is no cause for general indigence. Our immense territory cannot be overcrowded for centuries, and its agricultural and mineral resources promise the laborer full reward. The government offers liberal inducements to settlers on its domain, while railroad companies offer for sale, at mere nominal rates, vast regions of fertile soil upon their borders. Patriotic citizens should unite in eradicating beggary from our midst before it assumes more gigantic and irremediable proportions. The demand of agrants for food must be met by the response: "In the sweat of thy face shalt thou eat bread."

Sickness and disaster, however, must often induce overtury among deserving persons. The poor will always be with us; such deserve pity, such will gladly be aided, and, indeed, daily betriended. Of all our charitable institutions, the hospitals are least likely to be abused. Let the benevolent rejoice at the reopening of the old New York Hospital, and wish it success as well as its kindred infirmaries roughout the city and throughout the land.

ALBANY MEDICAL COLLEGE.—The Faculty of the Albany Medical College have bought the institution on that city.

## THE CONNECTION BETWEEN CHOREA AND ERRORS OF REFRACTION OF THE EYE.

TO THE EDITOR OF THE MEDICAL RECORD.

THERE appears in THE MEDICAL RECORD of June 2d, an address with the above title, in which the author discusses the proposition announced by myself that "chorea is a functional disturbance of the nervous system which may give rise to organic lesions, and which arises from irritation dependent upon anomalous refraction of the eye, and in a large proportion of cases upon hypermetropia."

The author cites thirty-one cases of chorea observed by himself, and in which, he informs his readers, he has carefully tested the refractive condition of the eyes.

He lays down certain rules for procedure in such cases which are certainly good, indeed, indispensable to a correct understanding of the relations discussed.

As the result of these examinations we are informed that of the thirty-one cases, sixteen have hypermetropia, and fifteen are emmetropic; that is, free from refractive errors.

If the question of the relation of the nervous trouble to the refractive conditions of the eye is worth investigating, the method of proving by accurate examinations of cases is surely the true one, for it matters little how much we may discuss the general principles involved, we must, after all, resort to the ultimate test of facts, and from this test there can be no appeal. In this view of the case the facts presented in this paper would certainly not appear to sustain the proposition which I have made; but inasmuch as I have supported that proposition by forty-one cases published in connection with it, there would seem to be a conflict of facts or a want of thorough accuracy on the part of one of the observers. For it could scarcely happen, if both series of tests have been made with an equal degree of precision, that I should have found forty-two successive cases in which important refractive errors were coincident with chorea, while Dr. Bull, in similar circumstances, finds but sixteen such coincidences among thirty-one cases. Hence one or the other of these two series of assumed facts must be deemed unreliable.

In my own series of cases I have been careful, by giving the initials of patients and the names of physicians through whose kindness I was enabled to examine them, to so identify many of them as to enable any one interested to revise my work. In other cases, I shall be glad to afford my medical friends any assistance within my power in making such revision.

Let us now inquire whether the cases reported by Dr. Bull will bear inspection. It will be conceded that it is extremely difficult, not to say unpleasant, to question facts presented by a respectable authority, and unless there is intrinsic evidence of a want of scientific accuracy in the report of cases, there would seem to be no ground for a public dissent from the assumed facts.

Is there, then, in the cases reported by the author of the paper intrinsic evidence of a disregard of scientific accuracy in his report of these cases? If so, and if such disregard can be shown in a considerable number of instances, we are at liberty to regard his whole series of assumed facts as unreliable.

Dr. Bull reports the following:

"Case XXVII.—Boy, *æt.* three and a half; . . . . . After atropia, *emmetropia*, though examination somewhat difficult, owing to restlessness."

The age of this infant of course precludes the idea

of any examination having been made by trial-glasses or optometer, and the refraction must have been determined by the ophthalmoscope. Does Dr. Bull claim that by the flash of his mirror he is able to declare the absence of any refractive error in this restless babe? This would indeed be a remarkable achievement. It is true that ophthalmologists are accustomed in their daily practice to make by the ophthalmoscope approximate determinations of refractive conditions, especially in cases of gross refractive errors, and it is true also that in the hands of the most expert, and under the most favorable circumstances conceivable, even low degrees of astigmatism may be determined by this method, but it will be hard for Dr. Bull to convince ophthalmologists of experience that he has or can determine emmetropia in this infant.

But this is not the only case in which the author claims to have attained results which, in the nature of things, must be extremely doubtful. In the examination of at least twelve eyes reported in this paper, the circumstances of the cases render it extremely improbable, not to say impossible, for reasons above stated, that he should have determined emmetropia, as he claims to have done. Nor are these the only cases reported, upon which grave suspicion as to scientific accuracy must rest; but surely these are sufficient to render it certain that in this series of cases the methods of observation have been extremely loose and unreliable.

There is, however, one portion of the paper in question which merits attention. In the "Martin" family are eight living children; of these four are stated to be hypermetropic, and four emmetropic. Is it not a striking fact that of the four hypermetrops *three* have chorea, while no chorea is found among the four emmetrops?

We are told that in five of the cases observed glasses for the correction of the refractive errors were prescribed and worn without benefit, so far as the nervous trouble was concerned. I have no means of accounting for the failure in these cases; but against these failures allow me to place the following success:

E. P., aged fourteen, had her first attack of chorea, a very severe one, in the autumn of 1873; no apparent cause. The more violent symptoms subsided after two months, and the disease assumed a chronic form. In May following she had obstinate interstitial keratitis for which, during two months, she was treated by a distinguished ophthalmologist, who observed her distressing nervous condition, and also the fact that she had astigmatism; but did not trace any connection between the neurosis and the refractive error. Under the use of atropia, iron, and cod-liver oil, the corneal trouble disappeared, but after a few months the neurosis manifested itself more violently than ever. She was placed in charge of several distinguished medical gentlemen, successively, but with little improvement in her condition. From that time until when I first saw her, in October, 1876, she had not been free from chorea. Her speech was exceedingly defective, her gait irregular, her extremities in constant motion. During three years she had been deprived of schooling, but when I saw her had just been placed in a boarding school, not to study, but in the hope that she might derive intellectual benefit from being in the presence of students and teachers. I found: Sight, right eye,  $\frac{7}{100}$ ; left,  $\frac{1}{10}$ . In each eye was found a high degree of astigmatism, which, being corrected by glasses, sight was raised to  $\frac{10}{100}$  in right and  $\frac{10}{100}$  in left. Glasses were prescribed and worn, and when I saw her two months later I could detect no indication of chorea, and she assured me that she had wonderfully improved in her nervous condition and was quite able to

go on with her studies. No medicines were given, and she attributed her cure entirely to her glasses.

At my convenience I shall report many other cases of chorea already observed, of which the above is by no means the most striking or interesting.

Geo. T. Stevens.

ARMY NEWS.

*Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from June 17 to June 23, 1877.*

HEAD, J. F., Surgeon and Medical Director. Granted leave of absence for one month. S. O. 121, Dept. of the South, June 16, 1877; and leave extended one month. S. O. 135, Div. of the Atlantic, June 21, 1877.

GRAY, C. C., Surgeon. Assigned to duty at Fort Riley, Kan. S. O. 115, Dept. of the Missouri, June 16, 1877.

FRYER, B. E., Surgeon. Granted leave of absence for 15 days. S. O. 116, Dept. of the Missouri, June 18, 1877.

WOLVERTON, W. D., Surgeon. When relieved by Asst. Surgeon MAUS, assigned to duty at Fort A. Lincoln, D. T. S. O. 77, C. S., Dept. of Dakota.

WHITEHEAD, W. E., Asst. Surgeon. Assigned to duty at Fort Learned, Kan. S. O. 115, C. S., Dept. of the Missouri.

MAUS, L. M., Asst. Surgeon. Assigned to duty at Standing Rock Agency, D. T. S. O. 77, C. S., Dept. of Dakota.

TORNEY, J. H., Asst. Surgeon. Relieved from duty in Dept. of the Gulf, and to report in person to the Com'd'g General, Dept. of the Missouri, for assignment to duty. S. O. 135, A. G. O., June 15, 1877.

Medical Items and News.

CONTAGIOUS DISEASES.—Comparative statement of cases of Contagious Disease reported to the Sanitary Bureau, Health Department, for the two weeks ending June 23, 1877.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-Spinal Meningitis.	Measles.	Diphtheria.	Small-pox.

ABUSE OF MEDICAL CHARITIES.—The British medical press complains bitterly of the growing abuse of medical charity. The medical provident system does not seem to have much effect upon it, so long as the different clinical teachers are so greedy of the material which out-patients can supply.

THE HUDSON RIVER STATE HOSPITAL FOR THE INSANE.—The Board of Managers of the Hudson River State Hospital met June 21st, and approved plans for the erection of the centre building, which it is expected will be enclosed by autumn, and will take all the money appropriated by the last Legislature.

LONG ISLAND COLLEGE HOSPITAL.—The Commencement of this institution was held at the Brooklyn Atheneum on the evening of June 21st. The degree of Doctor of Medicine was conferred on thirty-four graduates. The Rev. Jesse B. Thomas, D.D., delivered the address, at Dr. H. H. Kane, of the Graduating Class, the valedictorian.

## A CASE OF MENINGITIS

FOLLOWING ACUTE PURULENT INFLAMMATION OF THE MIDDLE EAR—DEATH IN ABOUT TWENTY-EIGHT DAYS FROM THE APPEARANCE OF THE AURAL SYMPTOMS—POST-MORTEM EXAMINATION OF THE BRAIN AND TEMPORAL BONE.

By D. B. ST. JOHN ROOSA, M.D.,

PROFESSOR OF OPHTHALMOLOGY AND OTOLGY IN THE UNIVERSITY OF THE CITY OF NEW YORK.

On the 23d of March, 1877, Mr. A. H. B., *et. 41*, whom I had treated for syphilitic iritis some two years before, sent for me, on account of a severe pain in the right ear. I found the patient, who was a well-developed man, apparently in robust health, sitting up, but giving evidences of great pain. The pain was referred to the depth of the right ear. There was a profuse discharge of blood and pus from the auditory canal; blood predominated, however. The membrana tympani was perforated. The outlines of the ossicles were not seen on account of the swelling of the lining membrane of the tympanic cavity and of the remains of the drum-head. There was some sensitiveness of the tragus and auditory canal, but no especial tenderness of the mastoid process.

The patient stated that on a return from a visit to Memphis and Mobile, or about five days before, he had a bad cold in the head, with severe neuralgic pains in the same region.

Three or four days after the "neuralgia" he consulted Dr. Royal Prescott, through whose courtesy I am able to present the history from that time.

Dr. Prescott says, in a note to me: "Mr. B. came to my office on the evening of March 20th, complaining of pain in the right ear, and deafness on the affected side. He thought that his hearing had been affected for some time on that side. On examination I discovered a quantity of inspissated cerumen, which I removed by gently syringing with warm water. . . . I inserted a few drops of warm glycerine and morphine, put in a pledget of cotton, gave him an anodyne, and directed him to take a saline cathartic. He came in on the following morning and reported that he had passed a tolerable night, that the pain was somewhat abated, but had not wholly disappeared." Dr. Prescott then ordered an infusion of opium, and directed him to remain in the house for a few days.

On March 22d, according to Dr. Prescott's note, the pain had increased, when hot fomentations to the ear and an anodyne were ordered. The patient exposed himself in a severe storm in his last visit to Dr. Prescott's office, and became worse. At this stage I saw the patient. I ordered the application of two leeches to the tragus and the warm douche every hour. My associate, Dr. E. T. Ely, called at nine the same evening, and found him so comfortable that a hypodermic injection of morphia which I had proposed was not administered.

On the 24th, the patient was quite comfortable and free from pain, but he was very restless and did not sleep well. He said that his sleeplessness was not on account of pain in the ear, but on the 25th two more leeches were applied. The discharge from the meatus continued to be very abundant and bloody. The warm douche was continued, and bromide of potassium was given at night. On the 26th there was no pain in the

ear, and no especial tenderness about it, but his head was very uncomfortable and restless. The patient's tongue was heavily furred, his pulse 96, and temperature 101. He was sleepless and without appetite. Cerebral hyperemia was diagnosed, and 10 grains of calomel were ordered at 11 P.M. From the 28th to the morning of the 30th the symptoms were about the same. By the aid of morphia tolerable sleep was secured, but the patient showed great anxiety and discomfort. On that morning, at my request, Dr. Lewis Fisher saw him in consultation, and continued to see the patient with me until his death. Dr. Fisher concurred in the diagnosis, and inasmuch as the patient had suffered from syphilis, he suggested the use of iodide of potassium in addition to the warm douche and morphia. On March 31st the patient had a severe chill at noon, which lasted for an hour, and which was not followed by sweating. The temperature was 100.4 at about 12 noon; at 9½ P.M., 103½. The patient stated that he never had had a malarial attack, although he had spent much of his life in a malarious country. The formation of pus was supposed by Dr. Fisher and myself to be indicated by this chill. There was, however, no tender spot about the ear, and there seemed no chance of getting at the abscess, if one was forming. There continued to be a free discharge from the meatus. We therefore decided to administer quinine, as an antipyretic. We accordingly gave him 20 grains of sulphate of quinine and 30 grains of bromide of potassium, following it up in four hours after with 15 grains of quinine. On April 1st the patient appeared much better. His temperature was 98, his pulse 72, and there was no pain in the ear, and scarcely any in the head. The quinine treatment was kept up. Mr. B. began to sit up, and converse on business matters and became very cheerful, although we had given him a gloomy prognosis immediately after the occurrence of the chill. He did not, however, sleep quite as well as a convalescent should, and on the 12th of April he suddenly complained of severe pain in his right knee joint, and his temperature ran up to 103½. He slept scarcely at all; he also complained of pain in his head, which was not localized. The discharge from the ear diminished very much. The pain in the knee disappeared in about twenty-four hours, and occurred with great severity in the back and left thigh. The mastoid process was cut down upon, on the 9th or 10th, but no disease of the bone or periosteum was detected. On the 15th the temperature was 103½, the pulse 84, and a low muttering delirium occurred at intervals. Prof. John T. Metcalfe saw the patient on this day, and gave his opinion that it was a case of cerebral disease extending from the ear, and although he regarded the prognosis as very unfavorable, suggested the use of mercurial inunctions and iodide of potassium, with a very faint hope that syphilis was causing some of the symptoms. On the 16th the patient was scarcely ever conscious, his temperature continued at 104-104½, and on the morning of the 17th he quietly died.

The autopsy was made by Dr. W. D. Spencer, five and one-half hours after death.

*Head.*—The bones, except the right temporal bone, were normal. The dura mater was normal. The sinuses were filled with dark, soft coagula.

*Brain.*—The vessels on the surface were markedly hyperemic. The vessels at the base appeared normal. In the meshes of the pia mater, most markedly at the base, and equally on both sides, was seen quite an extensive fibrino-purulent exudation, which was thicker along the course of the larger vessels; this exudation extended anteriorly to the surface of the right hemisphere, when it was more sero-purulent. The lateral

ventricles were markedly dilated and filled with blood-stained serum. The brain substance was firm and markedly hyperæmic, otherwise normal as far as examined. The connective-tissue posterior to the external ear and coating the mastoid bone was somewhat oedematous. (This was the site of the incision down to the bone, an incision that was kept open by tents.)

Description of the temporal bone:

*Mastoid.*—There are two discolored spots on a line running outward from the meatus auditorius externus.

*Petrous portion.*—Just in front of the elevation made by the semicircular canals the bone is exceedingly soft. In washing it was broken down, and the whole structure here, or the roof of the tympanic cavity, is found to be in a state of ulceration. An opening through the squamous portion of the bone, or in the temporal fossa would be about on a line with this ulcerated point.

*Lateral sinus.*—The bony wall of this venous canal is disclosed, thinned, and softened throughout about one-half its extent.

*Tympanic cavity.*—The ossicula are intact, but the whole of the membrana tympani is gone.

*Remarks.*—We are all familiar with cases of meningitis resulting from disease of the middle ear of long standing, but cases of this kind following acute aural disease are fortunately more rare. Indeed, we generally expect to subdue an acute inflammation of the ear, if we are able to treat it antiphlogistically within a few days of the outbreak of the disease. Nowhere does rational therapeutics avail more than in acute affections of the ear. In this case there was never a discharge from the ear, according to the patient's statement, until a few hours before I saw him. The affection began as an acute *otitis media catarrhalis*, with impaction of cerumen, which the patient, until corrected by Dr. Prescott, thought was a facial neuralgia—a not uncommon, but dangerous error. It ran a violent course, as is shown by the bloody discharge and great pain.

The purulent process in the middle ear extended to the tissues of the roof of the tympanic cavity, and to the labyrinth and to the membranes of the brain, where the hyperæmia soon became an exudative inflammation of the base, extending very slowly to the upper surface, and consequently leaving the intellect unimpaired for a long time. The disease of the bone went on slowly at the same time. The pyæmic symptoms are explained by the disease of the lateral sinus. The circumstances of the patient, for he lived in a crowded boarding-house, were not favorable to the quiet that should always be secured for a patient with cerebral hyperæmia, and I fear that I did not lay stress enough upon this requisite in the first few days. My suspicions as to cerebral hyperæmia were somewhat lulled, however, during the first forty-eight hours by the fact that the pain in the ear nearly entirely disappeared from the first application of the leeches. The only part of the case that now seems obscure to me, and in this opinion Dr. Fisher agrees, is the reduction of the temperature, and the great improvement in the general condition immediately after the use of the large doses of quinine. We gave quinine, as has been intimated, on the shadow of a hope that we were dealing with a severe case of malarial fever, instead of one of abscess of the brain or inflammation of the meninges. With a diagnosis of either of the latter named, we had simply to sit down with folded arms and await the dissolution of the patient. The reduction of the temperature immediately followed the administration of the quinine, and each day, as it showed a disposition to rise, the same remedy seemed to lower

it, until the septicæmic pains set in, when it utterly failed. Indeed, so well was the patient for about a week, that Dr. Fisher and I were inclined to change our original diagnosis. Such a lull in the symptoms of cerebral disease resulting from an inflammation of the ear, is, however, not without precedent.

There was always an unbroken bone between the ulcerated tympanic cavity and the membranes of the brain, so that the fatal inflammation must have extended through some of the small foramina, which abound in the temporal bone. This is no new pathological observation, since it has long been known, although not always remembered, that we may have meningitis as an extension of aural disease without the occurrence of caries. There was lately a case of acute suppuration of the middle ear, at the Manhattan Eye and Ear Hospital, which resulted in death from meningitis, with rupture of one of the over-distended sinuses, five days after the perforation of the membrana tympani.

### AN INTERESTING CASE OF HYDROPHOBIA AND A QUESTION OF DIAGNOSIS.

By M. STORRS, M.D.,

HARTFORD, CONN.

THE following case of hydrophobia is the only one which has occurred in this city for thirty years. Not only on this account, but from the well-known character and social position of the victim, it has excited great local interest. We will relate the case with accuracy without going into needless detail.

Prof. Alvergnat, æt. 52, was born in Paris. In early manhood he was a soldier in the French army. Of late years he has been a resident of this country, a teacher of the French language, and engaged in literary pursuits; had a good physical organization, with a manly and soldier-like bearing. He was of a nervous temperament, but a man above the average in hope and courage. Deeds of valor are related of his earlier years. His mind was well balanced and philosophical; his library and his literary works bear testimony to his love of study. Added to all he had a firm Christian faith.

On the night of April 30th a strange dog made its way into the hall-way of his house. He offered the dog food, which was refused. Failing to coax him out of the house he attempted to push him on with his boot, when the dog turned furiously upon him and bit him in the leg, chin, and both hands, making a dozen wounds altogether. These wounds were immediately dressed by Dr. Chamberlain, of this city, who washed them with carbolic acid and cauterized them with nitric acid. Nothing peculiar attended their healing. The dog was not supposed at this time to be mad, but was killed the next morning.

Prof. Alvergnat was greatly excited at the time, but after a few days he appeared cheerful, and said to his friends that he thought that he should have no further trouble. He was annoyed by what was said and written to him on hydrophobia and its treatment, but he had settled the plan to be pursued in his own mind, and was less worried by these ill-timed and gratuitous offers of aid. He had, however, a few days before the attack, great nervousness and apprehension, an indefinite feeling of something terrible impending.

On the 29th of May, about 2 A.M., he found great difficulty in swallowing. Drs. Chamberlain, G. J. Hawley, and myself were sent for about 4.30 A.M. Found him in bed, somewhat excited. He said that he had great difficulty in swallowing, and he knew what it meant. He had made himself acquainted with all the

symptoms of hydrophobia, and knew the import of the spasm of the throat. His face was flushed; pulse 120; no headache; no pain except about the chest and from the spasms of the throat when attempting to drink. I spoke encouragingly to him and attempted to soothe him, but he distrusted and regarded all such endeavors as efforts to deceive him. He was perfectly rational, and listened with attention to all that was said to him. His excitement was not in any way loud or boisterous; no rage. He acted as a man would who realized that terrible realities were near at hand, and that but little time remained—perhaps only until the next paroxysm—in which to arrange his affairs, spiritual and temporal. He wished to improve every moment. His minister, lawyer, and other persons whom he desired to see, were at once summoned.

He made his will, attended to all business matters in a business-like manner, conversed with friends, stated to his spiritual guide that he had full faith in Christ, and was ready to meet his God. He had a private interview with his wife in regard to his burial etc., and then seemed ready for the fearful struggle before him. He stipulated that such remedies should be given as would make his sufferings easier to bear.

We first gave him some water in a cup. He took it into his mouth, but in the attempt to swallow it was ejected with great force. It was not vomited, coughed, or spit out, but thrown out without any volition, and in a manner impossible to perfectly imitate. The chin was thrown a little forwards and the head somewhat backwards during the paroxysm. After the fluid was thrown out of the mouth it seemed impossible to breathe for ten or fifteen seconds. It was a catching for breath. A fearful struggle to behold, and such as I have never before witnessed—eyes widely opened, face flushed, with a look of terror and despair. When respiration took place he could exclaim and articulate, though the distress of the paroxysm had not ended.

The paroxysms due to reflex excitability were brought on by the act of swallowing only substances acting upon the throat. Those external causes acting through the special senses—light, sound, and being touched—only started him and added to his fear and anxiety, but did not excite any marked spasm during the first day. We were, however, attentive to everything that could possibly disturb him in this way. I was careful, for instance, to apprise him before touching any part of his body. There were no tetanic or eclamptic spasms.

I have already stated that his mind was clear. He had anxiety and alarm, but he was quieted by soothing words. When quite fearful and apprehensive he wished to cling to some one. He liked to be caressed. He wanted to exchange kisses. Nothing was attempted in the treatment of this case from first to last but to soothe and quiet. We did not seek to eliminate any poison or treat any local complication. We first gave, about 6 A.M., a hypodermic injection of morphine, gr. ss., and atrophine, gr.  $\frac{1}{4}$ . Soon after, we gave a teaspoonful of the following, in sweetened water:

R Bromid. potass.....	ʒ i.
Chloral hydrat.....	ʒ ss.
Fluid ext. scutellae.....	ʒ ij.
Aq. pure.....	ʒ i.
M.	

This was thrown up, as the water before, with the same distressing spasm of the pharynx and larynx. The same was then given as an enema, adding tr. aconit. rad. gtt. ii., and ergot. fld. ext., ʒ ss. This was retained and to be repeated every four hours. He soon became more quiet, but did not sleep. Pulse gradually lessened in frequency, touching 80, the

lowest point. He was thirsty, but every attempt to drink occasioned a severe paroxysm; drinks were, therefore, abandoned. Ice in a napkin was put to his lips. I am inclined to the belief that some of the melted ice ran down the throat without any effort of swallowing. There was no marked increase of the saliva at any time, no biting or gnashing of the teeth.

At 5.30 P.M. he became very much excited. He was soon quieted by giving him larger doses of the above mixture in an enema. At 7.30 P.M. we gave him beef-tea through a glass tube. It excited the spasms as before, but not quite as severely. About a teaspoonful was swallowed. This greatly encouraged the patient, and he said: "Is it possible that I can swallow?" After more of the mixture had been given he slept for three hours, the first sleep since the attack. At 10.50 P.M. I left him, still quiet, for the night, under the care of Dr. Hawley and Prof. Hall. I was recalled in a few minutes. He had suddenly awakened in a paroxysm of difficult breathing, followed by exclamations of fear and surprise, as stated to me on my arrival. We quieted him as before, by his enema.

On my return, about 5 A.M. Wednesday, a very restless night was reported. A spasm every few minutes; great dread of being left alone. He had attempted at intervals to take nourishment. He had swallowed a little with difficulty. Swallowing, however, was not attempted after daylight. The enemata had been increased in frequency and amount during the night, but had not been fully retained. They were now given through a tube, and ʒ ss. of laudanum was added, and they remained up.

There was at this time some delirium and wandering. Previous to this morning no mental disturbance whatever; for the fear and anxiety, so strikingly manifested, seems to have been well grounded, and the delirium now was not more than is often seen when anodynes are freely used. At this time he struck us, the first violence offered. We were persuading him to retain the enema, contrary to his wishes. He soon apologized for this rudeness. Dr. Knight was now called in, and remained with him until death.

The following is from his notes:

Wednesday, May 30th, 8 A.M.—Patient is conscious. Is having spasms. Was given rectal injection of ʒ ij. of the mixture—laudanum ʒ i., ergot ʒ ss.—which was mostly retained, and he soon became quiet. During his sleep, perhaps every twenty or thirty minutes, there would occur two or three inspirations of a spasmodic character, precisely similar in kind to, though less in degree, than the fully developed occurring when awake. About 10 A.M. the temperature was 101°, pulse 100. Pulse remained at this point till afternoon, when it began to rise, and continued to do so until death. When the patient was seized with a spasm the head and shoulders were thrown back, eyes fixed and staring, countenance expressive of great terror. At the same time two or three interrupted spasmodic inspirations occurred, lasting a few seconds; then came an expiration and the spasm passed away. No spasms of the limbs were noticed. As the spasm passed off, the patient was excited, violent, and talkative. All the spasms that I saw seemed to occur spontaneously, or, as occurred several times, were the result of touching the patient, as in wiping his face or putting ice to his lips. At 11.30 A.M. woke with a spasm. Had three or four, and then became quiet without any medicine. At 2.30 P.M. a rectal injection of beef-tea and milk, with ʒ ij. of mixture and ʒ ss. of laudanum, were given without arousing him, and was retained. Sleep continued more profoundly than before. Respiration

now became prolonged and jerking. At 4.50 P.M., while apparently as soundly asleep as at any time, patient suddenly awoke and passed into the most severe spasm that he has yet had. At time of spasm passed contents of bowels in bed. As the inspiratory spasm passed away he threw himself violently about in all directions, so that considerable force was necessary to restrain him. While struggling, by continued and forcible spitting, he freed his mouth of a small quantity of thick saliva. Was given morphine gr.  $\frac{1}{4}$  by hypodermic injection, and soon after gr. viii. of chloral hydrate by the same method, and repeated in fifteen minutes. Had several spasms, but became quiet in about an hour. Slept quietly until 12.30 A.M. Thursday, when he awoke with a spasm of less severity than the previous one. From this time until 2.30 A.M. had ten or twelve spasms. For a short time after a spasm patient was delirious, talking incoherently in French, then would drop to sleep until the next paroxysm. During these two hours ten grains of chloral were given every twenty minutes, hypodermically—sixty grains in all. From 2.30 to 6 A.M. had only four or five spasms, and was given two hypodermic injections of chloral, ten grains each. At 6 A.M. was given a rectal injection of beef-tea and milk, with twenty grains of chloral and  $\frac{1}{2}$  ss. of laudanum. From that time he remained quiet until death, at 9.45 A.M."

We may add that, in the convulsive struggle which occurred at 4.50 P.M. Wednesday, there was no general spasm unless somewhat of a clonic character. The movements seemed both voluntary and involuntary, with an apparent desire to get away from something terrible. He would dash against the bedstead and attempt to throw himself upon the floor. Several men were needed to restrain him. He uttered cries heard far out upon the street, not, as some declared, like the cries of the dog on the evening of the encounter, but it was the voice of the patient modified by his spasms and agony. He spat furiously in all directions.

Drs. G. B. Hawley, Wilcox, Jarvis, and Fuller came in about this time. The chloral, by hypodermic injection, was strongly insisted upon by Dr. Jarvis. Dr. Hawley, S.M., favored and assisted in putting the patient into the strait-waistcoat. He suffered less by this mode of restraint.

Pulse was 120 in the evening before death, and became more frequent and smaller as the case went on. The pupils of the eye remained unchanged until two hours before death, when they began to dilate. Respiration became more regular and easy during this period. He died fifty-six hours from the first difficulty in swallowing, asthenic and comatose, without any asphyxia.

A post-mortem was made five hours after death. Present a large number of the physicians of the city. The following is the result of the autopsy:

*General Appearance.*—The rigor mortis strongly marked. Considerable discoloration beneath the finger-nails, on the neck, and posterior aspect of the body. The wounds slightly reddened. *Head.*—Removing the calvaria, the arachnoid membrane was found somewhat opaque upon the surface of the cerebrum. Its cavity contained considerable serum. Vessels of pia mater were congested. The large vessels were full. Section of cerebrum showed congestion; cerebrum also, but to less extent. The medulla oblongata and upper part of spinal cord were also congested. Nothing of note was found in the chest, except congestion of the lungs. No coagulum was found in the body. The blood was extremely fluid.

*Decomposition.*—The embalming fluid was freely

poured into the abdominal cavity after the post-mortem, and the body was placed on ice. Yet at the end of forty-eight hours it was disagreeable to be near the closed casket in church.

As this case has attained a wide publicity in connection with a supposed theory of death from fright, and also in connection with differences of opinion as regards the particular disease of which the patient died, whether of acute meningitis, of pseudo-hydrophobia, of tetanus, or of acute mania, it may not be inappropriate to analyze the different symptoms which occurred, and attempt to point out the significance of the more prominent ones as bearing upon the diagnosis.

A review of the foregoing history will convince any medical mind that this man did not die of tetanus. There was no trismus; no tetanic spasms. He did not die of acute meningitis, for there was no pain of the head, and no disturbance of vision or of hearing, and no evidence of inflammation was found at the post-mortem examination. He did not die of acute mania. Trousseau says, in substance, maniacs sometimes evince a dread of liquids, and refuse drink. They can swallow, and will generally take liquids to quench their thirst better than food. They are delirious on all subjects, whilst a rabid person retains his reason, except transient hallucinations, to the very end. Our patient did not show any mental aberration like hallucinations, illusions, or delusions, until near the end. Let us look to the element of fear. It is a theory with some that hydrophobia is only fright; that there is no real disease communicated by the bite of a rabid animal. An answer for such skepticism is near at hand, viz., in the undeniable fact, that animals, without fear or imagination, from a similar origin, have hydrophobia in all its aspects, and die. In the case related by us we have a midnight encounter with an infuriated brute. Severe injuries are inflicted. He has the alarm and anxiety that any rational man must have. He commits his case to the care of his medical counsellor, refusing all intermeddling, and calmly, as it appears, awaits the result. He consulted writers upon hydrophobia; but this knowledge was for the purpose of guiding him in his preparations to avoid or to meet any possible danger. To meet a crisis without fear or panic is to understand its nature and to be in readiness for it. So when this disease laid its firm hold upon his throat, he said that he knew what it meant, and calmly conformed to all the requirements of the situation. The fear, the apprehension, and the depression of spirits just preceding the attack are the conditions almost always seen in the genuine disease, whether in the brute creation or in the child too young for reflection or imagination, or in the prime of manhood.

These prodromic symptoms are as much a part of the disease as the fatal ending itself. And as to pseudo-hydrophobia, it is laid down in Reynolds's System of Medicine that this term should not be used; that it has come into use from a faulty diagnosis; that we either have the genuine disease, which kills, or some other disease which furnishes some of the symptoms of hydrophobia, and which disease may or may not kill.

One word more. Those who were acquainted with Prof. Alvergnot knew him to be a thoroughly brave and conscientious man. To say that he died of fright, that he yielded up his life to an imaginary foe, is, in their opinion, an unworthy reflection upon his character and memory.

*Treatment.*—Chloral and morphine were used. Morphine subcutaneously, chloral at first by rectal and

later by hypodermic injections, in quantity and frequency sufficient to control or moderate the violent spasms. It was used as suggested in Ziemssen, as follows: "It is hoped that further experiments will be made with this drug in the form perhaps of clysters combined with subcutaneous injections, with the object of producing euthanasia."

Chloral had more control of the spasms than morphine. Chloral undoubtedly prevented a repetition of the indescribable paroxysms of suffering and agony. It held the patient moderately quiet a large part of the time, a *desideratum* in this dreaded malady. Chloroform was attempted, but was given up on account of the struggles against it.

Recapitulating briefly: We have a man in good health, badly bitten by a dog, since known to have been sick. In four weeks the victim is taken down. He has all the symptoms from first to last which are laid down by our best authorities as belonging to hydrophobia, unless we except the symptom of the increased flow of saliva, which, in many of the cases detailed, has not existed. On the third day he dies. Autopsy reveals no evidence of any other disease.

### CONGESTIVE AND ORGANIC STRICTURE OF THE URETHRA, ACCOMPANIED BY RETENTION OF URINE,

TREATED SUCCESSFULLY WITH WATER PRESSURE BY  
MEANS OF A SYRINGE.

By ALEXANDER HADDEN, M.D.,

NEW YORK.

DURING the last six years quite a number of the above-named classes of cases have come under my care for treatment, and have been uniformly relieved. It is well, perhaps, to mention that they were not complicated by false passages, sinuses, or fistulae, but were simple, chiefly annular, within or immediately anterior to the membranous portion of the urethra, decidedly organic, associated with a spasmodic or congestive condition. The first case which came under my care will represent practically the others. A Mr. M—, a man of ordinarily sober habits, of about 35 years of age, engaged in the milk business in this city, had had gonorrhœa twice, the last time six years before; each time had suffered from gleet several months after; had noticed for a year previous to his calling on me that his urine did not pass freely, and that the stream was growing smaller. When he first called he was suffering from retention of urine. It was early in the morning, about 2 o'clock; had been spending the previous evening with some friends and taken wine freely. I tried all my catheters in turn, both flexible and silver, of nearly all known sizes and forms, but failed. Realizing what the nature of the stricture was, I resolved to try the application of ice-water directly to the stricture through the urethra by means of my uterine syringe, believing that the opposite of Prof. Syme's axiom might hold true, that if water could be passed into the bladder through the stricture, an instrument might be also by care and perseverance, and, besides, the congestion of the part might be so far relieved by the application of cold that the urine might pass out. I accordingly commenced the course of treatment in the following manner: Placed the man on his back on a lounge, knees flexed; filled the syringe with ice-water and passed the nozzle down to the stricture, which was in the membranous portion of the urethra, and compressed the walls of the urethra around the nozzle within about an inch of the end, to prevent the return

of the water, and then made firm and steady pressure on the piston. The first syringe-ful did not pass the stricture after the pressure of fully one minute. I refilled and continued the pressure for about the same time, when the water commenced to pass slowly into the bladder. The contents of the syringe being thrown in, I allowed him to rise, and to his great relief and mine he passed his urine, fully a pint in quantity; stream, however, was very small. This being accomplished, I made an effort to pass a small bougie; succeeded in engaging a number two flexible. This I did not continue in long, as his urethra was sensitive, which any irritation might increase. I then allowed him to go home, gave him pulv. Doveri gr. x., to be taken on going to bed, restricted his drink and diet to flax-seed tea, milk, and farinaceous food. Ordered him to call on me that evening, which he did. He had passed his urine several times during the day with considerable difficulty and pain. I made an effort to pass a sound number three, tapering, but was unable; also number two flexible bougie, which failed. I then resorted to the water application, in the same manner and by the same means as above described, which was kept up for a few minutes, and passed into the bladder with little or no difficulty, which I followed by a number three tapering sound to number four by careful manipulation; this I allowed to remain about ten minutes, at the expiration of which time I syringed his urethra out with tepid water and sent him home, with orders to take a saline cathartic in the morning and to continue the other directions. The following evening he called again; his urethra was less sensitive. Syringed it with cold water, and was able to engage a size larger sound. This treatment was continued until I was able to introduce number six sound and the sensitiveness of the urethra overcome, after which I relied solely on the sound as the means of dilatation. The instrument best adapted for the above purpose is the Davidson syringe, with a long nozzle attachment, like the uterine syringe.

This plan of treatment will, in my opinion, relieve every case of the above-named, and do it without risk of making false passages and other injuries which the means usually employed are likely to do even in skilful hands.

Dr. J. F. Golding proposes to give in a future number of this journal the history of a case, which will clearly set forth the great advantages obtained by the use of this means of dilating strictures of the urethra.

April 21, 1877.

## Progress of Medical Science.

SUFFOCATIVE DISEASES OF THE UPPER AIR-PASSAGES IN BROOKLYN, AND THE RESULTS OBTAINED BY TRACHEOTOMY.—Dr. Pilcher, of Brooklyn, has presented a report to the Medical Society of the County of Kings, in which he gives an elaborate statistical account of the conditions under which croup has existed in Brooklyn during the past seven years, and has made deductions of special interest to practitioners. He uses the term "croup" as including "all forms of acute inflammatory disease of the larynx or trachea, which may produce narrowing of their calibre to such an extent as to occasion serious prolonged dyspnoea," finding on inspection of the official records that any attempt to make sharp distinctions in these affections of the upper air-passages was calculated to mislead.

The chief point of interest in the inquiry centered

about the matter of dangerous dyspnoea, and in relation to it, the allied question of tracheotomy.

According to the tables of the Board of Health, from 1870 to 1876 inclusive, there were 2,769 fatal cases of croup in 80,000 certificates of death. Young persons were, as usual, the chief victims; in fact, 2,300 out of the whole number, and 83 per cent. were under four years of age, and only 30 were ten years or over. The number of deaths in 1870 was 230, but in 1876 had reached the alarming figures of 535. The increase of the population during this period is not given, but the increase of the mortality rate is presumably not to be explained by the increase of the population merely. Among the tenement-house population this is the view taken.

Croup was found, on the general average, to be less fatal in midsummer. In September a decided increase took place, and the highest point was reached in December, an agreement very nearly with what has been noticed in the city of New York.

The following points were noted in regard to the locality of the disease: 1. Each croup district abounded in tenement houses, a fact which is held to be synonymous with crowded, ill-ventilated, and filthy habitations, and an abundance of poorly nourished and delicate children. 2. Each of these foci presented soil conditions of an unfavorable character, that is, they were along the water, or on improperly filled ground, or on the site of old watercourses and the like. In many of them the sewers had become a nuisance, the tide driving in their contents into the cellars. Notwithstanding, however, that the overcrowding of tenement houses in Brooklyn is said to be surpassed in other cities, as in New York, the mortality in the former city is one and a half times greater than New York from these special affections.

Another point showing the close relationship of (so-called) croup and diphtheria, is that the rate of mortality from both rose proportionately from 1870 to 1873 inclusive, while they both reached their highest point in 1875, and then together commenced to decline.

The statistics of tracheotomy are especially interesting, being a more or less perfect record of 121 cases, very few of which have heretofore been published. Of these 97 died. Of the recoveries the oldest one was 52 and the youngest 2½. Twelve were operated on between one and two years and all died. The duration of life after operation in the fatal cases was stated in 66 instances. The time of greatest mortality was during the first twenty-four hours, and on the third day; during each of which periods, 19 died. On the sixth day 4 died, on the eighth day 2, on the fourteenth day 1, and on the eighteenth day 1. The immediate cause of death was given in 62 cases and was as follows: Asthenia in 24 cases, and in 19 within an average of 32 hours; asphyxia from accumulation of exudation below the canula in 16 cases, and within an average of 2½ days; bronchitis and pneumonia in 13 cases, within an average of 4½ days after the operation.

In two instances where chloroform produced dangerous symptoms nitrite of amyl was given. In nineteen instances there was troublesome hemorrhage, and seven appeared to have died from this cause. In one instance the canula was retained twelve months, in another but three days, the shortest period. In nearly every instance tracheotomy was not performed until the patient's condition was desperate, and yet twenty of these operated on recovered. A study of these statistics leads the author to conclude that the first danger for the patient after a tracheotomy is exhaustion produced by one of two causes, or both, viz.: first, the continuous muscular effort which the patient

makes in order to breathe, and second, blood poisoning, which is itself produced by two factors: primarily the toxic influences of the disease itself upon the blood, and secondarily the effect of deficient oxidation. Where there is manifestly systemic poisoning, as in those cases that are ranked as diphtheritic, the toxic agent is still in operation after the tracheotomy, though the other factors just noted that produce exhaustion are eliminated. But then there are other lesions which have to be met. Resulting from the prolonged stenosis of the larynx and trachea, the air within the alveoli has been rarified, and emphysematous dilatations and oedematous infiltration have seriously damaged the lungs. This is to be regarded as the second element of danger, but further the deposit may still extend below the canula and death take place from asphyxia, or, finally, a fatal bronchitis and pneumonia may ensue.

It being clear that the operation of tracheotomy largely tends to avert the elements of danger in suffocative laryngitis, Dr. P. questions the dangers of the operation itself; the first of these he takes to be hemorrhage, the second traumatic fever, and third, plethmoneous inflammation, erysipelas, gangrene and diphtheria of the wound, emphysema, etc. Then comes inhalation of cold air through the tube, and obstruction by pieces of membrane or dried matter. He finds that nearly all of these conditions may be avoided by skill and care in the management of the case. Every individual case must, of course, be studied by itself, while it has to be borne in mind that the expectation of life under five years is materially less than above that period.

Tracheotomy is held to be indicated "in all cases of croup in which laryngeal stenosis becomes so great as to become an element of danger, either immediately, by rapid suffocation, or by a more gradual asphyxia, resulting from a slow accumulation of carbonic acid in the blood; or when, by its long continuance in a less severe form, danger is imminent of the production of diffuse bronchial catarrh or acute oedema of the lungs, or from the exhaustion occasioned by prolonged excessive muscular exertion in sustaining respiration."

The operation should not be deferred until the case is at best a forlorn hope, and as it is no trifling matter should not be considered as a simple procedure that belongs to minor surgery. Skill in operating is known to be of vital importance, and yet distrust of one's self should not serve as an excuse to the medical attendant when a timely operation might save the patient's life.—*Proc. of the Med. Soc. of the County of Kings.*

ON "ORIENTAL SORE" (DELHI BOIL).—The results of the special investigation into the nature and pathology of Delhi boil, undertaken by Drs. Lewis and Cunningham, at the order of the Government of India, have just been published. The report states that the Delhi boil is identical with the sore prevalent in other parts of India, and with the chronic sore known as *houton* in Aleppo, etc. The reporters believe that the cause of the disease is to be found in the character of the water; that the quantity of salts in it, and its extreme hardness, have most to do with the matter, and that organic impurities have no influence. They affirm that the sore is not the direct consequence of general unhealthiness, malarial poisoning, or the like, but that its development is determined by bad water of a particular character; that the salts may not be the actually deleterious ingredients, but the hardness of the water is an index of properties in it which favor the production of cutaneous disease.

In reference to the pathology of the sore, the report is very full. The secretion contains a few blood-corpuscles, a large number of lymphoid cells, and some yellowish white bodies, the size and form of millet-seeds. The last are altered hair-sacs. On examination of a sore extirpated before ulceration, Drs. Lewis and Cunningham found that it is surrounded by a belt of indurated tissue; the skin over it is thinned and eroded, the Malpighian layer deepened, and the papillae enlarged. The even line of the base of the preparation showed no organic connection with the subjacent structure. Lymphoid cells fill every available place in the papillae, invade the corium, and destroy the hair-follicles and glands. The hair-follicles are pushed forward by the new growth, until they are frequently found free on the surface. The sweat-glands are only affected in the severest cases. The cells are distributed about the vessels especially, and are imbedded in a cement substance, having the character of adenoid tissue. No parasitic element is mentioned as having been found.

Drs. Lewis and Cunningham affirm that neither syphilis nor scrofula will account for the disease, but that it is a phase of lupus. Delhi boil "is in no way distinguishable from one or other of the various forms of lupus; its clinical history is similar, as also its morbid anatomy, and the treatment which has proved the most satisfactory is that which is generally recommended for lupus." They add, however, that it may be somewhat modified from its European prototype. Finally they suggest the term *Lupus endemicus* for the Delhi phase of oriental sore.

Dr. Tilbury Fox, in commenting on this report, dissents entirely from the view that the disease is lupus. He shows that the clinical features of Delhi boil and lupus, instead of being similar, are in a great many respects dissimilar. Further, the proved inoculability of the disease; the influence of bad sanitary condition, such as those of place and water in its causation; the epidemic character of the disease; its localization to certain places; its disappearance on the removal of troops from cities to cantonments outside; its liability to attack new-comers; its disappearance for months or years, and the fitful character of the outbreaks,—all go to show that oriental sore is not a phase of lupus. The morbid appearances, as Dr. Fox points out, offer no reliable diagnostic ground, for these are very similar in general features, not only to those of lupus, but also to those of scrofulous ulceration and syphilitic disease, and in minute appearances to those of rodent ulcer and pachydermia. The argument that the same treatment cures Delhi boil and lupus is of no value. Dr. Fox is perfectly convinced that oriental sore is not a parasitic or a lupoid disease, but one *sui generis*. It is a malady having fungicoid or cachectic affinities, and is liable to be confounded with lupus and syphiloderma.—*The Lancet*, April 7, 1877.

**PREVENTION OF EPILEPTIC ATTACKS BY SUBCUTANEOUS INJECTIONS OF APOMORPHIA.**—Dr. Riegel, of Cologne, in the course of his experiments with apomorphia, found that hypodermic injections of the drug prevented to a considerable extent the attacks of epilepsy in a case under his observation. This experience led Dr. Vallender, of Branweiler, to try the remedy in a desperate case of epilepsy, in which the attacks numbered from 10 to 15 in 24 hours. Each attack was preceded by an aura, consisting in a feeling of heat with sharp pain in the epigastric region. The feeling of heat spread from the stomach over the whole of the upper part of the body, while the lower extremities were cold as far up as the knees. After a free interval of a few minutes the attack would follow: cry, loss of consciousness, clonic spasms. One-twelfth of a

grain of apomorphia was injected subcutaneously during the aura, and instead of an attack, a state of syncope with unconsciousness followed, lasting for some minutes. Subsequently only one-twenty-fifth of a grain was used—enough to produce nausea, but not vomiting, and this quantity was injected as often as possible during the aura, sometimes as often as five times a day. It always prevented the attacks, or rendered them much shorter and milder; whereas, when it was not given, the paroxysm was as severe as before. The paroxysms gradually became less frequent and severe, and finally disappeared entirely. The injections were then discontinued, but as the attacks returned, they were resumed after fourteen days, and continued for many weeks. During the eight weeks immediately preceding the writing of this article, there had just been the slightest sign of an attack.

In a second case, the paroxysms lasted a long time, and were repeated several times a day. The aura consisted in a feeling of vertigo, and was separated by a very short, almost inappreciable interval from the attack. In this case it was of course very difficult to make the injection at the right time, *i. e.* during the aura. Nevertheless, the paroxysm was very much shortened after each injection. The treatment was continued several weeks, and the attacks gradually became less frequent. During the last four weeks there had been no return of the attacks.

In a third case, the aura preceded the fit by about a quarter of an hour, and consisted in a pricking feeling beginning in the toes and extending upward, along with a feeling of constriction across the chest, and palpitation of the heart. Whenever an injection was made during the aura, the paroxysm was entirely prevented, but unfortunately the patient did not remain long enough under observation to enable Dr. Vallender to ascertain the influence of the treatment on the frequency of the attacks.

In the first case, the disease had set in suddenly at the age of twenty, and had lasted two years; in the second, the patient had suffered from fits since her childhood, and her mother had been epileptic; in the third, the disease had existed for several years.—*Berliner klinische Wochenschrift*, April 2, 1877.

**THE PERILS OF THE CIGAR.**—Of course there are plenty of men who believe that smoking is positively injurious. We have had it proved over and over again that the man who smokes is sure to die. Even the living smokers who have by mistake grown old cannot dodge this dreadful and indisputable issue. Then, again, before they die, these smokers are said to be addicted to loss of memory (forgetting their promises to reform, no doubt), lack of will power (to stop the habit perhaps), loss of sight, loss of muscular power, taste, smell, feeling, procreative power, and finally idiocy. All this is dreadful and causes us to rejoice that, for a time at least, we have given up the use of tobacco. But there is really a serious aspect to this matter which deserves more than ordinary attention, and that is the liability of syphilitic contamination through the medium of the weed. Recently an English journal cited the case of a young girl, a manufacturer of cigars, who with a chancre upon her lip moistened with saliva the tips of all the cigars she made for a period of three days. This is a well-authenticated case, and it is impossible to say how many more there are like it which are constantly spreading the dreadful poison to unsuspecting pleasure-seekers. The abominably disgusting practice among tobacco-strippers of moistening the leaf with spray from the mouth is doubtless an occasional, if not a common cause of infection.

## THE STATE REPORT ON PAUPERISM.

How to prevent and control pauperism are the problems of the age. Medical men are by virtue of their calling and association particularly interested in everything which may have a direct or indirect tendency in investigating a growing and monstrous evil. The establishment of State Boards of Charities necessarily meets with the hearty approval of every humanitarian who may desire to investigate the subject from a legitimate and authoritative stand-point. The work of these boards has thus far been productive of good in the presentation of the facts connected with the natural history of pauperism, and the suggestion of means for the prevention of the crime. Of course, all investigations are yet in their infancy, but some points are being established which invite thoughtful consideration. The last report of the State Board of Charities\* furnish not a few of these, based upon the careful and discriminative study of the history of pauperism in the different counties of this State.

This report states that among the many factors which help to fill our alms-houses are heredity, habits of idleness, education, disease, old age, insanity, prostitution, the abuse of stimulants, etc. To the last about nine cases out of ten are commonly attributed, but statistics show that only thirty-one per cent. of the inmates of the poor-houses were intemperate. The impossibility of obtaining accurate histories respecting the habits of parents, precludes a proper classification, but sufficient information has been gleaned from keepers and old residents in the rural districts to warrant the conclusion that the mode of life of the parents was often followed by the offspring. The institutions situated at a distance from large cities and towns furnish the most striking cases of heredity, for the

reason that most of the paupers are well known in their respective counties, and cannot migrate without the knowledge of the authorities. About fourteen per cent. of the inmates are the offspring of pauper parents; over three per cent. are from pauper fathers, the rest being from pauper mothers.

Records similar to the following appear in the books of almost every institution: "A family, admitted twelve years ago; wife and child died; father feeble-minded, and two children idiots; preceding generation also paupers." "A woman and daughter, the mother twenty-one, and the daughter seventeen years in the house; parents of woman were paupers, and every member of the family for three generations has at some time been a public charge," etc. These are certainly strong proofs that heredity plays no small part in the causation of pauperism.

There are in the State, it appears, fifty-six county and two town poor-houses and six city alms-houses, containing 12,614 pauper inmates, of whom only 339 are colored. The sexes are about equally divided—6,384 males to 6,230 females. In these various houses are yet 2,179 children under sixteen years of age. Nearly half (45 per cent.) were born in this country, and about one-third (34.31 per cent.) in Ireland. Of the parents, about sixty-two per cent. were of foreign birth. From the whole number, over twenty-one per cent., or 2,656 persons became paupers before they were twenty years old. The average time of dependence for each pauper is 4.88 years. As might have been expected, the ratio of ignorance is large. Of the whole population of the institutions in New York State only twenty-nine per cent. received a common school education, the remainder being comparatively unlettered.

To old age less than seventeen per cent. of the cases are attributed; the largest number, or fifty-nine per cent., of the inmates being between the ages of twenty and sixty, viz., the period of greatest mental activity.

All kinds of reformatory measures have been taken to prevent the spread of this scourge, but, unfortunately, with little success. We read of the system of national workshops in France, in the years, 1790, '91, 1830 and 1848, and the disastrous results thereof; of labor exchange bureaus; of district visiting among the poor; of reformatory institutions; of work, instead of alms; and loans, instead of doles; but none seem to strike at the root of the evil. Beggars go from door to door, and people who should know better insist upon giving them money and clothing, which they generally employ in a very questionable manner. There is one professional beggar in this city who makes from ten to fifteen dollars per day, and who is a public charge, as he goes to the dispensaries, and obtains advice and medicine for himself and family.

The State Board of Charities should enact very strict laws in the workhouses established for the care of vagrants, compelling each inmate to earn his bread literally by the sweat of his brow, and, moreover,

\* Extract from the Tenth Annual Report of the State Board of Charities of the State of New York, relating to the Causes of Pauperism, by Charles S. Hoyt, Secretary of the Board.—State Documents, 1877.

making payments for extra labor performed, thereby encouraging those whom circumstances may have forced into the poor-house. But the more important remedies which are suggested by the report refer to the removal of the children from the alms-houses, and the prevention of the pauperizing influences with which they are surrounded. The control of the hereditary influences has its only hope in the gradual, persistent, and efficient moral, intellectual, and religious education of the depending classes.

#### POLICE RAIDS ON HOUSES OF PROSTITUTION.

EVERY little while we hear of a descent by the police upon what are called disorderly houses. The female inmates are not unfrequently marched through the streets half clad, confined in cells over night, and paraded in court the following morning before some police justice, who fines the malefactors and releases them. We have always failed to see the utility of this measure, either in the light of a prevention or a cure of prostitution. There is a good deal of sentiment concerning this question which is allowed to run into a wrong channel. We cannot imagine anything more pitiable in the brutal exercise of civic authority than the forcible dragging of poor wretches from their homes and inflicting upon them a punishment which is as senseless as it is unjust. The control of prostitution is a question to which the best minds here and abroad have devoted much thought and study, but as yet no plan has been recommended which promises any positive results. We cannot see why the police should be allowed to commit outrages, even upon prostitutes, under the plea of reforming them. The account of a recent raid by the police is but a repetition of former ones, and is full of those details of injustice, indecency, and inhumanity which cause us to blush for advancing civilization.

#### Reviews and Notices of Books.

**HADACHES, THEIR NATURE, CAUSES, AND TREATMENT.** By WILLIAM HENRY DAY, M. D., Member Royal College of Physicians, London, etc. Philadelphia: Lindsay & Blakiston, 1877. 12mo, pp. 308.

This is a carefully written and practical treatise upon one of the most common and yet most intractable maladies with which the human race is afflicted. Our author brings to the discussion of the subject a full appreciation of the latest views concerning the physiological and pathological significance of the various cerebral processes which are associated with the general term headache. The different varieties are as sharply defined as circumstances will admit, their peculiarities intelligently described, while the treatment suggested is in full accord with the most advanced knowledge of functional as well as organic disorders of the cerebrum. The chief value of the work consists in the wealth of resources at the command of the author, and the practical value of his therapeutical suggestions.

#### Reports of Societies.

##### AMERICAN GYNECOLOGICAL SOCIETY.

*Second Annual Meeting.*

WEDNESDAY, MAY 30TH.—FIRST DAY.—MORNING SESSION.

THE American Gynecological Society convened in the city of Boston, May 30, 1877, and was called to order at 10 A.M. by the President, DR. FORDYCE BARKER, of New York.

DR. D. H. STORER, of Boston, delivered the address of welcome.

The following gentlemen were received as members by invitation: Drs. O. W. Holmes, C. Ellis, J. P. Reynolds, and F. Minot, of Boston; G. Kimball, of Lowell; B. E. Cotting, of Roxbury; E. H. Trenholme, of Montreal; J. C. Dalton, of New York; John Scott, of San Francisco; T. M. Reamy, of Cincinnati; and G. J. Garrigues, of Brooklyn.

Dr. Storer offered the facilities of the Medical Library to the members and invited guests.

The first paper for the session was read by DR. JAMES R. CHADWICK, of Boston, and entitled

A NEW THEORY AS TO THE FUNCTION OF THE THIRD SPHINCTER ANI, SO CALLED.

The so-called third sphincter was a thick bundle of muscular fibres, encircling the rectum spirally about three or four inches above the anus. Its function was believed to be simply to further the progress of excrementitious matter and not to retard it.

The second paper was read by DR. JOHN BYRNE, of Brooklyn, on

EXCISION OF THE CERVIX UTERI: ITS INDICATIONS AND METHODS.

Dr. Byrne preferred to use the word excision rather than the word amputation. He first gave a historical sketch of the operation, and then passed to the consideration of the diseases which called for its performance and the means to be employed.

The diseases were considered under the five heads laid down in Dr. Thomas's work on Diseases of Women. The removal of the cervix, or such portions as could be removed with safety, was strongly urged in the treatment of malignant disease. The écraseur was regarded as not being always a reliable safeguard against the occurrence of hemorrhage; there was danger of opening into the peritoneum if an attempt was made to remove the cervix close to the vaginal junction; its use was liable to be followed by septicæmia; and its work was bungling, unscientific, and unsurgical.

The use of the galvano-cautery was discussed at great length, and its advantages fully pointed out. If hemorrhage had followed its use, it was believed to depend upon the operator and not the operation, and occurred because the operator worked too fast and used a wire which was too much heated. The stump should be carefully seared.

With regard to cicatricial contraction following the use of the galvano-cautery, Dr. Byrne believed that it rarely occurred, and never as the direct consequence of excising the cervix by that means; that that troublesome condition was much less likely to follow its use than when the operation was performed by any other method; and that, if cicatricial contractions were almost constant, the method of removal of the

cervix by means of the galvano-cautery was to be preferred to all others in the treatment of malignant disease, because the hot wire produced an effect which extended into the tissues beyond the point of operation. The galvano-cautery was regarded as infinitely safer, and by far the most thorough and radical in its curative tendency of any means that could be employed in the treatment of cancerous disease.

Dr. GOODELL, of Philadelphia, remarked that he was decidedly in favor of using the galvano-cautery in performing amputation of the cervix, but his experience with the hot wire had not been so favorable as that given by Dr. Byrne. The only fatal cases which he had had in removal of the cervix had been after the performance of the operation by means of the hot wire, and yet he preferred its use. The fatal cases he could not use as an argument against the means, because they either could not be attributed directly to the operation, or, being attributed, formed no larger percentage of unfavorable results than might be expected from any other method.

With regard to occlusion of the cervix he had not seen it occur after the use of the *écraseur* or galvano-cautery, but he had seen it occur after the use of a sponge tent and after the use of nitric acid. He agreed with Dr. Byrne that if only partial removal of the cervix could be effected in malignant disease the operation should be performed. He regarded the term cancerous cachexia as a misnomer. He had repeatedly seen it clear up after scraping the diseased surface, and had come to regard it as dependent upon local irritation and not systemic poisoning, and it was not to be regarded as a contraindication to the performance of the operation. One reason why the use of the cold wire was less liable to be attended with hemorrhage was because the mucous membrane could be stitched over the stump so as to heal in that manner instead of by granulation, and the pressure thus produced would prevent secondary hemorrhage.

#### REPORT ON THE CORPUS LUTEUM.

Dr. JOHN C. DALTON, of New York, presented an elaborate report on the Corpus Luteum, in accordance with a resolution adopted at the first annual meeting of the society. The report embraced observations made upon thirty-two sets of specimens sent him by medical gentlemen, in all but two of which the date of the last menstruation or pregnancy was known with reasonable certainty. Some were cases in which menstruation had been suspended from illness or otherwise for a considerable time, but nearly all were of value, in one direction or another, for the purposes of the report. The whole number comprises eight cases of death in non-pregnant women, within the four weeks, of a regular menstrual interval; six cases where menstruation had been absent from five to eleven weeks; six where it had been absent from four months to a year; and two cases in which it had been absent from six years and over; also four cases of abortion from the third to the sixth month; and six cases from one to eight days after delivery at the full term.

The report was divided into two sections: *First*, the Corpus Luteum of Menstruation; and *second*, the Corpus Luteum of Pregnancy. A minute account was then given of the changes which took place in a corpus luteum from the commencement of its formation until its disappearance. The description was amply illustrated by plates made from specimens, and by drawings upon the board. One corpus luteum was described which was removed from the body of a living woman twenty days after the termination of the last menstrual epoch. The deduction was drawn that

there was some direct connection between the rupture of a Graafian follicle, with the formation of a corpus luteum, and the function of menstruation.

There were six cases which presented certain anomalies:

1. Menstruation without ovulation. Four months with regular menstrual epochs, and yet no formation of a corpus luteum.
2. Formation of corpus luteum without central clot.
3. Hemorrhage into or around Graafian follicle without formation of corpus luteum.
4. Blackish discoloration in and about the corpus luteum instead of disappearance of color.
5. Gelatinous and fibrinous exudation from morbid causes into the interior of the Graafian follicle, producing solid tumors.
6. Saccular degeneration of the Graafian follicle. This was the only structure in the ovary which deserved the name of false corpus luteum. The last six cases illustrated the changes which took place during pregnancy, and received but slight notice in the abstract of the report given.

Dr. Dalton acknowledged the receipt of material from Drs. Weir, Howe, L. A. Stimson, Oppenheimer, McLane, Blauvelt, Jayne, Vanderpool, Jr., Beckwith, Whittall, Kelly, Huber, McL. Hamilton, Cushman, Finnell, and Spaulding, of New York; Skene, of Brooklyn; Schenck, of Long Island; Treadwell and Chadwick, of Boston, and Trew, of Ohio.

On motion made by Dr. GOODELL, the thanks of the Society were extended to Dr. Dalton for his admirable report, and the paper was referred to the Committee of Publication.

After the appointment of the Nominating and Auditing Committees, the Society adjourned to meet at 3 P.M.

#### FIRST DAY.—AFTERNOON SESSION.

The Society was called to order at 3 P.M. by Vice-President Dr. BYFORD, of Chicago.

The first order of business was the reading of a paper on

#### DILATATION OF THE CERVIX UTERI FOR THE ARREST OF UTERINE HEMORRHAGE, BY DR. GEORGE H. LYMAN, OF BOSTON.

The Doctor wished to bring forward a single point, namely, that dilatation of the cervix uteri was a valuable means for arresting uterine hemorrhage, and related the history of cases which had led him to that conclusion.

In the first case, although the free dilatation of the cervix did not remove the small fibroid from the anterior lip, yet the hemorrhage was immediately controlled. In the second case there was, after full dilatation, no discoverable cause whatever for the hemorrhage, and yet a menorrhagia and metrorrhagia which had existed for four years was at once controlled, and did not return. The theory was that the dilatation removed the constriction at the internal os not merely by making pressure upon the mucous membrane, but by an effect produced on the deeper tissues, and thereby relieved the congestion above the part constricted. Was it not possible that we had been substituting cause for effect, and was it not possible that hyperplasia of the organ and of its lining membrane was the consequence of constriction of the cervical vessels, as a result of the moderate constriction of the circular fibres surrounding the internal os? The paper was intended to be simply suggestive, and in all the cases the dilatation had been made for purposes of diagnosis, but with the result mentioned.

DR. D. H. STOREY, of Boston, referred to cases in which uterine hemorrhage had been promptly and permanently arrested by dilatation that had been instituted for diagnostic purposes.

DR. WILSON, of Baltimore, remarked that he had repeatedly observed the advantage afforded by the use of tents in arresting uterine hemorrhage, and he regarded Dr. Lyman's explanation as very rational.

DR. A. H. SMITH, of Philadelphia, remarked that he had seen cases in which the patient had suffered for years with uterine hemorrhage, and had been relieved entirely by the single application of a sponge tent, especially when the hemorrhage was attended with much enlargement of the uterus. There was one caution to be given, namely, to be correct in diagnosis, and exclude malignant disease.

DR. JOHN SCOTT, of San Francisco, sustained the remarks of Dr. Smith regarding the exclusion of malignant disease before employing the sponge tent, and suggested as an adjuvant to Dr. Lyman's plan of treatment, after the cavity had been fully dilated, to use injections of hot water (110 to 115° F.), introduced with a Davidson's syringe, for the purpose of washing out all debris which might remain, and at the same time the hot water had an admirable effect in constricting the vessels. The introduction of iodine was also suggested.

DR. GOODSELL, of Philadelphia, suggested that there was another reason, beside those mentioned, why dilatation with a sponge tent arrested the hemorrhage, and that was, when the tent was removed it brought away the cause entangled in its meshes; the little fungoid growths, or perhaps an undiscovered polypus. He related cases in confirmation of this view.

DR. TRENBOLME, of Montreal, remarked, in corroboration of Dr. Lyman's view regarding the *modus operandi* of arresting uterine hemorrhage by dilatation of the internal os, that he had accomplished the same thing by making free incisions through the circular fibres of the cervix from the internal to the external os.

DR. LYMAN remarked, with regard to diagnosis, that of course no one would be so rash as to place a sponge tent in a uterus which was the seat of malignant disease. With regard to the sponge tent bringing away morbid growths which had given rise to the hemorrhage, he could only say that he always employed the *lamina* tent; consequently nothing was caught in its meshes.

#### THE PRINCIPLES OF GYNECOLOGICAL SURGERY APPLIED IN OBSTETRIC OPERATIONS.

DR. A. J. C. SKENE, of Brooklyn, read a paper upon the above subject, in which was set forth the advantages derived from the use of Sims's speculum in performing the operation of craniotomy, returning a prolapsed funis, introducing Barnes's dilators, removal of the ovum in cases of abortion, and in the management of arm and shoulder presentations.

DR. NOEGGERATH, of New York, regarded the suggestions contained in the paper as valuable, especially with reference to the management of prolapsed funis and the introduction of Barnes's dilators. With reference to craniotomy, he had not performed the operation during the last fifteen years, for we had a better method of effecting delivery, namely, by the use of the cephalotribe and the cranioclast. He did not think that the new method of delivery suggested by Dr. Skene was applicable in connection with the use of those instruments, for the reason that the space between the os coccyx and the symphysis pubis would be diminished by the speculum, and because all the

space possible was necessary in order to properly depress the handles of the instrument, especially when the head was to be seized above the pelvic brim. If craniotomy was to be performed instead of cephalotripsy and the use of the cranioclast, then the suggestions made by Dr. Skene would be valuable.

DR. J. P. REYNOLDS, of Boston, gave his assent to the remarks made by Dr. Noeggerath regarding the use of the cranioclast and the cephalotribe, and expressed his surprise at the position of the author of the paper in advancing any modification of the old method of craniotomy. When it was remembered that Braxton Hicks had brought a head safely through a pelvis with an antero-posterior diameter of only one and a half inches, we had said all that could be reasonably asked in the operation.

DR. W. T. LUSK, of New York, called the attention of Dr. Reynolds and Dr. Noeggerath to the fact that when the cephalotribe was used it was preceded by perforation, and that when the cranioclast was employed it was necessary to disarticulate the bones of the skull before the instrument was applied, and therefore in both operations the suggestions made by Dr. Skene could be made available.

DR. JOHN BYRNE, of Brooklyn, remarked that he did not think Dr. Skene's paper had any reference to what method should be adopted in the reduction of the size or in the extraction of the child's head, but it simply made suggestions regarding the best manner of facilitating manipulation in obstetric operations; and in that respect he regarded the suggestions as valuable.

DR. SKENE remarked that he had not thought of disposing of two most valuable instruments, but at the same time thought there were cases in which the narrowing was so marked that, although it might be possible to drag the head of the child through, it was less surgical than to facilitate the removal of the bones by the use of the speculum. He thought the operation of craniotomy would continue to be performed, although we had the new instrument. With regard to narrowing the space by the use of the speculum, that objection was not valid, and Dr. S. believed that it gave instead of taking from.

#### EXCISION OF THE CERVIX UTERI.

The discussion on Dr. Byrne's paper was renewed at this hour, and DR. JOHN SCOTT, of San Francisco, remarked that the first thing to be established was the justifiableness of the operation in any given case. He was of the opinion that pure and simple hypertrophic elongation of the cervix was of rare occurrence, and that, in general, if the real pathological conditions were taken into account, many cases would be eliminated in which the operation had heretofore been performed. Reference was then made to the proof given by Dr. Emmet that laceration of the cervix was one of the dangerous factors in producing hypertrophy and an appearance which in many cases had been regarded as cancer, and had been subjected to excision. With regard to the mode, he had found no difficulty in operating with the scissors, and usually succeeded in getting union by first intention, if the operation was properly performed; the dangers from secondary hemorrhage were very few. His experience did not accord with Dr. Byrne's, for he had seen cases in which the galvano-cautery had been employed, and in which the operation had been followed by the most marked constriction. The thing was in a nut-shell; if the cervix was removed by means of the galvano-cautery the stump must heal by granulation; granulation must be followed by cicatrization, and cicatrization must be followed by contraction. Dr. Scott

believed that amputation of the cervix, at best, was only mutilation, because it left the organ without support, and certainly not in a favorable condition for the use of a pessary. It removed the hypertrophy for the time being, but Dr. Scott maintained that the hypertrophy sooner or later would return.

DR. BYFORD, of Chicago, remarked that he could endorse much that Dr. Scott had said with reference to conservative surgery, but that the particular point upon which he wished to speak was with reference to amputation of the cervix uteri when the seat of malignant disease. He was a strong advocate of the operation, not for the purpose of curing the patient, but for the purpose of giving her relief from many distressing symptoms. He regarded the cancerous cachexia as a species of septicæmia. In cases in which all the diseased tissue could not be removed by amputation, the operation could be supplemented by scraping, and he did not hesitate to scrape into the deeper tissues. With regard to the means, he strongly inclined to the use of the galvano-cautery. He could not help believing that contraction might occasionally follow any means of operating which might be employed.

DR. NOEGGERATH, of New York, closed the discussion by saying that neither Dr. Byrne nor himself had amputated the cervix for fissure or laceration. He had operated thirty-five times with the galvano-cautery, and six times with the knife and scissors. Twenty-five comprised that class of diseases called areolar hyperplasia, simple hypertrophy, etc. Eighteen were cases of malignant disease.

*Sequela.*—Hemorrhage very severe in two cases after the use of the knife and scissors. Secondary hemorrhage after amputation with heated wire in two cases. Of the eighteen cases of malignant disease eight had no relapse up to the present time, and one was operated upon six years ago, and another four years ago. In seven cases pregnancy had followed amputation of the cervix. The danger of constriction after the operation by means of the heated wire he believed to be unduly exaggerated. It had occurred but *once* in the thirty-five cases. He avoided the écarateur because of the danger of opening the cul-de-sac.

The Society then adjourned to meet at 10 A.M., May 31, 1877.

THURSDAY, MAY 31.—SECOND DAY.—MORNING SESSION.

The Society was called to order at 10 A.M. by First Vice-President DR. BYFORD, of Chicago.

REPORT ON THE MUCOUS MEMBRANE OF THE UTERUS.

DR. ENGELMANN, of St. Louis, reported that sufficient material had not been obtained to enable him to make a full report. Several specimens from patients suffering with the so-called membranous dysmenorrhœa had been sent, but thus far they had all proved to be simple casts of the uterus; that is, the superficial layers of the mucous membrane with the glands and blood-vessels belonging. He had not, thus far, found any evidence to controvert his former views concerning the mucous membrane of the uterus during menstruation, namely, that it was not shed, although the uppermost layers were exfoliated.

Additional specimens were solicited.

ON THE NECESSITY OF CAUTION IN THE EMPLOYMENT OF CHLOROFORM DURING LABOR.

DR. W. T. LUSK, of New York, read a paper upon

the above subject, and presented the following propositions:

1. Deep anesthesia, carried to the point of complete abolition of consciousness, retarded, sometimes suspended, uterine action. It was that fact which made it so valuable in many cases, but safety required that the woman should come partially from under its influence before completing labor, in order to avoid hemorrhage.

2. Chloroform, when given in the usual obstetric fashion, might, in exceptional cases, so far weaken uterine action as to create a necessity for resorting to ergot and the forceps.

3. Women in labor did not enjoy any absolute immunity from the deleterious effects of chloroform. A number of cases were related, and the Doctor was not willing to believe they were exceptional.

4. Chloroform should not be given in the *third* stage of labor.

5. The more remote influence of large doses of chloroform during labor upon the puerperal state was a subject which called for farther investigation and inquiry.

DR. WILSON, of Baltimore, remarked that the cases referred to by Dr. Lusk were the first he had heard reported of death from chloroform occurring during parturition. He had used chloroform between two and three thousand times, and with not a single bad result. He always preceded its inhalation by the administration of a dose of some alcoholic stimulant.

DR. A. H. SMITH, of Philadelphia, employed Squibb's ether in ordinary obstetric practice, because it possessed all the advantages of chloroform and was absolutely safe. There were cases in which he wished to produce absolute relaxation and loss of consciousness, and rapidly—for example, for the purpose of instantly carrying the finger to the fundus and removing an ovum, in cases of hemorrhagic abortions, then chloroform was the better agent, and for the short time the patient was under its profound influence, it was ordinarily safe.

DR. GORDON and DR. S. H. TEWKSBERRY, of Portland, Maine, were elected members by invitation.

THE PRESIDENT'S ADDRESS.

The hour of 11 A.M. having arrived, the President, DR. FORDYCE BARKER, of New York, delivered an able and interesting address, in which he paid a high compliment to the Committee of Publication and to the Secretary on his indefatigable zeal and work upon the volume of Transactions, which embraced the labor of the first session of the Society. Fitting reference was made to the death of two Fellows—Dr. Buckingham, of Boston, and Simon, of Heidelberg. Certain practical suggestions were made with reference to the policy of the Society in the future. There was no necessity for haste in filling the list of members. The character of the candidate should be an important consideration. None should be elected except those who had recognized personal and professional eminence. Honorary membership should not be conferred until age exempted from active work, except in instances in which men had made contributions of undoubted value to this department, and which were worthy of special recognition. All should be active working members. It was suggested that a bibliography be added to each volume of the Transactions, which would enhance the merit of the book and increase its sale. Papers should be ready for print at the time they were read; excuses for delay should not be received. Dr. Barker then passed to the consideration of the main subject embodied in his address, namely,

## MEDICAL GYNECOLOGY.

The claims of that department in gynecology were presented in a clear, forcible, and convincing manner, and in no way detrimental to the surgical department, through which so much has been done for the relief of suffering woman. The blessings and benefits which had been conferred by ovariectomy could not be over-estimated, and the same was true of many other surgical operations for the relief of conditions peculiar to the female sex. It was not the province or the wish of the President to detract in the least from the merit to which they were entitled. But there was a field which related to medical gynecology, and which had remained comparatively uncultivated. While there was so much uncertainty regarding many questions in pathology, etiology, and the exact value of symptoms, it was believed to be better not to perform operations, which at best were problematical, but to study the cases and determine, if possible, whether the symptoms could not be removed by correcting functional derangements of the pelvic organs or of certain organs in other parts of the body. Since 1845, immortality had been sought by 142 men in the invention of a pessary, when doubtless more would have been accomplished for the relief of suffering and the preservation of the body had the same energy been displayed in the study of the circulatory, nervous, and digestive apparatuses of the body in their relation to diseases of the pelvic organs. Several cases were reported, and one in which, from psychical influences alone, a cure had been effected as successfully as could have been done by extirpation of the ovaries. "Medical gynecology should bear as important a part in this Society as uterine surgery."

On motion of Dr. GOODELL, of Philadelphia, a vote of thanks was tendered the President for his most admirable address.

## THE INTRA-UTERINE TREATMENT OF FLEXIONS.

Dr. ELY VAN DE WARKER, of Syracuse, submitted a paper on the above subject, which was read by Dr. Chadwick.

Dr. Van de Warker's paper was a clear and candid review of the history of the use of the intra-uterine or stem-pessary, the views of the leading gynecologists all over the world at the present time regarding the propriety of its employment, and a recital of the conditions which warranted its use, and the circumstances which contraindicated its application. It was not claimed as a means of cure, but for the relief of symptoms it was believed to be as safe as any other mechanical support.

After the reading of the paper, Dr. CHADWICK exhibited a pessary which did not involve any new principle, but had a general plan of support simpler than some others.

The discussion on the paper was opened by Dr. E. R. PEASLEE, of New York, who remarked that he was opposed to the use of stem-pessaries in the treatment of retroflexion, when other means would answer, but he was not opposed to their use in antelexion under some particular circumstances. Retroflexion, he believed, could be cured by instruments which did not enter the cavity of the uterus. There was no possibility of changing the antelexed uterus into the upright position, and keeping it exactly in place, except by the use of the stem-pessary. But was it necessary to keep the uterus precisely in one position? If so, the stem-pessary was a necessity. Was it necessary, in order to remove all the symptoms dependent on antelexion, to place the uterus in a certain position and retain it exactly in that position? In most cases he thought

not. Restoration to the first degree of antelexion was all that was required to remove the symptoms in probably forty-nine cases out of fifty. Such result could be accomplished by a more simple apparatus than the stem-pessary, and one perfectly unobjectionable. There were many exceptions to this. As a general proposition it might be stated that, if a woman had no other symptoms except dysmenorrhœa, perhaps sterility, and she was relieved from all congestion at every period, a stem-pessary might be used with safety. In such cases he would use the stem if necessary, but before using it he would resort to another form of instrument. Dr. Peaslee then spoke of the different forms of stem-pessary employed, and described an instrument which he had devised for the treatment of antelexion, and also for retroflexion. In the construction of pessaries he had been guided by three principles: 1. To obtain an instrument which would not make undue pressure under any circumstances; 2. To make use of an instrument which would not be a barrier between man and wife; and 3. To secure an instrument which could be removed and replaced by the patient herself. These three things he had been able to accomplish by means of a circular instrument constructed of tempered whalebone.

Dr. T. G. THOMAS, of New York, remarked that, while he would admit the stem-pessary should have a place in gynecic medicine, he should be very sorry to have Dr. Van de Warker's paper go out from the Society uncontradicted. Dr. Thomas believed that there was an inherent danger attendant upon the use of any instrument which was left in the uterine cavity. Again, the fact was overlooked that a mortality of 1 in 109 of such cases was very much greater than 1 in 4 cases of ovariectomy. Dr. Thomas began the use of the stem in 1855, and used it largely, but soon gave it up, for the reason he learned that every woman who came to his office, and had one introduced into her uterus, went away carrying with her an element of danger which might end in the sacrifice of her life. Dr. Thomas believed that, in spite of all precautions, the use of the stem would, in a certain proportion of cases—not large—be followed by pelvic peritonitis. He had not lost a patient from that cause, but had had a number of cases in which peritonitis had been set up, which came very near terminating fatally. Dr. Thomas did not agree with Dr. Peaslee in his statement that there was no instrument which would keep an antelexed uterus in its place except a stem-pessary. For the proper treatment of congenital antelexion a surgical procedure was required; but a vaginal pessary, with an elbow, rendered much assistance in the after-treatment.

Dr. NOEGGERATH, of New York, moved that the discussion be continued at 3 P.M., after which the Society adjourned to meet at that hour.

## SECOND DAY.—AFTERNOON SESSION.

The Society was called to order at 3 P.M. by Dr. BYFORD, Vice-President.

## DISCUSSION ON INTRA-UTERINE TREATMENT OF FLEXIONS.

Dr. NOEGGERATH opened the discussion, and remarked that he was an advocate of the use of the stem-pessary for the treatment of symptoms coincident with dislocation of the uterus, and not for the cure of the dislocation. He employed it chiefly in antelexion—very exceptionally in retroflexion. He used the stem-pessary constructed of lead, and having wings of hard rubber, and had not met with serious acci-

dent in its employment, except in three cases, during the past fifteen years. He thought that one death in 200 cases was a sufficiently large percentage, and claimed that such a percentage of fatal cases might follow the use of any surgical means that could be employed for the relief of the same symptoms. It must be remembered that there was no application which was made to the uterus, no matter how innocent, but what might be followed at times by bad results. He always introduced the stem at the patient's house, and under the influence of an anæsthetic. He sometimes employed a pessary to diminish the size of the canal, and yet the dysmenorrhœa was relieved, showing that it was not the narrowness of the canal which caused it. The severity of the dysmenorrhœa was not in direct ratio with the acuteness of the angle of flexion.

DR. GOODELL, of Philadelphia, always employed the stem-pessary with trepidation, and yet he did not feel willing to sweep it from the field of therapeutics. Formerly he was of the opinion that the stem was a good instrument to watch. Since that time he had changed his views somewhat regarding the treatment of flexions, and thought there were certain cases which could not be treated well otherwise. He commonly employed Chambers's instrument, always attached a string to it, so that it could be removed at any time, and always made exact measure, so that the pessary was half an inch shorter than the length of the cavity of the womb. He did not wish, by any manner of means, to be understood as saying that the stem was an innocuous instrument.

DR. ALBERT H. SMITH, of Philadelphia, remarked that, according to his experience, anteversion of the uterus was seldom found independent of some pathological condition, something which had affected the integrity of the anterior wall. He had therefore found that it was only very rarely that a pessary was tolerated until that condition was removed. He regarded anteversion as the normal position of the uterus. In retroversion we had a condition which the pessary was specially adapted to relieve. He was not able to endorse the encomiums given to the stem-pessary by the author of the paper. With regard to congenital flexions, he had not seen one but what could be traced to an appreciable cause, which operated first to produce displacement, and subsequently flexion.

DR. W. T. ATLEE, of Philadelphia, remarked that he had had no experience in the introduction of pessaries, but that he had had a large experience in their withdrawal. He had been able to remove the symptoms in most of his patients without the use of pessaries, and when that could be done he was satisfied without their use. With the uterus and pelvic organs in a healthy condition, a change in position of the uterus was of no significance whatever, and there was no use of an instrument to keep it in a certain position.

DR. WILSON, of Baltimore, remarked that he endorsed the remarks of Dr. Atlee, and that he had but little success in the treatment of uterine displacements except in retroversion. He had never seen a pessary with which he could benefit a case of anteversion. Twelve years ago he used the stem-pessary; but he had since discarded it, and never expected to use it again. He was quite confident that there was no such condition as congenital anteversion. He believed that the larger proportion of cases of dysmenorrhœa depended on obstruction of the internal os, and that it was most successfully relieved by making an incision backward from the internal to the external os.

The discussion was continued by Drs. Byford, Garrigues, Skene, Peaslee, Jackson, and Wilson.

The Society adjourned to meet at 10 A.M. Friday, June 1, 1877.

#### FRIDAY, JUNE 1.—THIRD DAY.—MORNING SESSION.

The Society was called to order at 10 A.M. by the President.

The first paper was read by DR. WILLIAM GOODELL, of Philadelphia, on

#### VAGINAL OVARIOTOMY.

His case was the eighth on record, and all occurred in this country. The first case was recorded by Dr. T. G. Thomas, of New York. The following were some of the conclusions reached by the author of the paper: 1. Removal of the fluid from the cyst by means of the aspirator was not without danger. 2. Never tap a polycyst. 3. The case showed that thorough cleansing of the abdominal cavity was required. 4. There was great need of drainage in some cases of ovariotomy.

The paper was discussed by Drs. Kimball, of Lowell; Noeggerath, of New York; Chadwick, of Boston; Lusk and Peaslee, of New York.

#### IS THERE A PROPER FIELD FOR BATEY'S OPERATION?

DR. ROBERT BATEY, of Rome, Ga., discussed the above question, and believed his operation to be justifiable, as follows:

*First.* In those cases in which there was absence of the uterus, and life was injured and health destroyed by reason of the deficiency, removal of the ovaries was at once possible and the only means of affording permanent relief.

*Second.* In cases in which the uterine cavity, or vaginal cavity was obliterated and could not be restored by surgery, if grave symptoms were present, the removal of the ovaries became the last and only resort, and might possibly be invoked in the case.

*Third.* In cases of insanity and epilepsy dependent upon uterine and ovarian disease, the operation was justifiable as a last resort, and when every other means of cure had utterly failed.

*Fourth.* In cases of long and protracted physical and mental suffering dependent upon nervous and vascular conditions and perturbations which have resisted all means of cure, the justifiableness of the operation is to be conscientiously considered by the practitioner in each case.

The paper was discussed by Drs. Trenholme, of Montreal; Peaslee and Noeggerath, of New York; Parvin, of Indianapolis; Goodell, of Philadelphia, and Skene, of Brooklyn.

DR. H. I. BOWDITCH, of Boston, was made member by invitation. The Society then adjourned to meet at 3 P.M.

#### THIRD DAY.—AFTERNOON SESSION.

The Society was called to order at 3 P.M. DR. BYFORD, Vice-President, in the chair.

#### SUBSULPHATE OF IRON AS AN ANTISEPTIC IN THE SURGERY OF THE PELVIS.

DR. WILSON, of Baltimore, gave an abstract of his paper upon the above subject, in which he maintained that the subsulphate of iron was one of the most valuable antiseptics we possessed, in all surgical operations where union by first intention was not expected. For example, in ovariotomy, when there had been ex-

censive adhesions and considerable oozing from the surface after the adhesion had been separated, if the surface was liberally coated with the subsulphate of iron, one part to three of water, after all hemorrhage had been checked, used as an antiseptic and not as a styptic, there would be less of septicæmia than we now see. When the iron was applied to the cavity of the uterus he always combined it with glycerine instead of water. In all severe operations about the vagina, for hemorrhoids, etc., he recommended the dilute solution of Monsel's solution as an antiseptic.

DR. PARVIN, of Indianapolis, reported a case of

#### TETANUS AFTER OVIARTIOTOMY.

He had been able to find only eight other cases on record, and his own was the only one on record in the United States. Since arriving in Boston he had learned of another case which occurred in the practice of Dr. Kimball, of Lowell. There was nothing peculiar either in the history of his case or the condition found at the operation. There were extensive adhesions, and about two inches of the omentum were removed. On the fifth day, the case having progressed favorably up to that time, symptoms of tetanus developed, and the patient died the following day.

DR. KIMBALL, of Lowell, gave a history of his case. There was nothing peculiar in it: the tumor weighed fifty or sixty pounds, and a large amount of the omentum was removed. Tetanus developed on the twelfth day, and the case terminated fatally.

DR. CHADWICK, of Boston, referred to a case of tetanus following an operation for removal of the uterus with a large fibroid.

#### SARCOMA OF THE OVARIES.

DR. W. T. ATLEE, of Philadelphia, reported four cases of sarcoma of the ovaries. The third case was one which had already been reported by Dr. T. G. Thomas, of New York, in the *Am. Journal Med. Sciences* for January, 1876, as a case of adenoma of the ovaries. Attention was directed to the similarity of the four cases, as follows: All occurred in married ladies of the same age—thirty to thirty-two—who had borne children—one to three—and began within twelve or eighteen months after the last parturition; all the tumors were of rapid growth, and had the peculiar feeling of an ordinary cirrhotic liver; all were sulcated, with fan-shaped attachment of the pedicle; all were free from adhesions; all were distinctly pedunculated; and all were free from uterine complication.

Early diagnosis followed by early removal, and the use of arsenic in small doses long continued, offered the most reliable means for effecting a cure.

The paper was discussed by Drs. Jackson, Peaslee, and Engelmann.

DR. ENGELMANN inclined to regard the tumors reported as carcinoma; he judged so from the microscopical reports given.

DR. PEASLEE thought they might as well be called carcinomatous as anything. Three out of four microscopists who had examined the tumor reported by Dr. Thomas had recognized a malignant character, and he, therefore, could not see any propriety of reporting it as a case of adenoma.

DR. GEORGE H. LYMAN, of Boston, read a biographical sketch of the late Dr. Charles E. Buckingham, of Boston.

The following papers were read by title, and referred to the Publication Committee:

The Pathology and Treatment of Puerperal Eclampsia. By PROF. OTTO SPIEGELBERG, of Breslau, Prussia.

The Relation existing between Pregnancy and Phthisis. By DR. WILLIAM L. RICHARDSON, of Boston.

The Value of Electrolysis in the Treatment of Ovarian Tumors, as seen in the Light of Recent Experience. By DR. PAUL F. MUNDÉ, of New York.

Congenital Absence and Accidental Atresia of the Vagina: Mode of Establishing a Canal and Effecting a Removal of Retained Menstrual Blood. By DR. THOMAS ADDIS EMMET, of New York.

The following officers were elected for the ensuing year:

For *President*—Dr. E. R. Peaslee, of New York.

For *Vice-Presidents*—Dr. William Goodell, of Philadelphia, and Dr. Isaac E. Taylor, of New York.

For *Secretary*—Dr. James R. Chadwick, of Boston.

For *Treasurer*—Dr. Paul F. Mundé, of New York.

*Council*—Drs. Atlee, of Philadelphia; Byford, of Chicago; Emmet, of New York; and Skene, of Brooklyn.

For *Honorary Fellows*—Dr. John T. Atlee, of Philadelphia, and Dr. John C. Dalton, of New York; Depaul and Paget, of France, and Scanzoni, of Germany.

For *Resident Fellows*—Dr. Gilman Kimball, of Lowell, Mass.; Dr. A. Dunlap, of Springfield, O.; Dr. A. Reeves Jackson, of Chicago, Ill.; Dr. Edward Wilson, of Philadelphia; Dr. H. J. Garrigues, of Brooklyn; Dr. John Goodman, of Louisville, Ky.; Dr. John P. Reynolds, of Boston; and Thaddeus A. Reamy, of Cincinnati, O.

The retiring President then delivered his address, and introduced the President elect to the Society. Dr. Peaslee responded to the remarks of Dr. Barker, and there being no further business, declared the Society adjourned to meet at Philadelphia on the second Wednesday in September, 1878.

## Correspondence.

### DILATATION OF ONE PUPIL FOLLOWING THE APPLICATION OF A BELLADONNA PLASTER.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—I extract from my note-book the following:

"Mrs. W. applied a belladonna plaster yesterday upon her right side, the skin being somewhat irritated. As a result followed double vision and dilated pupil of the same side. To-day the right pupil is still one-third larger than the left. She removed the plaster yesterday."

This case may be added to the two on page 334, vol. xii., of the N. Y. MEDICAL RECORD, and the one on page 397, vol. xii., of the same journal.

Respectfully,

F. A. BURRALL, M.D.

28 WEST ELEVENTH ST.

A REMEDY FOR BED-BUGS.—A correspondent writes to the *British Medical Journal* as follows: "The best remedy for bugs in hospitals is a bug-trap made by boring a series of holes in a piece of soft wood with a gimlet, and placing this under the mattress of each cot. The piece of wood is to be placed periodically into a basin of boiling water. This is an Indian Hospital plan."

## Medical Items and News.

CONTAGIOUS DISEASES.—Comparative statement of cases of Contagious Disease reported to the Sanitary Bureau, Health Department, for the two weeks ending June 30, 1877.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-Spinal Meningitis.	Measles.	Diphtheria.	Small-pox.
June 23 .....	0	9	93	1	58	38	2
" 30 .....	0	5	88	0	56	32	2

THE VIABILITY OF SPERMATOZOA.—A subscriber writes:—"Please inform me through the medium of THE RECORD, whether or not the spermatozoa of the spermatid fluid cease their active movement, or in other words, become lifeless, when subjected to the influences of an atmosphere of carbolic acid (gr. viii.  $\bar{z}$  i.) under the microscope, and greatly oblige, as I have not the means for determining the above fact."

[We are unable to give any positive information on this point. Will some of our readers answer the question?—Ed.]

NOMENCLATURE OF SKIN DISEASES.—In the adoption of a nomenclature of skin diseases, Dr. L. D. Bulkley has generally followed the plan of the Germans, selecting, as far as possible, words derived from the Greek for the primary name of the disease, while secondary terms are given in Latin. The classification is not a new one, but it presents the entire subject in a concise, clear, and practical manner. Dr. Bulkley relates two cases of morphea, with remarks on the disease and its differential diagnosis. Both did fairly under a mild mercurial ointment, gently and well rubbed into the diseased patches. Tonic remedies have been counselled, but with doubtful results. Iodine has been suggested, as the clinical features of the disease would imply a lymphatic disturbance; but nothing being yet known in reference to the etiology or pathology of morphea, the treatment must be entirely empirical.

MOVEMENT IN THE TREATMENT OF FRACTURE OF THE EXTERNAL CONDYLE OF THE HUMERUS.—Dr. H. A. DuBois, San Rafael, Cal., writes: "In a recent case of fracture of the external condyle of the humerus I applied a felt splint, nearly straight (that being the easiest position), for three days, then with care bent the arm, and changed the splint to one bent at an acute angle, and kept thus alternating the position every two or three days for two weeks, when I resorted to passive motion without a splint. The fracture was well marked, and through the joint. Union had taken place in about twelve days, but the pain, which had been slight before, became after this time greater in making passive movements. Once a day I straightened the arm slowly, but firmly, and kept it in that position for five minutes, and then attached to the wrist a loop of rubber tubing, which passed around the shoulder and was attached to a loop of bandage, which had previously been passed around the other shoulder. In this way a steady pull was kept up for ten or fifteen minutes daily. In six weeks from the fracture all the motions are nearly normal, though the arm is still weak, the only deformity being a slight slipping up of the fragment,

making the breadth at the elbow a little greater than natural. Early and steady movement, I believe, was first advocated by Dr. Bigelow, of Boston; and I would call attention to the fact that there is little pain until callus has been thrown out, and that then the movements must be persisted in if anchylosis is to be avoided, though giving a good deal of pain."

STATE BOARD OF HEALTH OF NEW JERSEY.—In compliance with the provisions of the act entitled, "An Act to Establish a State Board of Health," the Governor has appointed the following named gentlemen as Commissioners: Ezra M. Hunt, M.D., Metuchen; Theodore R. Varick, M.D., Jersey City; James M. Ridge, M.D., Camden; Cyrus Brackett, Prof. Princeton College, Princeton; Laban Dennis, M.D., Newark; Elias J. Marsh, M.D., Paterson; Ezra A. Osborn, Esq., Middletown. The Secretary of State and Attorney General are ex-officio members of the Board.

ON DERMIC MEDICATION.—Dr. G. P. Hachenberg, of Round Mount, Texas, writes:—"In 1852, I reported cases in the *Western Lancet*, on the treatment of certain forms of skin diseases by the dermic medication. The medicine indicated is made in the form of a solution, the woollen underclothes of the patient dipped into it, dried and well aired before wearing them. The perspiration of the skin will redissolve the medicine out of the underclothes, and its continued application to the skin will carry its characteristic effect with it, in many instances, with the same results as when the medicine has been administered hypodermically or through the alimentary channel. Its medicinal effects I have observed in many instances to be in proportion to the degree of perspiration.

This dermic medication is particularly indicated in the weak, either in the chronic or acute form of disease. There are classes of remedies that are particularly effective, administered in this manner, such as astringents, tonics, and sedatives. Indeed the whole range of the soluble salts can be used by this method of medication. For example, I have treated obstinate constipation with a saturated solution of sulphate of magnesia by the shirt; a chronic intermittent fever with a weak acidulated solution of quinine; neuralgia and hysteria with several of the sedative and antispasmodic salts—skin-diseases by alum, borax, chloride, and sulphate of potash, etc.; constitutional depression and paralysis by strychnine. The heroic treatment of using either lead or arsenic in this form I never attempted, believing them not void of bad effects, but I have used the soluble mercuries in some cases with satisfactory results. I have used solution of nauseants by the shirt in affections of the lungs and the mucous tissue in particular, with desired effect. Many of the excessive hemorrhagic and morbid exosmotic operations of the body can, in a great measure, be controlled by the alum-shirt, as colliquate sweats and diarrhoas, and even where the effusions are thrown into the cellular structure not caused by some serious organic disease.

DR. JAMES R. WOOD.—Professor Wood's specimens of lower jaws removed for phosphorus disease, and which were recently sent to the Surgical Congress at Berlin, have attracted a good deal of attention, and have reflected credit upon American surgery.

PENNSYLVANIA STATE SOCIETY.—The Twenty-eighth Annual Session of this society, held at Harrisburg, was, with the exception of the one in Philadelphia, the largest for many years. Many interesting papers were read. Dr. D. Hayes Agnew, of Philadelphia, is the President for the ensuing year.

## Original Communications.

## PNEUMONIC FEVER.

GROUNDS FOR CONSIDERING ACUTE PNEUMONIA AN ESSENTIAL FEVER, AND NOT PURELY A LOCAL INFLAMMATION.

BY AUSTIN FLINT, M.D.

ACUTE pneumonia, in the nosological systems of the present, as of the past time, is placed among the local diseases; and in regard to certain questions, especially in relation to blood-letting, it has been, and is now, generally considered as the type of a purely inflammatory affection. The object of the paper which I shall submit to the Society is to show that this is a false view of its pathology, and that its proper place in nosology is among the essential fevers. That pneumonia is an inflammatory affection, I do not deny. It is the local manifestation, and furnishes the anatomical characteristics of a febrile disease, sustaining to the latter a relation analogous to that which the lesions of the solitary and agminated glands of the small intestines sustain to typhoid fever. I propose as a name for the disease pneumonic fever. This name, if it be established that the disease is not a purely local inflammation, is as appropriate as the name enteric applied to typhoid fever, or the name cerebro-spinal fever to the disease more commonly known as cerebro-spinal meningitis.\*

I am perfectly aware of the duty of brevity in a paper to be read at a meeting of this Society, the sessions of which are short, and the number of papers submitted usually large. I shall present the grounds for considering pneumonia essentially a fever, and not purely a local inflammation, as concisely as possible, avoiding any discussion of the points which will be stated.

In order not to expose myself to the imputation of assuming to advance a doctrine altogether new, I wish to premise that the dependence of pneumonia on a morbid constitutional state is a view which, as I suppose, many, and perhaps most physicians hold. This view, indeed, is applicable to a considerable proportion of the diseases which are reckoned nosologically as local. Of late authors, Juergensen goes further than any with whose writings I am acquainted. This author holds the pulmonary inflammation to be merely the chief symptom of a constitutional disease; that the morbid phenomena are not due to the local affection; that a special cause is indispensable, and that pneumonia belongs to the group of acute infectious diseases.† These assertions are almost, if not quite equivalent to an enunciation of the doctrine expressed by the term pneumonic fever. The arguments offered by Juergensen apply fully to this doctrine; but there are cogent considerations to which he does not refer. In 1866 Dr. Wm. H. Draper, of New York, read to the Academy of Medicine a paper on the treatment of pneumonia, in which he maintained that the pulmonary lesion is a sequence, in point of time, of the pyrexia; that it represents a conservative process by which a

*materies morbi* is eliminated from the circulation, and that there is presumptive evidence of the presence of a specific poison in the blood of persons suffering from this disease. I quote from his paper the following: "These considerations certainly lend support to the theory that pneumonia is something more than a local disease, and is rather an essential fever, having a characteristic lesion like small-pox or scarlet fever."<sup>‡</sup> I have not taken pains to seek in medical literature for similar expressions of opinion. Doubtless they might be found; still, the fact remains, that in our systems of nosology, our treatises on pathology, our text-books of practice, our lectures on medicine, and in medical conversational intercourse, acute pneumonia is recognized as a purely local affection. It is, perhaps, superfluous to premise that by the term acute pneumonia I include only the so-called lobar form of the disease, the form distinguished by German writers as croupous, not embracing broncho-pneumonia nor embolic pneumonia.

The grounds for considering the disease an essential fever relate to its morbid anatomy, its etiology, its clinical history, and its treatment. Following this order, the points which I shall make I will embody, for the sake of brevity, in a series of simple statements or propositions.

1. In relation to the morbid anatomy of pneumonia, the quantity of exudation, amounting to from one to two pounds, if a single lobe be affected, and reaching four pounds if the affection embrace an entire lung; the probable derivation of this matter from the blood in the branches of the pulmonary artery; the removal of the exudation by absorption, leaving the air-vesicles intact; the extension over a lobe by degrees, the progress often being slow; the invasion successively of a second and a third lobe in a certain proportion of cases, and the laws of the disease, as regards the greater liability of the lower lobes, and of the lower lobe of the right lung—these are points which, to say the least, are suggestive of dependence on a constitutional morbid condition, the latter being essentially the disease. It is not easy to reconcile the pathological facts just stated with the doctrine that the products in pneumonia are the results solely of a local inflammatory condition; and if a prior constitutional condition be essential, in view of the symptoms of the disease, the condition is a fever. In some regards the anatomical characteristics of pneumonic fever bear a close analogy to those of typhoid fever.

2. Etiology furnishes support of the doctrine which I advocate in two points of view, namely:

First, the local affection is never produced by local causes; and, second, all the knowledge which we at present have of the causation is in favor of the primary action of the cause or causes being constitutional.

Acute lobar pneumonia is always developed irrespective of any extrinsic agencies acting directly upon the pulmonary organs. Agencies which it might be supposed, *a priori*, would be followed by the disease, fail to produce it. Contusions, however violent, and penetrating wounds of the chest, never give rise to acute lobar pneumonia. It does not follow the diffusion of pus from empyema or an hepatic abscess. Circumscribed gangrene of lung does not lead to it. In bronchitis affecting the small bronchial tubes, the inflammation may extend to certain lobules, producing local effects, however, quite different from the anatomical characters of lobar pneumonia, the latter never occurring, nor does it ever occur, as a sequence of

\* The term *febris pneumonica* was used by the older writers, but without meaning thereby that the disease was essentially a fever. "Lung fever" is a popular term, formerly somewhat in vogue in some parts of this country.

† Ziemssen's Cyclopaedia. American edition, vol. v., p. 114. The term *infectious* is to be understood as defined by German writers, namely, a disease produced by a special cause, or germ, which is capable of being reproduced or multiplied under favorable conditions, either within or without the body.

‡ Bulletin of the New York Academy of Medicine, vol. 11, 1866.

acute pleurisy. Juergensen does not make too strong an assertion when he says that "croupous pneumonia can no more be produced by the excitants of inflammation than can the characteristic intestinal lesions of typhoid fever."

Pneumonia, as is well known, is not infrequently an intercurrent affection in the course of other essential fevers, namely, typhus and typhoid fever, measles, diphtheria, etc. In these instances the determining cause must be constitutional, and yet, as the affection is only an occasional complication, the determining cause involves something which does not necessarily pertain to these fevers. This something, it is reasonable to conclude, is pneumonic fever. Hence, it follows that pneumonic fever may be associated with other febrile diseases. The blending of different fevers may be considered at the present time as a well-established pathological doctrine. An example with which all of us are familiar is the typho-malarial fever.

It is evidence that pneumonia is a constitutional disease (and if so, it must be an essential fever), if it involves a specific causation. A specific cause, with our present knowledge, is not demonstrable; but this confession is to be made respecting other essential fevers—for example, malarial fever. A conclusion can only be reached by the logical force of facts. Certain of these facts belong to the morbid anatomy and to the clinical history. Etiological proof of a specific causation is afforded by the prevalence of the disease at certain seasons of the year, namely, the vernal months in this climate, and its comparatively infrequent occurrence at other seasons. Proof is also afforded by the fact that the disease is far more prevalent in some climates than in others. In our country it is vastly more frequent in the Southern than in the Northern States. Still further proof is afforded by the fact that, at certain times and in certain situations in the South, it has been known to prevail to an extent entitling it to be called an endemic. To these facts it is to be added that at different periods and places the variations of the disease as regards its phenomena and the rate of fatality, constitute a point of distinction from purely inflammatory affections, and affiliate it with the essential fevers.

3. Passing to the clinical history of pneumonic fever, the grounds for using this name instead of acute lobar pneumonia are hardly less substantial than those furnished by the etiology of the disease.

The chill, which is usually the first symptomatic event, is more pronounced than in the history of any purely local inflammatory affection. It is often as marked as in the cold stage of a paroxysm of intermittent fever.

The fever which follows quickly rises, and often in a few hours becomes intense. It is not uncommon for the temperature of the body to be five or six degrees above the normal limit in from four to twelve hours after the attack. Now, this cannot be a symptomatic fever, for within these periods, and often for two or three days, the pneumonic inflammation is so limited as not to furnish the distinctive and easily determined physical signs of the local affection. Contrast, as respects the intensity of the fever at the outset, pneumonic fever with acute pleurisy!

During the course of the disease, the fever, as represented by temperature and other symptoms, has no uniformity of relation with the pulmonary affection. It is impossible to determine by means of the thermometer and by the pulse, together with other symptoms, when the local affection has extended over an entire lobe, or whether more than a single lobe be in-

involved. What is true of typhoid fever, in respect of the influence of the intestinal lesions upon the febrile phenomena, is equally true of pneumonic fever.

As in typhoid, so in pneumonic fever, defervescence is not determined by conditions which relate to the local affection. Defervescence sometimes begins and ends within twelve hours, or even less, and during this time the physical signs may show that no very marked change has taken place in the pulmonary organs. Pneumonic, like typhoid fever, ends from self-limitation—that is, it ends when the disease has finished its career. The duration of this career varies considerably, it is true, in different cases, but it is, nevertheless, self-limited. It is not uncommon for the career of the fever to end when there is much to be done in the way of resolution before the restoration of the normal pulmonary condition is complete.

The analogy to typhoid fever, which in several points of view is apparent, is further shown by the frequent occurrence in pneumonic fever of what are known as typhoid symptoms. It is true these symptoms occur in various diseases; but I am warranted in saying that they occur in pneumonic fever far more frequently than in any other disease, excepting, of course, typhus and typhoid fever. They certainly cannot be attributed to the interruption of the respiratory function, for they are rarely frequent in other affections which occasion greater disturbance of this function—for example, in pleurisy, capillary bronchitis, and asthma. They are undoubtedly due to the fever, irrespective of the pulmonary affection; and, in this point of view, pneumonic resembles typhoid fever.

Pneumonic fever differs from most local inflammatory affections, and resembles most of the essential fevers, in the fact that when the career of the disease has ended, there is no immediate tendency to a relapse. In a large number of cases which I have recorded, in not a single instance was a relapse noted; and I cannot recall an instance in my unrecorded experience. Is there not, in this fact, solid ground for the doctrine that the disease is an essential fever? Another striking fact may be mentioned in this connection, namely, the pulmonary affection never persists in a chronic form. The forms of chronic pneumonia, that is, ordinary and fibroid phthisis, are anatomically distinct from lobar pneumonia; nor does clinical experience substantiate the opinion held by some that phthisis is a sequel of acute pneumonia. It may be asserted of pneumonic, as of typhoid fever, that if death do not take place from either the disease, its complication, or its accidents, recovery follows without any risk of the persistence of the local affection in a chronic form.

4. The therapeutic influence of certain remedies and of antipyretic measures furnishes ground for the doctrine that acute lobar pneumonia is not purely an inflammatory affection.

As long ago as in 1861 I was led, by the results of the analysis of a considerable number of cases in which the sulphate of quinia was given to the extent of only 15 grains daily, to the conclusion that this remedy exerted a marked curative influence upon the disease. I can now bear testimony to the fact that, given in larger doses, namely, from 20 to 40 grains daily, this remedy, in a certain proportion of cases, renders the disease abortive, and that, when this result does not follow, the disease is often favorably modified in a greater degree than by smaller doses. There is reason to think that salicin, in like manner, has a curative influence; the relative value of this remedy not being, as yet, determined by clinical experience. Now, whatever efficacy belongs to these remedies, proceeds, evidently, not from any direct effect upon the pulmo-

nary affection, but from a controlling influence over the pyrexia; hence sustaining the doctrine that the disease is an essential fever. Juergensen, Liebermeister, and other German writers claim, as a conclusion based on clinical experience, that the reduction of the high temperature of the body by cold baths, employed as in cases of typhoid fever, lessens the severity of the disease and the rate of fatality from it. Accepting this conclusion, it is further evidence of the correctness of the doctrine.

Assuming that there are grounds sufficient for adding to the list of essential fevers *febris pneumonica*, or pneumonic fever, we may define the disease as follows:

It is a fever characterized anatomically by an abundant exudative deposit in the air-vesicles of a single lobe, or of two, and sometimes three, lobes of the lungs, with, in general, circumscribed bronchitis and dry pleurisy. It is a fever which rapidly reaches its maximum of intensity, and has a short career, the duration averaging about eleven days. It proves fatal chiefly in consequence of associated diseases, complications, or accidents, and the mode of dying is by asthenia. It is non-communicable, and depends on a cause, or on causes, specific in character, the nature of which is at present unknown, but having relations to season and climate. It sometimes aborts spontaneously; and it is in some instances arrested by remedies. If not arrested, it may be favorably modified, its duration abridged, and the danger to life diminished by treatment addressed, not to the pulmonary affection, but to the fever.

The doctrine which it has been the purpose of this paper to advocate is of interest, regarded simply from a pathological stand-point. It is, moreover, important in a practical aspect, leading the practitioner to regard the rational objects of treatment as relating to the essential disease, that is, the fever, rather than to its local manifestations, and in this way bringing pathology into unison with therapeutics based on clinical experience.

### "AUTOPLASTIC OPERATION FOR TREATMENT OF WEB FINGER, WITH REMARKS."

By P. A. HARRIS, M.D.,

DOVER, N. J.

THE congenital malformation of the hand known as web finger constitutes a deformity of not very rare occurrence. This peculiar formation is not always limited to one hand, neither is it confined to both, as the feet are quite often similarly deformed. Supernumerary fingers and toes are frequently associated with this deformity. In some instances these are merely rudimentary, united by a very slender pellicle of skin and cellular tissue. Again, they are well-formed, having the requisite number of bones, and supplied with muscles. Whether large or small, jointed or pediculated, they are generally characterized by a nail not unlike that of the other fingers or toes.

Every surgeon is familiar with the good results which follow the removal of these supernumerary members, but he is not generally so favorably impressed with the operation for web fingers or toes. True, they may be easily separated by knife or scissors, but they are not so readily kept from reuniting to a considerable extent, thus, in a measure, defeating the object in view. This reunion is produced by granulation and cicatrization commencing at the base of the interdigital space, and slowly advancing toward the

finger ends. The two fingers may be kept separated until the incision is healed, and yet they will often be found reunited for a considerable distance. This distance will become greater in time by the slow but sure contraction of the cicatrix. Aside from or in connection with the precautionary practice of widely separating the fingers, there are two acknowledged means of preventing reunion. To repeatedly cauterize the fresh surface at the base of the interdigital space until the opposing cut surfaces of the fingers are healed; or to pass a narrow band of rubber between the fingers, and attach its respective ends to a bracelet on the wrist. This constant traction is thought to prevent rapid filling of the interdigital space, and retard granulation at that point, while it permits the opposing surfaces of the two members to heal.

Though it is believed that either of these methods has accomplished more than any other, yet they have partially failed, even though skilfully managed.

In the summer of 1875 I was consulted by Dr. Henry Hulshizer, a neighboring physician, in relation to a case of web finger on which he had thought of operating by one or other of the above methods. The fingers were united for the whole of their length, and the interdigital space so nearly filled for a part of the way, that the Doctor expressed doubt regarding successful operation. There occurred to me a plan, simple in itself, yet so promising of success, that it was with difficulty I could persuade myself that the same had not been previously resorted to and described. Friendly physicians and medical literature were consulted for authority. I could find no precedent in the latter, and the former kindly encouraged me in the idea. It appeared to me that if, after the separation of the fingers, the raw surface at the base of the interdigital space could be successfully bridged from the dorsal to the palmar aspects with a strip of healthy skin, that farther granulation would be prevented, the area of cicatrization diminished, and the operation rendered a success. Dr. H. expressed his willingness to the experiment, and in October following the operation was performed.

The patient, at five months, was born with the ring and middle fingers of either hand united almost to the finger ends. To the middle of the second phalanx the attachment was simply cutaneous, being composed of united palmar and dorsal skin. From this point to the base of the first phalanx, the interdigital space was nearly filled with muscular, areolar, and adipose tissue, the palmar portion being level with the surface of the fingers, and the dorsal just slightly depressed.

The patient being etherized, operation was begun by dissecting up from the dorsal interdigital covering a strip of skin three millimetres in width for two-thirds of its length, and from this point widening to ten or eleven millimetres at its dorsal attachment near the metacarpo-phalangeal articulation. The web was then severed, the redundancy of the opposing sides of the fingers snipped off with scissors, and the base of the interdigital space carefully dissected away. The strip of prepared skin was next carried across the base of the interdigital space, cut to the requisite length, and its end secured to the palmar skin by a silk suture. Both hands being thus operated on, they were dressed as follows: A wedge-shaped mass of lint was fitted between the fingers operated on, and held in place by a delicate bandage which encircled the two fingers, the hand, and wrist. This was well sewed to place, frequent stitches being also taken through the wedge to make it doubly secure. A piece of whalebone, made the requisite length, and notched at each end, was laid on the

bandage, and firmly sewed to it over the dorsal wrist, and near the finger-tips. A solution of salicylate of soda was frequently applied, and, on the third day, when the dressings were removed, the parts were found in a healthy state, vitality of both grafts being apparently well preserved. They were dressed as before, and ordered to be left untouched until the return of the attendant. In the interval between the visits, the bandage came off one hand, and was replaced by the mother. On the following day, her efforts were rewarded by the announcement that the graft of that hand had sloughed off.

An examination of the other hand being then made, the graft was found united, and in a healthy condition. Eight days subsequent to the operation the hand bearing the successful graft was entirely well. Recovery of the other, being delayed to a much later day, was accompanied by considerable filling of the interdigital space. This accident occurring to one hand might, in a professional view, be considered almost fortunate, as it afforded opportunity for observing substantially the results of the old and new methods in parallel cases.

To insure success certain conditions are necessary.

- 1st. A healthy subject.
- 2d. Careful preparation of the graft.
- 3d. Avoidance of pressure on graft.
- 4th. Antiseptic treatment of the parts.

This, like any of the other autoplasmic operations, should not be performed on a patient whose vital forces are below par. In dissection of the graft, pinching or compression should be carefully avoided. It is doubtless safer to cut it somewhat longer than required, thus securing a redundancy for grasping by the tenaculum or forceps. This injured portion may then be cut off, and the remainder of the graft nicely fitted, and fastened to the palmar skin. All tissues except the immediate layer of cellular should be removed from its under surface. Tissues at the base of the interdigital space should all be dissected out to a depth somewhat greater than the normal spaces. The dorsal interdigital space being much deeper than its accompanying palmar one, the graft will form an *acute* and not a *right* angle at its point of junction with the palmar skin. Hence the origin of the graft must be at a point almost opposite the metacarpal-phalangeal articulation. If the fingers are united by a simple web, or fibro-cutaneous band, it will be impossible to obtain a graft from the locality chosen in the operation described. In this event, it might be conveniently procured from the dorsum of the hand, removed to the interdigital space by torsion, and the resulting chasm closed by sutures.

It is necessary that attention be given to the care of the graft, for pressure upon it is certain to lower its vitality and produce sloughing. To insure this care, the fingers should not only be kept widely separated, but also well extended for several days. The former may be accomplished by employing a wedge of quilted cotton, in the form of an isosceles triangle with its apex cut off, made as thick as the fingers, and having its base two-thirds as wide as the fingers are long; this wedge to be placed between the fingers operated on, and secured by a snug bandage encircling the two fingers, hand, and wrist. One or two lines of stitching should be then taken across and through the successive layers of bandage; the wedge to be secured in like manner. I can think of no better plan for extending the fingers than the one employed in the operation described. A wooden splint would, however, be equally serviceable. The trouble of sewing the splint on the outside might be saved by including

it in the bandage, but undue and disastrous pressure can be more surely averted by the former method.

Though salicylate of soda was employed in the operation described, other of the more choice antiseptics would doubtless be quite as good. I have delayed the announcement of this operation, hoping for an opportunity for further testing its merits. If, however, this new way did not appear the most rational method of operating, I would not venture to offer it on so limited an experience.

## A NEW MATERIAL FOR DILATATION OF THE CERVIX UTERI.

By G. E. SUSSDORFF, M.D.,

NEW YORK.

It is not my purpose to discuss the treatment of uterine disease by the use of tents, but briefly to describe in this paper a new agent which I have been using for some time as a means for inducing dilatation of the uterine canal, and which I believe superior in many essential particulars to those in general use by the profession at this time, viz.: sponge and sea-tangle.

These have been the only agents relied upon, and yet they certainly fall short of being safe or certain. The sponge is difficult to introduce, is irritating to the tissues, and is liable to induce septic poisoning. Sea-tangle, though better in some respects, is not so good in others. It is difficult to get in sufficient quantity and quality to fully meet the requirements of the gynecologist, and while more cleanly, is expensive and very slow in acting.

Having long since regarded sponge-tents especially with suspicion, and having good reason for believing them to have induced grave local and constitutional disturbance in several of my patients, my distrust has become so great that I now rarely use them. Happily, however, some two years since, while practising in Georgia, I began to experiment with the agent I propose to describe in this paper, and my experience with it has been so uniformly satisfactory that I greatly prefer it to all others. The material of which I speak is the root of the Tupelo tree, a species of *Nyssa* indigenous to the United States. There are four or five different kinds of *Nyssa*, all possessing similar qualities: *N. Uniflora*, *N. Multiflora*, *N. Capitata*, and *N. Aquatica*, are the principal ones. The last named is to be selected for making the best tents. It is a southern species, and grows in swamps and wet places of Georgia and Florida. The roots are the part used. When first dug up from their watery bed they are very heavy, but after being cut in smaller pieces and exposed to dry heat, the water with which they are saturated is evaporated, and leaves them dry and light as cork. It is of fine-grained, but very soft, woody texture; the fibres are not straight, but are interwoven and collected in bundles, which arrangement is peculiar to this genus.

When thoroughly dry, the root is in a suitable condition to be made into tents. For a while I used to make the tents myself, as they were needed, but my means for doing so were imperfect. I have succeeded, however, in having some excellent ones made by Messrs. Tiemann & Co., of this city, who are, I believe, prepared to make them in any quantity. They are easily made, requiring only sufficient compressing force to reduce them to a suitable size for introduction. After cutting the root into a smooth cylinder, a little larger than it is desired to dilate the canal, it is submitted to powerful pressure, by which it may be reduced, if desired, to one-fourth, one-sixth, or even one-tenth its original

size, into a smooth, firm cylinder, which remains so after the force is withdrawn. Before being compressed, they may be most easily medicated with carbonic acid, morphia, belladonna, in fact, anything except acids and astringents, that can be made into aqueous solution, without impairing its expanding power. After the tents are made, they should be kept in a dry place. A few words now with regard to some of the advantages claimed for these tents over others

1. They are easily introduced, being smooth and firm. 2. They will not easily fall out of place, as they are very light, and soon absorb moisture sufficient to retain their place. 3. They are probably of antiseptic nature themselves, or at least will not decompose the fluids with which they are in contact; have none of the offensiveness always accompanying sponge and sea-tangle, and being purely vegetable, are not likely to induce septic poisoning or local irritations. 4. The rapidity with which they will expand when in contact with the tissues and secretions of the uterus, is perhaps one of their chief advantages. From frequent experience with these tents, I have effected dilatation of the cervix in different cases, in various degrees from the size of a goose-quill to that of a silver half-dollar, in actual time ranging from one hour for the smallest to six hours for the largest, and in no instance was this effect accompanied or followed by any alarming or even unpleasant symptoms of nervous shock or local injury. The firm and even pressure obtained from these tents is well calculated to exert a most beneficial alterative influence upon the tissues upon which they operate. In this respect the Nyssa root is far superior to sponge, or even sea-tangle, especially the latter, which is very slow to absorb and expand, often requiring twelve to twenty hours for this purpose. It does not necessarily follow that the new agent is objectionable, because quick dilatation is not always desirable, for the reason that the amount of dilatation can most easily be regulated by selecting such tents as have been compressed, according to a graduated scale, intended to meet every requirement. For instance, for moderate dilatation one of the smaller ones should be used compressed to one-fourth its original size and so numbered, and for rapid dilatation a series of larger ones more thoroughly compressed, say one-tenth their original size. By this procedure a sufficient opening may be effected in from one to six hours, amply sufficient for all the ordinary as well as extraordinary examinations and operations of the gynecologist.

I never have had occasion to use these tents to obtain rapid dilatation of the os in obstetrical cases, but would not hesitate to use them in appropriate cases.

The common form of cylindrical tents enforces equal pressure at the internal as well as external os; but, should different degrees of pressure be desired along the cervical canal, the root can be so cut and shaped before it is compressed that it will meet such requirements, however diversified. When so fashioned it can be so compressed into a smooth, even cylinder which will again resume the shape designed when sufficiently long in situ.

This material may be obtained in considerable quantity, sufficient at least for all surgical purposes, and at comparatively little cost.

There are other uses to which this material can be put by the surgeon. I have in several cases used it for dilating rectal stricture, with good results. I have also frequently made pessaries from this root, and made them impervious by a coating of celluloid to their surface, which gives them also more strength. These pessaries are strong and light as cork.

Believing that we have in this root a most valuable article, calculated to answer many good purposes, I take pleasure in calling the attention of the profession to it, and recommend the tents made from it as I have described them to be superior to all others heretofore used.

## Reports of Hospitals.

### BELLEVUE HOSPITAL.

#### NOTES OF PRACTICE AND PECULIARITIES OF TREATMENT.

##### PHTHISIS—INTERESTING QUESTION IN PHYSICAL DIAGNOSIS—PROGNOSIS MODIFIED BY THE ANSWER.

A MALE patient about forty years of age was taken sick about the 15th of January, 1877, with what he called "a cold." His symptoms were that he began to cough and expectorate a whitish, frothy material, without soreness of the throat, without sneezing, and without feeling any soreness in the chest, and had no recollection of having had chilly sensations or distinct chill. About one week subsequently he had chill, pain in the right side, and was sick in bed for some days. He then improved to such an extent as to be able to be about, but had suffered from occasional night sweats, had become somewhat anemic, occasionally felt a little chilly, and had had cough with expectoration of mucus and muco-purulent material up to the date of physical examination. Aside from having had a chancreoid the man had been healthy. When the chest was made bare it was found, upon inspection, that only a moderate amount of emaciation had taken place, and that upon full inspiration there was no special difference in the expansion of the chest upon either side as compared with the other; perhaps less marked expansion upon the right side. On palpation vocal fremitus was found to be increased over the entire right side as compared with the left, and was especially marked at the upper portion. On percussion, complete dullness was found in the infraclavicular region upon the right side, and less and less complete dullness as approach was made towards the base of the lung; the same posteriorly. There was extra resonance upon the left side anteriorly; full resonance over the entire left side of the chest posteriorly. Upon auscultation there was found to be entire absence of vesicular respiration in the infraclavicular region upon the right side, and there was heard a hollow, blowing sound upon inspiration and expiration, bursting of bubbles under the ear with a metallic sound when the man coughed, a suction noise following cough, as if air was being drawn into a cavity, and a whisper, which was believed to be amphoric rather than bronchial. Similar signs above the spina of the scapula upon the same side posteriorly, and evidence of pleuritic thickening below.

The question arose, did the signs in the infraclavicular region upon the right side indicate the presence of a cavity formed by the breaking down of lung tissue, or one formed by dilatation of a bronchus? Was the respiration bronchial or cavernous? Whether the patient could be promised a possibility of recovery was believed to depend upon the decision of that question.

The history was thought to be against large bronchial dilatation; the sickness had not been of sufficient length. The fact that there was not much emaciation was regarded as evidence against the formation of a cavity, as in ordinary catarrhal phthisis. There was

usually greater evidence of failing vitality, it was said, when a cavity had been formed in catarrhal phthisis than was seen in the patient before us. In the cases in which there was a large amount of consolidation at the apex of the lung, and the patient had shown evidence of the breaking down stage of phthisis, hectic emaciation, etc., it might be said that improvement perhaps would follow change of climate and proper management, but the probabilities of complete recovery were to be regarded as exceedingly small. It was believed that recovery was possible under the circumstances indicated, but after a cavity had been formed it was very rare. While the conclusion was reached in the case before us that the man had a cavity in the upper portion of the right lung, the additional conclusion was reached that it had been produced by changes in the lung substance, which had been active, but had been largely of a croupous character. It was thought that fibrous induration was taking place rapidly, and that if the man could be kept amid the most favorable surroundings, such as a proper climate, etc., there were chances in favor of his recovery.

INTERMITTENT FEVER IN A BOY SIX YEARS OF AGE—  
ATTACK OF WHOOPING-COUGH SUBSEQUENTLY, AND  
FOLLOWED BY EITHER MALARIAL OR HECTIC FEVER.

The interest in the case centred upon the decision of the question whether the symptoms were those of malarial poisoning, or were evidence of the presence of hectic fever. The father stated that two years previously the boy had intermittent fever (giving the symptoms), which continued for one week and was then arrested. From that time forward for sixteen months he continued in good health, when he contracted whooping-cough. Two months after the commencement of the attack of whooping-cough the boy began to complain of being cold at about ten o'clock in the morning, and had fever in the afternoon, continuing until six or seven in the evening, but it was not followed by sweating. The father thought it was the same kind of fever from which the boy suffered nearly two years previously. Nearly six months had passed after the beginning of the fever before the boy was brought for examination.

Physical examination of the chest was made, when there was found slight dullness upon percussion over the lower portion of the right lung posteriorly, and accompanied by a feeble character of the respiratory murmur. It was first thought that the physical signs could be reasonably explained by the presence of the liver in that region, but from the character of the respiratory murmur the conclusion was reached that they were due to the remains of a pneumonia excited during the progress of the whooping-cough, and that the fever was hectic.

ACUTE ARTICULAR RHEUMATISM—CARDIAC COMPLICATION—QUESTIONS IN PHYSICAL DIAGNOSIS.

A male patient had his first attack of acute articular rheumatism six years ago, while at work in a woollen-mill, where he was daily exposed to sudden and frequent changes of temperature from 75° to 95° F. He was suddenly seized with pain in the back, all his joints became swollen, and he was sick seven weeks. No pain in the chest accompanied that attack. Four weeks later, "on account of over-exercise," another attack was induced, which lasted for nine months; no pain in the chest during that time. Recovered, and for fifteen months continued well enough to work. At the end of that time, another attack of rheumatism was developed, which lasted about four months, and when for the first time he had pain in the chest. He

was then twenty-six years of age. The pain was in the precordial region, was stitch-like and severe, and lasted fourteen hours. He was sick about six weeks at that attack, and the pain in the chest continued with more or less severity throughout. There was no cough, no shortness of breath; was able to lie down perfectly well; there was no disturbance of the heart's action, and the pain was not increased by full inspirations. About fifteen months subsequently he began to notice that there was shortness of breath, but not sufficient to give him very much discomfort. From that time until the present attack the patient had not suffered from stitchy pains, cough, or spitting of blood. Present attack was developed eighteen days ago; commenced in the knees, and extended to most of the joints. There was pain in the chest the same as during the preceding attack. It was not increased by long breath, but was aggravated by position, the patient being most comfortable when lying upon his left side.

Physical examination gave a double murmur at the base and evidence of cardiac hypertrophy, the apex beat being two and a half inches to the left of the normal position. There was present also a mitral murmur, which was not conveyed very much beyond the apex. The point of interest in the case, so far as physical diagnosis was concerned, was to determine whether the double murmur at the base was evidence of pericarditis or valvular lesion. It was said that if the case was one of pericarditis there would probably be fluid in the pericardium at that date in the progress of the disease. Evidence was sought by means of percussion, believing that the fluid, if present, would give an increased area of dullness in the precordial region. But the area of dullness was already increased by the hypertrophy, and how, by percussion, was pericarditis with serous effusion to be distinguished from cardiac hypertrophy? The dullness did not extend to the right as well as to the left of the normal area, as it would have done if the pericardium had been distended by fluid, hence the double murmur at the base was regarded as evidence of valvular lesion.

EPILEPSY—PECULIAR AURA—DOUBLE AURA.

The kind of aura in the patient presented was regarded as of very infrequent occurrence, and consisted in the development of a subjective smell just before each epileptic attack; in other words, an olfactory aura. The patient was unable to describe the smell. The second feature in his case worthy of note was the existence of a second aura, which was situated in the epigastrium and about the heart.

FREQUENT SEMINAL EMISSIONS—CONTRACTED MEATUS URINARIUS—OPERATION AND RELIEF.

A young man was presented who had suffered from seminal emissions as frequently as twice during a single night, and had been under various forms of treatment for some time, but without benefit. It was found that he had a very narrow meatus urinarius, and, suspecting that it might be a source of irritation, it was divided so as to admit of the introduction of a 32 bulb with perfect ease. From the day of the performance of the operation the nocturnal emissions had ceased, and all his general symptoms, such as pain in the back and lassitude, etc., had been very greatly ameliorated.

ON THE DANUBE.—The Russian troops on the Danube are suffering extremely from dysenteric and typhoid diseases, and a large part of the men not in hospitals are showing signs of malarial disease.

## Progress of Medical Science.

**GIANT-CELLS IN SYPHILOMATA.**—The question of the existence of giant-cells has always had an interest in connection with the histology of tubercle, of which at one time it was thought these bodies were pathognomonic, though they had really been found in other morbid conditions. In 1876 Baumgarten noticed them in the gummata of syphilis, and Brodowski found them in one case of syphilitic degeneration of the bronchi, and in another of the cardiac muscle. Browicz also records two cases which corroborate these views. A woman of forty, who bore unmistakable evidences of syphilis upon her person, died of pneumonia, and at the post-mortem examination three tubercles, varying in size from a pea to a bean, were found in the anterior wall of the right auricle. In another instance, a woman of forty-five, who died with evidences of constitutional syphilis, there was a tubercle the size of a bean in the larynx, just below the right false vocal cord. In both of these cases the syphilitic deposits contained giant-cells, the former in greater numbers. The tissue was composed, however, principally of round corpuscles, which occurred either singly or in groups, separated by bands of connective material. There were also spindle-cells in the vicinity of the blood-vessels. In a primary ulcer giant cells were sought for in vain.—*Centralblatt f. d. med. Wiss.*, May 17, 1877.

**DOUBLE PHLEGMASIA ALBA DOLENS FOLLOWING TYPHOID FEVER AND ORIGINATING IN NECROSIS OF THE COCCYX AND SACRUM.**—Dr. Dumontpallier reports to the Société de Biologie the case of a young girl who, on the twenty-first day of a typhoid fever, presented a bluish-white painful œdema of the left leg, followed two days later by the same condition in the right. After her death, in addition to the characteristic lesions of typhoid fever, there was found in the primitive iliac veins marked venous coagulation, which extended into the crural. Further examination showed that the hypogastric veins and their branches contained clots of older date than those in the iliac, and that these had their origin in a process of mortification going on in the sacrum and coccyx.—*Gazette Obstetricale*, Feb. 20, 1877.

**IRREDUCIBLE RETROVERSION OF THE UTERUS PRODUCING INTESTINAL OBSTRUCTION AND CURED BY GASTROTOMY.**—M. Koerberé, of Nancy, reported to the Société de Chirurgie a case where a retroverted uterus, which could not be reduced, exercised such pressure upon the intestine as to produce all the symptoms of obstruction of the bowels. For the relief of this, gastrotomy was performed. The uterus was restored by the finger introduced through the wound in the abdominal wall, and the surgeon availed himself of the opportunity to fasten one of the ligaments in the wound, so as to procure adhesion of the uterus to the wall. This resulted in a perfect cure. Of course one ovary was sacrificed, and the operator would not defend the procedure had not the abdomen been already necessarily opened.—*Gazette Obstetricale*, Feb. 20, 1877.

**QUINCKE ON PERNICIOUS ANEMIA.**—Quinke has carefully analyzed ten cases of this disease which he has observed in Berne during the past two years. Men and women were equally affected, and the ages fell between twenty-five and fifty-nine, with one single exception—a girl of eleven. The clinical phenomena were such as

have been described, viz., excessive paleness, slight dropsical swelling in the extremities, weakness, digestive disturbances, anemic murmurs during great cardiac activity, and a small, soft, sometimes wiry pulse. In some cases there was, in addition, actual hypertrophy of the heart, but the valves were intact. The muscular tissue of the heart was anæmic, but not always fatty. Nor were the other organs always fatty. In two of the cases there was jaundice, though after death nothing abnormal was found in the biliary passages. So far as albumen in the urine was concerned, it occurred in rare instances, and then only sparingly. Hemorrhages were seen once during life from the nose and once from the skin, but in the retina they occurred in every case. It was noticed that in the centre of these hemorrhagic spots there was often a brighter, reddish-gray point, which appeared to be due to a deposit of finely granular matter, and was taken to be the remains of lymph corpuscles. Between the choroid and retina, in the myocardium, on the endocardium, on the dura mater, and in the subarachnoid, there were also other hemorrhages. Disturbances of vision were not observed. The temperature of the body was generally normal; sometimes there was a mild, remitting fever of indefinite type. The blood-making organs (spleen, lymphatic glands, and medulla of bones) showed no changes at the autopsies. The development of the disease was always gradual; the entire duration varied between several months and a year. The prognosis he regards as bad, though a fatal issue is not absolutely certain. Of the ten cases two were cured. Special attention in these studies was given to the character of the blood; the entire mass of it was always lessened; the blood itself was always of a bright color, thin, and contained little fibrin. The number of red blood-corpuscles appeared to be diminished, and they were of irregular sizes; in many instances there was an abundance of the smaller red bodies, called *microcytes*. The number of the white corpuscles appeared to be considerably increased in one case, owing to the diminution of the red blood-globules, thus constituting an apparent *leucocytosis*. In other cases there were found among the red globules those opaque or finely granular bodies that are often seen in the blood of cachectic persons. A study of these and similar diseases with which they are associated, such as the more intensive form of simple anæmia and fatty heart have led Quinke to the conclusion that the strict demarcation of them is as yet impossible. As for treatment, proper nutrition is the first thing to be regarded. Transfusion has thus far not been practised with success in these cases, perhaps because it has been employed only in the late stages.—*Berl. klin. Woch.*, 3, 1877.

**ROSENSTEIN ON PERNICIOUS ANEMIA.**—Prof. Rosenstein, of Leyden, reports a case of pernicious anæmia presenting the following points. A farm-laborer of thirty-six was healthy until he contracted typhoid fever, from which he never recovered, and ultimately had swollen feet and diarrhœa. When received into hospital on Nov. 3, 1876, he appeared to be a strongly built man, but presented the following abnormal conditions: Skin and mucous membranes were pale and yellowish; panniculus adiposus moderately developed; temperature ranged from the normal in the morning to 101.7° F. in the afternoon; pulse was between 84 and 108; tongue was thickened, cracked, and pale, but not coated; appetite slight; some diarrhœa; urine contained no albumen; a loud, blowing, systolic murmur, of varying intensity, heard over the apex of the heart, as also over the ostium aortæ; the

abdomen tympanitic; the area of dulness over the liver increased; the blood, on repeated examinations, showed the red corpuscles diminished in number and pale, the colorless ones very little increased; no microcytes could be found; vision was normal, but the ophthalmoscope revealed apoplexies of different sizes on and about the papilla. The patient complained chiefly of headache, especially on sitting up, and of slight cough. He improved under the use of quinine and iron while in the hospital, but died rather suddenly on Dec. 3, with symptoms of effusions into the pleural and peritoneal cavities and œdema of the lungs. At the autopsy the semilunar valves of the aorta were found fenestrated, but all others healthy; the heart dilated, and its tissue distinctly granular under the microscope; liver enlarged, its surface smooth, clear brown color on section, the acini distinct; the spleen large and heavy, its capsule smooth, its color light reddish-brown, and both of these organs contained an excess of iron; kidneys normal, except that they were pale. Prof. Rosenstein directs special attention to these points, viz.: 1. That the disease in this case was not of spontaneous origin, but followed upon the typhoid fever, with which fact the hyperplasia of the liver was probably connected. 2. Extreme pallor was the only abnormal feature of the blood-corpuscles in this case. 3. The intensification of the second sound of the heart with absence of murmurs at the ostium of the pulmonary artery, taken with the other signs, might easily lead to confounding this disease with subacute endocarditis. He attributes especial diagnostic importance to the retinal hemorrhages, which have never been wanting in any case of pernicious anæmia.—*Berlin klin. Wochenschr.*, Feb. 26, 1877.

ON THE APOPLEXY OF THE RETINA IN PERNICIOUS ANÆMIA.—Dr. A. Nykamp, of Leyden, reports the examination of the retina from the foregoing case. There were a number of hemorrhages of a reddish-brown color, but no whitish centre could be seen. The medium sized vessels, after careful isolation, showed occasional lateral or central bulgings of the external coat, which also appeared somewhat thickened without noticeable constriction of the calibre. As a rule, however, the vessels were intact. In some specimens colored blood-corpuscles were observed in the angle where two vessels separated; in other cases a quantity of blood-corpuscles was found around the vessel, and again in others they were partly close to the wall of the vessel, but outside of it, and partly lying in a dilatation of the outermost coat. The red corpuscles were distributed through the retinal tissue in groups of four or five, or larger numbers; in the latter case the centre appeared darker than the periphery, and the whole somewhat granular. There also seemed to be an enveloping membrane. These latter conditions Nykamp considers as referable to the altered conditions of the corpuscles outside of the vessels. He concludes that these hemorrhages are due to diapedesis and not to a rupture of the vessels, the whitish centre described by Manz, and the capillary dilatations being accidental rather than necessary accompaniments.—*Berlin klin. Woch.*, Feb. 26, 1877.

LIGATION OF THE POPLITEAL ARTERY FOR ELEPHANTIASIS OF THE LEG.—Dr. Casati has published his treatment of a case which is calculated to revive a method not much in use now. Paul Bertozzi, a man of fifty-four, was admitted into the hospital of Forlani January 10, 1873. His right lower extremity, from the knee downwards, was enormously enlarged, and exhibited a "mass of crusts and nodosities separated by superficial and dry tortuous furrows," with some points of ulceration. The toes and calcaneum

were the only parts excepted. The patient's general health was poor, though no organic disease was noted except the localized one just stated. On measuring the leg at the calf it was found to have a circumference of fifty-eight centimetres, and above the malleoli fifty. Dr. Casati resolved in this instance to tie on the proximal side, and accordingly the popliteal was taken up January 12, 1873. On February 17th the ligature had come away, and on the 25th the wound was entirely healed. The circumference of the calf was now fifty-four centimetres, a diminution of four; above the malleoli it was forty-eight centimetres, a diminution of two. Towards the end of March the morbid tissue had become remarkably dry and hard, and many of the nodules were easily detached. During April and May following some fragments came away almost daily. On May 26th the circumference of the calf was thirty-six centimetres, a diminution of twenty-two; and above the malleoli thirty-seven, a diminution of thirteen. Combined with an animal and nourishing diet, the arseniate of iron was given. Under these forms of treatment the patient continued to improve. When seen in May of the following year he could walk with a stick, but the leg was slightly swollen and erythematous in color, with some traces of elephantiasis. In June of 1875, more than two years after the operation, the patient was able to walk without a stick, and the œdema and erythema had disappeared. Twenty-four cases of ligation for elephantiasis are cited, with ten recoveries, four improvements, two returns, two non-improvements, and six deaths. As in Vanzetti's case, compression, rest in bed, and bandages were successfully employed, it is suggested that this treatment be given a fair trial before ligation is considered.—*Med. Press and Circ.*, May 16, 1877.

PROPERTIES OF THE HUMAN GASTRIC JUICE.—M. Charles Richet has been studying these matters upon the person of the patient on whom Verneuil successfully performed gastrostomy. He has reached the following conclusions: 1. The acidity of the gastric juice, whether pure or mixed with food, is equivalent to 17 grammes of hydrochloric acid to a thousand grammes of fluid. 2. Acidity increases slightly at the end of digestion, and is independent of the quantity of liquid contained in the stomach. Wine and alcohol increase, but cane-sugar diminishes it. 3. If acid or alkaline matters are introduced, the gastric juice tends to return to its normal acidity. 4. The mean duration of digestion is from three to four and a half hours or more. Food does not pass successively, but in masses. 5. According to four analyses made by a modification of Schmidt's method, it was proved that free hydrochloric acid exists in the gastric juice. 6. It is possible to extract all the lactic acid contained in the stomach, and to prove that there is one part lactic acid to nine parts hydrochloric acid. 7. Following the method of Berthelot, that is, by agitation with anhydrous ether and deprived of alcohol, it can be shown that lactic acid is free in the gastric juice. 8. The question so long in controversy as to the nature of the free acid in the stomach seems almost solved, and it may be said that in every 1,000 grammes of gastric juice there are 1.53 grammes of hydrochloric acid and 0.43 of lactic acid.—*Lyon Medical*, May 13, 1877.

HEALTH RESORTS.—With the present season the advertising cards of the attending physicians of the watering-places are being scattered over the country. Judging from the number of distinguished medical names attached to these cards, references must be cheaply obtained.

# THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

New York, July 14, 1877.

## PROFESSIONAL QUARRELS.

A PROFESSIONAL quarrel, lately inaugurated in this city, has given rise to much comment in medical circles. The almost universal sentiment appears to be one of regret that it should ever have occurred. In this particular instance, the circumstance is the more deplorable, considering the high standing of the parties concerned. Indeed, as acknowledged leaders of professional opinion, the rank and file of the profession are made to look upon these gentlemen as scarcely better than themselves. Under certain conditions it would seem that there is no guaranty against the indulgence on the part of even our best men, in those passions against which, even as children, we were taught to guard. It is not our purpose to mention any names in connection with the remarks we wish to make; for, if to any who may read these lines such names are unknown as associated with the controversy, so much the better for all parties concerned.

The regret at the occurrence of any quarrel always associates with itself an anxiety as to its termination. The error of judgment which commences the difficulty, is seldom corrected by continued discussion. On the contrary, the longer the dispute is carried on, the more the original error is magnified. We think that most quarrels of this sort originate in a mistaken idea of the interest which the public may take in purely personal matters. Generally speaking, we think it is always safe to assume that the principals in these contests have either lacked good advisers or have failed to heed them. In the present instance we explain the matter in one of these two ways, because we believe that any parties to a personal quarrel are incapable of judging for themselves. That the latter remark is applicable to the present misunderstanding is, we believe, an acknowledged and melancholy fact.

At first, of course, it is considered necessary to present what are called merely the facts of a given case.

This may be a matter of history, and may or may not be interesting to the world at large. However that may be, a reply is challenged, and is sure to come. Then there is the usual indulgence in sarcasm, the prejudiced interpretation of motives, sly and countless innuendoes; in fact, every passion is aroused save that which savors of a scriptural regard for the neighbor and brother. And, after all, is it not safe to say, that not only is no one benefited by such procedures, but that all are positively harmed? The profession always suffers from these difficulties. Not only is it made ashamed of itself that such differences should exist, but that their occurrence should be published broadcast to the world. And what is the result of the latter? We merely hear that there is another quarrel among the doctors, and that we are keeping up that reputation of which every one of us is so heartily and deservedly ashamed. How often have we heard outsiders say that we are always quarrelling, and how impotent have we been to deny the charge!

We do not pretend to say which of the parties may thus far have the best side of the argument. This is really of small moment, the question being so personal in all its aspects as to entirely overshadow the principle upon which it is apparently based. The best that we can now wish for it is that it may stop where it is; the best that we might have wished for it, if we could have anticipated what has now happened, would have been that it were never begun.

Personal discussions in journals and in society meetings are bad enough, but there is a power which limits them; but when the warfare is carried on by pamphlets and circulated everywhere, when and how can it be stopped?

## SANITARY INSPECTION OF PUBLIC SCHOOLS.

AT the last meeting of the Medico-Legal Society, the committee having charge of legislative measures to promote the sanitary interests of the public schools, reported progress, regretting their inability at that time to present a complete report of their labors for the past year and a half. They referred briefly to the bills introduced in the late Legislature, namely: one, fixing the minimum age of admission to the public schools at six years, and limiting the attendance to one session a day of children under eight years of age. Another, providing for the appointment of an Assistant Superintendent of Schools for medical supervision. The necessity of the latter office has already been amply demonstrated in these columns.

The importance of the first bill relating to school age would seem to call for further comment. The reasons assigned by the committee, in advocating its passage, are as follows: "Of children under the age of six years, there are now upwards of 17,000 attending the lower grades in our public schools, who could not fail to be greatly benefited by the enactment of such a law, as will be seen for the following reasons:

"The children return to school in the afternoon, af-

ter partaking of a hearty dinner, often fatigued by play, and, during the warm months, overheated, so that the afternoon session is a tax on the vitality of both teachers and scholars, without any corresponding mental benefit.

"Those interested in the health of school-children may satisfy themselves as to the correctness of these statements, by observing the little ones on these sweltering days returning to school after the noon recess, exposed to the burning rays of the mid-day sun, while in the school to be cooped up in crowded rooms during the entire afternoon without any recess, in constrained positions, crammed for the annual examination, tortured by drill exercises for exhibitions (the usual programme at the close of the school year) in order to gratify the vanity of school-officers, who seem determined to run these schools regardless of the physical well-being of the pupils, and the requirements of sanitary laws."

As if these hardships were not enough, the pupils are obliged to sit for hours during these school exercises, listening to buncombe speeches from school-officers and rising politicians; and to complete the farce, after this indispensable part of the programme is over, the managers hurry to other schools, leaving the most important, and what should be the most pleasing part of their duties to the teachers, namely, the distribution of the certificates.

In this connection, there is one point of interest which was not referred to in the report. Not only are the children subjected to the tortures and annoyances already mentioned, of over-crowded and ill-ventilated class-rooms, etc., but frequently, before school is dismissed, the janitor and his assistants begin their work of sweeping and cleaning, raising clouds of dust. As soon as this work is finished, and after the dismissal of school, the doors and windows are closed immediately, thereby preventing proper ventilation. Thus the children are compelled to rebreathe this poisoned atmosphere on their return to school the next day.

In the face of these facts, the School Board has the boldness to assert that the sanitary interests of these schools are properly cared for, and that there is no need of sanitary supervision.

We trust the Medico-Legal Society will not cease its interest in this subject until the Legislature shall, at its next session, as we have every reason to expect it will, enact the necessary laws, placing these schools under proper sanitary control. In the meantime the school board can make amends for past neglect by placing such control in the hands of the Health Department.

**CONTAGIOUS DISEASES IN HOSPITAL.**—There is very little, if any, care taken in the French hospitals to separate contagious from non-contagious diseases, except, perhaps, in cases of itch, concerning which, comparatively speaking, ridiculous precautions are taken.

## Reviews and Notices of Books.

**MYELITIS OF THE ANTERIOR HORNS, OR SPINAL PARALYSIS OF THE ADULT AND CHILD.** By E. C. SEGUIN, M.D., Clinical Professor of Diseases of the Mind and Nervous System in the College of Physicians and Surgeons, New York.

The manifestations of motor and sensory derangement are so varied and complex that it has always been regarded by the general practitioner as most difficult, in diseases of the central nervous system, to associate cause and effect. Thanks, however, to later researches and the skilful grouping of symptoms found in recent literature, the diagnosis of cerebro-spinal disease has been materially simplified. This essay by Dr. Seguin is another valuable contribution to this department of study, and can be commended, not only for its clearness of statement, and for the value of the facts presented, but for its success in rendering more easy the differential diagnosis of changes in the anterior cornua of the cord from other forms of spinal affections. The 120 pages devoted to the subject are divided into nine chapters, the first of which treats of the nomenclature. The second chapter, of over 50 pages, includes merely the simple details of 45 cases. In chapter third, the symptoms of the foregoing cases are studied analytically, and the more important conclusions drawn are:

1st. That in myelitis of the anterior horns of the adult there is no tendency to the occurrence of complete or lasting paralysis of the bladder and rectum, which forms so prominent a symptom of common central myelitis. 2d. As a rule, the anesthesia is but slight and temporary, and in no case is it severe or lasting. 3d. Numbness or formication occurred nearly always at the commencement of the disease. 4th. Muscular atrophy occurred in more than half the cases. 5th. Farado-muscular contractility was, as a rule, much diminished, and in many cases absolutely lost, while galvano-muscular contractility, although generally diminished, was totally lost in but three instances.

Chapters fourth and fifth are devoted respectively to a synthetical study of the symptoms, and to the pathological anatomy. The changes in the anterior horns are found to consist mainly of atrophy of the ganglion cells.

The question of diagnosis in chapter sixth is rendered comparatively simple, from the fact that in most other forms of central disease there is a far more marked reaction to faradism than in the condition under consideration. Etiology, Treatment, and Prognosis are the subjects of the last three chapters. The conclusion is that cold and dampness are the only exciting causes, and in the treatment the main reliance is to be placed on ergot, belladonna, iodide of potass, counter-irritation, and electricity, in various combinations according to special indications. In regard to the prognosis, the author concludes that it is very good as regards life, but unfavorable with respect to the function of paralyzed parts; very few patients recover perfectly from myelitis of the anterior horns.

**CONTRIBUTIONS TO OPERATIVE SURGERY AND SURGICAL PATHOLOGY.** By J. M. CARNOCHAN, M.D. With illustrations. New York, 1877. Harper & Brothers. Parts I. & II. bound together.

This is a quarto, publishing in parts, and having the same scope and aim as Hutchinson's Clinical Illustrations, recently noticed. The parts before us include

a most charming essay on the "Study of Science," in which the true relations of the inductive and deductive methods are duly set forth. This is followed by Dr. Carnoehan's account of the first ligatures of the femoral and of the carotid arteries, for the cure of elephantiasis, together with Wernher's statistics of the operation collated from thirty-two cases. These show that in a few the operation was entirely successful, but that in the majority relapse occurred. In addition, the volume contains remarks on the ligation of the common trunk of the femoral artery in relation to secondary hemorrhage following amputation of the thigh, and in hemorrhage from wounds of the plantar and tibial arteries, with cases. The parts contain two full-page plates, and the work, when finished, will doubtless prove a welcome addition to the library of the practical surgeon.

TRANSACTIONS OF THE MEDICAL SOCIETY OF THE STATE OF NEW YORK FOR THE YEAR 1876. Albany, N. Y.

EITHER through inadvertence or accident, the "Transactions of the Medical Society of the State of New York" have reached us too late to make an extended review. A full report of the proceedings has, however, been published in these columns. The inaugural address by the President, Dr. Thomas F. Rochester, is an able *résumé* of the medical and surgical progress of the times. The remarks concerning ventilation of school-houses shows that most of the children in the public schools are being slowly poisoned by carbonic acid gas, in one school the allotment being only 56 cubic feet of air to each child, instead of 1,000 or 1,500 cubic feet. Attention was also called, very properly, to the question of preliminary education of students, and resolutions regarding thereto, previously passed, reaffirmed. The most interesting papers were those of Dr. S. R. Percy, on the "Comparative Physiological and Therapeutic Action of Free Phosphorus and the Hypophosphites"; Dr. L. A. Sayre on the "Treatment of Rotary-Lateral Curvature of the Spine"; Dr. H. D. Noyes on "Diseases of the Lachrymal Duct"; Dr. Eugene Balch on a case of "Retention of Urine caused by Hypertrophy of the Prostate, treated by the Aspirator"; Dr. L. D. Bulkley on the "Use of Ergot in the Treatment of Purpura"; Dr. T. Dimon on a case of "Disorganization of the Brain without Corresponding Loss of Function"; Dr. A. N. Bell on "The Relations of Unsanitary Conditions to Pauperism, Vice, and Crime"; and Dr. J. W. S. Gouley on "Stone in the Bladder." The volume is very handsomely bound, and altogether a credit to the Society.

PRINCIPLES OF THEORETICAL CHEMISTRY, with Special Reference to the Constitution of Chemical Compounds. By IRA REMSEN, M.D., Ph.D., Professor of Chemistry in the Johns Hopkins University. Philadelphia: Henry C. Lea, 1877.

THE author's intent is to furnish the student with a simple statement of the fundamental principles of theoretical chemistry. In part first, the atomic theory, gaseous elements and compounds, solid elements and compounds, properties of the elements as functions of their atomic weights, and valence or atomicity of elements, are discussed. Part second treats of the constitution or structure of chemical compounds.

The subject of valence is examined as thoroughly as the present knowledge of the subject will admit; but few satisfactory results have been obtained, for the reason that so little is known about it.

The book is worthy of careful perusal, and will be of assistance in determining the basis upon which our conceptions of chemical constitution rest.

## Reports of Societies.

### MAINE MEDICAL ASSOCIATION.

#### TWENTY-FIFTH ANNUAL MEETING.

HELD AT PORTLAND, MAINE, TUESDAY, JUNE 12.

Special Report for THE MEDICAL RECORD.

PRESIDENT'S ADDRESS—ANTISEPTIC SURGERY—SULPHO-CARBOLATE OF SODIUM IN SCARLET FEVER—HYGIENE OF HOMES—SALICYLIC ACID—STRANGULATED HERNIA—STATE BOARD OF HEALTH—OVARIOTOMY—SANITARY CONDITION OF PORTLAND, MAINE.

THE twenty-fifth annual meeting of this Association was held in Portland on Tuesday, Wednesday, and Thursday, June 12th, 13th, and 14th. There were about one hundred and fifty members present, and delegates from the New Hampshire, Massachusetts, Rhode Island, and Connecticut Medical Societies.

Tuesday morning was spent principally in routine business. A paper on Rheumatism, by Dr. Webster, and one on Otolgy, by Dr. Holt, were received.

At the opening of the afternoon session, the President, Dr. E. F. Sanger, of Bangor, delivered the annual address. After recounting briefly some of the important discoveries in medicine and surgery which have been made during the century, the credit of which is due to American physicians, he proceeded to take up some matters of practical interest to the Association. He advised that the Association make a new effort to obtain from the next Legislature a law providing for a State Board of Health. Also that the Association petition the Legislature to enact a law compelling parties suing for malpractice to give bonds to pay all taxable costs in case of defeat. Suggestions were also made upon medical education, the Pharmacopœia, and the metric system. Subsequently special committees were appointed upon these several subjects.

DR. FILES, of Portland, read a paper on "Antiseptic Surgery." In the discussion which followed, it was the opinion of most that, in the great majority of cases, as good results could be obtained by scrupulous cleanliness, complete arrest of hemorrhage, and perfect coaptation of parts, as by Lister's method.

DR. HUTCHINSON read a report upon the use of "Sulpho-carbolate of Sodium in Scarlatina," giving a series of cases in which the remedy seemed to exert a powerful influence for good; also some cases in which it seemed to possess prophylactic power.

In the evening DR. HASKELL, of Stockton, read a very interesting and practical paper on "The Hygiene of our Homes," which was the conclusion of a paper presented at the last meeting. In this paper he took up the subjects of food and water, dwelling particularly upon milk, and the importance of obtaining it from cows that were not only healthy, but were well cared for.

DR. GERRISH, of Portland, presented a report upon "Salicylic Acid," which was a synopsis of reports of the actual experience of forty (40) members of the Association. The conclusions drawn were that it was of great value in acute rheumatism; of some value in chronic and muscular rheumatism, but uncertain; of no special value in neuralgia, diphtheria, etc.; and very efficient for local use as a disinfectant and deodorizer.

The remainder of the evening was taken up by reports of committees.

WEDNESDAY, JUNE 13.

In the morning DR. TEWKSBURY read a report of a case of fibroid tumor of the uterus, and made some general remarks upon the subject.

DR. SMALL, of Portland, then read a paper on "Anesthetics in Obstetrics," and was followed by DR. DONNOVAN, of Lewiston, by one on Necrosis.

DR. BRAY, of Portland, read the report of an interesting case of "Strangulated Hernia; Slough of Intestine; Recovery with Artificial Anus," which occurred in the practice of Dr. Tewksbury. The patient was first seen March 6th, the fourth day after strangulation took place. On opening the sac, the intestine was found to be gangrenous, and eight inches of the ilium was removed, together with an undescended testicle, which was also gangrenous. The open extremities of the intestine were stitched to the wound. The patient was in a state of profound collapse, no pulse at the wrist, and constantly vomiting fecal matter. For an hour whiskey was administered subcutaneously, in drachm doses, every few minutes. Reaction then came on, and from that time recovery took place without interruption. He went out of the house for the first time on May 30th. He was presented to the Association, and had the appearance of a man well nourished. The fecal discharge is controlled by a hard rubber plug, which is held in place by an elastic bandage, and a tube is run through the plug, which is provided with a stopcock to allow the escape of gas. The plug is removed once or twice daily, and a free evacuation of the bowels takes place.

At the opening of the afternoon session, the following officers were elected: *President*, T. H. Jewett, South Berwick; *Five Presidents*, P. S. Haskell, Stockton, W. Osgood, North Yarmouth; *Treasurer*, T. A. Foster, Portland; *Recording Secretary*, C. O. Hunt, Portland; *Corresponding Secretary*, S. H. Weeks, Portland; *Board of Censors*, F. H. Gerrish, Portland, H. H. Hunt, Gorham, A. J. Billings, Freedom, A. J. Fuller, Bath, J. A. Donovan, Lewiston.

DR. FRENCH, of Portland, Chairman of the Committee on State Board of Health, presented his report, giving the causes of failure with the last Legislature, of which the following is a sample: "One gentleman on the Judiciary Committee, representing a manufacturing interest, was apprehensive that the factories might incur expense in being compelled to make some provision for the escape of operatives in case of fire, or that a similar outlay might be required to improve the ventilation. The same gentleman innocently inquired whether the disclosure by a State Board of Health that tenement-houses in a certain locality were unhealthy, or that a certain tract of land was unsuitable for building purposes, might not be prejudicial to the interests of landlords and real estate owners." The committee was continued, with the addition of three new members, and were instructed to make another effort before the next Legislature.

DR. GREENE, of Portland, presented an abstract of a paper on the treatment of fractures of the elbow-joint.

DR. BRACKETT, of Augusta, presented an abstract of a paper on the History of Ovariectomy in Maine. The first operation performed in this State was by Dr. McRuer, of Bangor, in 1853. The whole number of operations of which he had obtained the records was ninety-six, of which fifty nine were successful.

The evening session was occupied in listening to

the annual oration by DR. GEORGE F. FRENCH, of Portland, his subject being Materialism. It was an able argument against the materialistic tendencies of the day.

THURSDAY, JUNE 14.

After the transaction of business, DR. BROWN, of Paris, read an interesting history of three cases of fracture of the skull, two of which resulted in recovery, with partial paralysis, and the other in death, five months after the injury, from abscess of the brain.

DR. GERRISH, of Portland, read a report upon the Sanitary Condition of Portland, considering the following points: vital statistics, the prevalence of infectious diseases, the condition of the sewers, and the character of the water. He concluded with the following practical suggestions: "In the first place, we should have some adequate system of registration of vital statistics; this would necessitate an entire overthrow of our present method. Births should be recorded as well as deaths, and medical attendants should be required, under suitable penalty, to make report to a registrar of all the necessary data with regard to decedents who have been under their care. Next, we should have many improvements in our sewer system, and have them at once. Our method of disposing of excreta and offal other than by the sewers needs thorough reformation, as at present it is a source of a vast amount of sickness and death. Our water supply should be under the supervision of the city authorities. Measures should be taken to stamp out scarlet fever, a disease which is far more destructive to life in our community than is small-pox. Above all, our citizens need to be educated with reference to these vital matters, and shown the crying need of taking active steps in protecting their lives and the lives of their children."

DR. SPALDING, of Portland, read a paper on The Ophthalmoscope in Medicine.

The report on Necrology was made by DR. HORN, of Lewiston, from which it appeared that the Association had lost during the year eight members, and what was noticeable five of the eight were among the original members of the Association.

The Association then adjourned to the second Tuesday of June, 1878.

NEW HAMPSHIRE MEDICAL SOCIETY.

*Eighty seventh Annual Meeting.*

HELD AT CONCORD, N. H., JUNE 19-20, 1877.

DR. A. B. CROSBY, PRESIDENT, IN THE CHAIR.

(Special report for THE MEDICAL RECORD.)

TUESDAY, JUNE 19TH.

THE eighty-seventh annual meeting of the New Hampshire Medical Society was held in Rumford Hall, in the city of Concord, N. H., on Tuesday, June 19, 1877, the President, Dr. A. B. Crosby, in the chair. The attendance was large.

The Association was called to order by the President, after which prayer was offered by Rev. Mr. Campbell, of Franconstown.

The report of the Council was read by Dr. Conn. of Concord, the Secretary. It was considered by sections. Its recommendations to memorialize the State Legislature for the establishment of a State Board of Health, and to memorialize Congress that the Subject Catalogue of the Army Medical Library be printed, were

adopted, as was also a resolution to publish the early reports of the Society.

Certain changes in the manner of choosing officers, after much debate, were postponed for consideration until the meeting of 1878.

The regular working committees for temporary purposes were then appointed.

The hospitalities of the Society were extended to numerous visiting brethren.

PRESIDENT CROSBY then delivered an able oration on "The Ethical Relations of Physician and Patient," and received the thanks of the Society therefor.

DR. COX, of Concord (the Secretary), then read an eminently practical paper on "The Duties of Governments in Respect to Hygienic and Sanitary Provisions."

These, and all other papers subsequently read, were referred to the Publication Committee.

The Society's Annual Dinner took place in the Phoenix Hotel, and was partaken of by seventy-five members and visitors. The speeches were reminiscent, full of gratitude for the past and to the memories of the departed whose labor had made its fame, and also full of hope in a promising future.

At the opening of the afternoon session Prof. Smith, of Peterborough, read the report on Necrology, and sundry necrological papers were read and ordered for publication.

A demonstration of the system of applying the plaster-of-Paris jacket, for the cure of curvature of the spine, was given by President Crosby, the patient being a boy of ten years of age.

DR. FRIED, of Dartmouth, read an able paper on "Therapeutics," dwelling with special emphasis on the qualities of digitalis in the treatment of heart affections.

DR. A. H. CROSBY, of Concord, read a very acceptable essay on "Orthodoxy and Heterodoxy in Medicine."

DR. ALLEN, of White River Junction, read a paper on "The Reduction of Dislocation of the Hip by Manipulation."

Sundry papers were read by their titles and referred to the Publication Committee.

Several district medical society reports were made, and similarly disposed of.

DRS. J. C. EASTMAN, A. F. CARR, and S. G. HILL were appointed a special committee to appear before the Judiciary Committee of the Legislature to oppose "The Medical Tramp" movement before that body.

DR. WHEAT, the Treasurer of the Society, made his annual report. The income during the past year was \$310, and the expenditures \$263. The Bartlett fund in the bank amounted to about \$1,000.

The meeting adjourned at 10 minutes to 9 o'clock, and afterwards attended a reception given by the Concord physicians, at the Phoenix Hotel, which was well attended, and where a large party enjoyed a season of great social enjoyment. A sumptuous supper was served.

#### WEDNESDAY, JUNE 20TH.

On *Wednesday* morning, June 20th, the Society met at a quarter to 9 A.M.

DR. FROST, of Hanover, made a motion, which was carried, that the Board of Censors to be elected should be organized by the appointment of a chairman and secretary, that examination should be had of the time and place of graduation of licentiates, and that their licenses should become subjects of the Society's record. The subject of licensing on diplomas

was taken up, and it was the opinion, and the practice of censors, as it appeared, not to recognize any diploma not granted by an approved college or medical institute.

In accordance with special assignment the Society proceeded at 9 o'clock to make choice of officers for the ensuing year by ballot, with the following results:

*For President*—Dr. Luther M. Knight, of Franklin.

*For Vice-President*—Dr. Alonzo P. Carr, of Goffstown.

Dr. G. P. Conn, of Concord, was re-elected Secretary by an unanimous acclamatory vote.

*For Treasurer*—Dr. Thomas Wheat, of Manchester, by acclamation.

*For Censors*—Drs. Frost, of Hanover; Towle, of Claremont; Hersey and Adams, of Manchester; Cogswell, of Warner; Parsons, of Portsmouth; Barney and Crosby, of Concord; Sanborn, of Franklin; and Gould, of Raymond.

*For Council*—Drs. Gage, of Concord; Weymouth, of Andover; Jarvis, of Claremont; Anthony, of Andrim; Lathrop, of Dover; Fowler, of Bristol; Childs, of Bath; Crittenden, of Plaistow; Wheeler, of Pittsfield; and Adams, of Manchester.

*For Executive Committee*—Dr. W. W. Wilkins, of Manchester; J. W. Parsons, of Portsmouth; and G. W. Carter, of Concord.

PROF. SMITH offered a motion that Dr. Bancroft, of the Asylum for the Insane, be requested to investigate the condition of the insane in the various almshouses and county houses, and report to the Society. This process he explained to be merely an introductory step toward legislative action.

DR. EASTMAN, from the committee appointed to attend the hearing before the Judiciary Committee of the Legislature to oppose the bill to repeal the act against peripatetics calling themselves doctors, which was passed two years ago, and known as "The Medical Tramp Law," made a report in which was embodied the experience of the board appointed to examine these quacks. It was shown that the great majority of applicants were entirely ignorant of even the first principles of medicine.

DR. PARSONS, of Portsmouth, related the particulars of a case of empyema, in which the aspirator was used ninety-three times, which led to a long discussion as to the efficacy of the instrument on chronic cases. Considerable division of opinion subsisted on this point; but it was considered that in all cases it ought to be tried, associated with careful efforts to keep up the constitutional strength of patients, that being, it was feared, somewhat neglected.

DR. PARSONS, of Portsmouth, read a paper descriptive of operations for the reduction of strangulated hernia, which was discussed at some length.

THE PRESIDENT made some very interesting practical remarks on Median Lithotomy.

DR. HILL, of Dover, offered a resolution of thanks to the President.

A final adjournment took place at half-past twelve o'clock.

Annual meeting for 1878 will be in Concord, N. H., the third Tuesday of June.

DIPHTHERIA.—The latest novelty in regard to diphtheria is the supposed influence of drinking-water in causing the disease. To the students of this affection it may be comforting to know that as yet no cases have been found except in the imagination of a rash innovator.

## NEW YORK PATHOLOGICAL SOCIETY.

*Stated Meeting, May 9, 1877.*

DR. A. L. LOOMIS, PRESIDENT PRO TEM., IN THE CHAIR.

DR. MCCREERY, on behalf of the Microscopical Committee, reported the tumor of the breast presented by Dr. Sell at the last meeting to be composite in its nature, being in part made up of alveolar sarcoma, and in part by fibrous tissue.

## THE INTESTINE IN VARICELLA.

DR. PARTRIDGE presented a portion of the large intestine removed from a child who died during an attack of varicella. For the last eight hours of its life it had simple diarrhoea, amounting to five or six passages. With the exception of the right lung, which was the seat of lobular pneumonia, and the large intestine, all the organs appeared to be healthy. In the large intestine there was a large number of small superficial abrasions or excoriations of the epithelial covering, due probably to the frequent passages. Besides this there seemed to be a few spots that had the appearance of flaccid vesicles. Each of these spots was surrounded by capillary hyperæmia. The appearance of the mucous membrane so closely resembled that of the mucous membrane of the mouth, tongue, and palate during the eruption, that it was hardly possible to look upon the occurrence as a coincidence.

Dr. Partridge presented a second specimen, consisting of the ovum discharged from a woman who was six weeks advanced in pregnancy. Previous to her last conception she had three consecutive miscarriages. The exciting cause of the last accident was a bronchial catarrh with troublesome cough.

## REPRODUCTION OF BONE AFTER PARANYCHIA.

DR. POST presented the necrosed distal phalanx of the index finger, the result of a neglected paronychia. The interest of the specimen consisted in its association with an exceedingly rare sequel, viz., the complete reproduction of the bone.

DR. SAYRE had seen several such cases in which the finger bones had been reproduced. The great point in the treatment consisted in allowing the dead bone to remain as long as possible, and until the involucrum was sufficiently firm to preserve the requisite shape and act as an efficient splint.

## VESICAL CALCULUS.

DR. A. B. CROSBY presented two specimens of vesical calculi, removed by median lithotomy. The first patient was fourteen years of age, the signs of calculus having been present for a year. The second patient was seven years of age. The day following the operation on this case the temperature rose rapidly to 103°, but was at once lowered by a warm bath. Both cases did well.

Dr. Crosby presented a third specimen, which was an eye removed by extirpation from a man forty years of age, who had destroyed the organ by falling against a sharp body while intoxicated. After the accident deep-seated inflammation took place, followed by uncontrollable pain and sympathetic irritation of the other eye.

## A QUESTION IN DIAGNOSIS.

DR. LOOMIS exhibited a specimen removed from a Cuban boy thirteen years old, who was admitted to Bellevue Hospital on the ninth of April. No family history could be obtained. The personal history was incomplete. It was stated by his friends that he had been suffering for a year past with constant

pain in his head. This pain had been frontal in character for the most part, but at times extended all over the head. It was most severe during the day, and was increased by excitement. During this time he had lost flesh and strength. Three months before his admission the pain was much more severe, and was constant. This was attended with some nausea and vomiting, and some difficulty in passing water. Two months before admission he became totally blind, whether suddenly or not could not be ascertained. He would also have attacks of hicough which would last three or four hours at a time. At that time it was also noticed that he had a difficulty in his speech. His answers to questions were slow but not imperfect. His intellect was clear. When admitted he was unable to stand or even to sit up in bed. If he was placed upon his feet, his legs gave way and he fell to the floor. If he was raised in bed, he would slide down on his back, with his head flexed to the left and his left hand carried up to the back of his head. His pulse was 118, and feeble; temperature, 98½°. Pupils were widely dilated, did not respond to the light, and he was evidently totally blind. There was total deafness on right side, while on the left side the tick of the watch could not be heard beyond an inch. Tongue was flexed to the right when protruded. Slight facial paralysis on right side. Less power in grasp of right hand than in the left, but no marked paralysis. About the only thing he complained of was pain in the head. The sense of taste was good, but that of smell seemed to be somewhat limited.

The diagnosis made before the class was: probable tumor of the brain, perhaps meningitis, possibly both tumor and meningitis. The second day after admission he passed into coma, in which condition he remained for twelve hours, when consciousness returned. There were a number of times on which he passed into this semi-conscious condition, but on the 23d of April the coma became deeper than usual, and he died.

At the autopsy, the dura mater was found adherent to the posterior portion of the skull and cerebellum. In other words, the two surfaces of the arachnoid, the dura mater, was adherent to the brain, and there were evidences of basilar meningitis. There was no tumor of the brain at any point. The lateral ventricles were distended with serum, the optic thalami were flattened, as were also those convolutions in the neighborhood of those places where the distention was the greatest. Scattered over that portion of the arachnoid that was attached to the dura mater, were a number of smooth bodies having all the characteristics of miliary tubercles. The latter were also found upon the surfaces of both pleura, also in the spleen and liver. It was then a case of basilar meningitis of the tubercular variety. The question suggested by this case was whether the symptoms referred to as belonging to cerebral tumors did not in reality, for the most part, at least, belong to those of the ordinary meningitis, with which such tumors were so invariably associated.

DR. CARPENTER remarked that when the specimen was fresh the miliary tubercles were apparent for a considerable distance in the substance of the cerebellum itself. Some of the granular bodies were found in the kidney, but none in the fissure of Sylvius.

DR. MASON presented the astragalus and portion of the external malleolus, which he removed by operation from a case of congenital talipes equino-varus.

The patient was a woman aged 20 years, in whom the deformity of both feet was congenital. She was able to walk for a mile at a time, although with much difficulty, as the weight of the body was on the outer and dorsal surfaces of the foot. The patient had been

under the care of Dr. Sayre, who divided both plantar fascia, with, however, no good effect. Dr. Sayre kindly handed over the case to Dr. M., and the patient entered his service at Roosevelt Hospital, March 29.

Dr. M., in studying the case, conceived the possibility of removing the cuboid bone and then bringing the foot in position. Dr. Post, on examining the case, suggested the propriety of removing the astragalus instead, thereby preserving the arch of the foot. This operation was accordingly done, April 2d, upon the left foot. An incision was made nearly midway between the malleoli, the tendons and vessels being carefully pushed to one side. It was noticed that the extensor brevis was remarkably well developed. The astragalus was removed with great difficulty by the careful use of the scalpel and scissors. An attempt was made to straighten the foot, when it was discovered that the external malleolus impinged in such a manner upon the outer surface of the os calcis, that the foot could not be brought to a right angle. The external malleolus was accordingly cut off. It was even then found that the foot could not be brought in position until the tendo achillis was divided. The limb was placed in plaster-of-Paris, with a large fenestrum opposite the wound, and the patient put in bed.

Although she seemed in excellent condition, some spots of ecchymosis appeared upon the right foot. Similar spots were noticed upon the right foot the following day, following hypodermic injections. On the third day she had an attack of severe stomatitis, coincident with which the tissues about the foot were noticed to be sloughy. The large bursa on the foot sloughed, leaving bare almost the entire dorsum. The toes preserved their vitality. On the 5th of April, the splint was removed and the limb was placed in a fracture-box. At that time there was noticed a large slough behind the internal malleolus, and altogether her condition was very unfavorable to recovery.

Early on the morning of April 15, a copious secondary hemorrhage occurred evidently from the posterior tibial artery. Amputation of the leg was performed on the afternoon of the 15th. Everything promised fairly after the operation until the 3d of May, when for some utterly unaccountable reason, she lost her appetite and spirits, and died May 8th. Two or three days before her death she suffered severely from an abscess of her index finger. Although the case terminated so unfortunately, Dr. Mason declared that the operation was a feasible one, and that he should be ready to perform it again upon a patient in a proper physical condition.

When studying up the case, Dr. Mason was not aware that the operation had ever been performed before. Dr. Sayre wrote to Dr. Levis of Philadelphia, regarding this point, and Dr. L. referred the question to Dr. John Ashhurst, Jr., of Philadelphia. That gentleman made the following reply:

"2,000 W. DELANCEY PLACE, April 9, 1877.

"MY DEAR DOCTOR:—I know of but one case in which the *astragalus* has been excised for talipes varus, that being a case in which Mr. Leard, of Manchester, did the operation on both feet of a child. The case was published in the *British Medical Journal* for October 19, 1872, and is copied in the *New Sydenham Society's Biennial Retrospect* for 1871-72, p. 226.

"Excision of the cuboid bone for varus, originally suggested by Dr. Little, was first performed by Mr. Jolly; an account of the case is given by Mr. Adams in his "Treatise on Club Foot," second edition, p. 250. This operation has since been repeated by Mr. R. Davy, of the Westminster Hospital, but I have

mislaid the reference to his cases; and quite recently Mr. Davies-Colley, of Guy's Hospital, has excised the cuboid, with parts of the *astragalus*, *scaphoid*, *calcaneum*, *cuneiformis*, and the *cartilages* of the outer *metatarsal*. This case was reported to the Royal Medical-Chirurgical Society, and was published in the *Lancet*, for Oct. 14, and the *Medical Times and Gazette*, for Oct. 21, 1876.

"I do not know of any case in which the *scaphoid* alone has been excised for club-foot.

"Very truly and respectfully,

"JOHN ASHURST, JR."

DR. CROSBY said that he was much struck with the result of the case as connected with similar ones which come from the country to be operated upon in our large hospitals. Her condition would appear to show that she had not become acclimated to the hospital. It was a question with him whether it was not better to operate upon such cases before they had a chance to break down.

DR. SAYRE remarked that the mental condition of the patient was very unfavorable to recovery, she having left her home against the will of her parents, to have the operation performed.

#### PERICARDITIS IN YOUNG CHILD.

DR. LEWIS SMITH presented the lungs of an infant aged four and a half months, who died at the New York Foundling Asylum, after a sickness of six days. When Dr. Smith saw the patient forty-eight hours before death, it was apparently moribund. The lips were slightly livid, the respiration very much accelerated; pulse feeble and frequent; temperature  $101\frac{1}{2}$ . Bronchial respiration was heard on both sides of the chest, and double pneumonia was diagnosed. At the autopsy, instead of the double pneumonia, there was found purulent pericarditis. The left lung was healthy, but over its anterior portion there was pleurisy with effusion, due to the extension of the inflammation from the pericardium. On the opposite side there was a pneumonia limited to the third of the upper lobe. The point of interest was, the extreme rarity of pericarditis in a child of that age.

#### ARMY NEWS.

*Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from June 24 to June 30, 1877.*

BAILEY, J. C., Surgeon. Assigned to duty as Post Surgeon at Benicia Arsenal, Cal. S. O. 66, Division of the Pacific and Dept. of California, June 15, 1877.

BACHE, D., Surgeon. In addition to his present duties, to attend the sick at Alcatraz Island, California, S. O. 68, C. S., Division of the Pacific and Dept. of California.

MIDDLETON, J. V. D., Surgeon. Assigned to duty at Fort Schuyler, New York harbor. S. O. 139, C. S., Division of the Atlantic. And granted leave of absence for two months. S. O. 140, Division of the Atlantic, June 26, 1877.

WOODHULL, A. A., Surgeon. Relieved from duty at Alcatraz Island, California, and assigned to temporary duty at Camp Halleck, Nevada. S. O. 68, C. S., Division of the Pacific and Dept. of California.

VICKERY, R. S., Ass't Surgeon. Assigned to temporary duty at Fort Schuyler, New York harbor. S. O. 142, Division of the Atlantic, June 28, 1877.

DE WITT, C., Ass't Surgeon. Assigned to tempo-

rary duty at Omaha Barracks, Nebraska. S. O. 87, Dept. of the Platte, June 26, 1877.

SEMIG, B. G., Ass't Surgeon. Assigned to duty as Post Surgeon at Camp Bidwell, California. S. O. 66, C. S., Division of the Pacific and Dept. of California.

NEWLANDS, W. L., Ass't Surgeon. To report to Major George B. Sanford, 1st Cavalry, for duty with his command. S. O. 68, C. S., Division of the Pacific and Dept. of California.

## New Instruments.

### A RESPIRATORY BRACE.

DR. GEO. F. FRENCH, of Portland, Me., has devised (*Boston Medical and Surgical Journal*) a very useful appliance for the relief of orthopnoea. It consists, as will be seen from the accompanying cuts (Figs. 1 and 2), of a cross bar from the extremities of which hang two loops of strong elastic webbing for the support of the shoulders. The broad band encircling the head is steadied by guys stretching across on both sides to the upright elastic supports. The apparatus is suspended by a pulley or ring from the ceiling. Fig. 1

Fig. 1.

represents a patient resting with the brace applied under the shoulders. Whenever, from the weight or helplessness of the patient, or from the tedious duration of the case, the circulation in the arm is impeded, the support should be afforded by the elbows, as in Fig. 2, in which the entire pressure comes upon the outside of the forearm. Usually, however, the degree of pressure under the arms requisite to sustain a person who is sitting is insufficient to interfere with the circulation. The utility of the apparatus can hardly be questioned. The thorax being slung as it were by the arm-pits, and the head properly steadied, muscular fatigue is prevented, the voluntary and involuntary respiratory muscles have the best possible chance to act, and the patient is supported in an easy sitting position for sleep. Aside from this the apparatus can

be adapted to every case in which it is necessary to afford an effectual and comfortable sitting position

Fig. 2.

and relieve the upper portion of the body from the weight of the shoulders and head.

## Medical Items and News.

CONTAGIOUS DISEASES.—Comparative statement of cases of Contagious Disease reported to the Sanitary Bureau, Health Department, for the two weeks ending July 7, 1877.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-Spinal Meningitis.	Measles.	Diphtheria.	Small-pox.
June 30.....	0	5	88	0	56	32	2
July 7.....	0	4	70	2	31	42	5

LONDON CHARITIES.—Several of the large medical charities in London are in great want of funds. The *Lancet* advocates their permanent endowment.

SMALL-POX.—The study of the recent small-pox epidemic in Great Britain affords additional corroboration of the fact that epidemics decline on the advent of warm summer weather.

TAYUYA A SPECIFIC FOR SYPHILIS.—A resident of Milan, by the name of Ubcini, is said to have met with a tribe in Brazil who have been peculiarly afflicted by syphilis. They have been successfully employing a plant of the family cucurbitacea (*Dermophylla pendulina*), which grows in the wilds of Brazil. One gramme of the alcoholic extract is given by subcutaneous injection. A complete cure and no return is promised for those who use the drug.

NURSE-TRAINING IN FRANCE.—A school for training nurses has just been started in Paris under the auspices of Dr. Duchaussoy. The establishment is under the patronage of a board of influential ladies.

## Original Communications.

## ON CERTAIN POINTS RELATING TO THE NATURE AND TREATMENT OF LUPUS.\*

By HENRY G. PIFFARD, M.D.,

PROF. OF DERMATOLOGY IN UNIVERSITY OF CITY OF NEW YORK, SURGEON TO CHARITY HOSPITAL, ETC.

For the purposes of this paper, we will find it convenient to use the term lupus as a general designation for several morbid conditions that present certain features in common. The name, however, is one not altogether desirable, as its signification is not well defined, different authors including under it several affections which differ in aspect, in histological characteristics, in course, and in prognosis. Rejecting in advance all affections of a syphilitic nature, we confine the term to certain cutaneous lesions that present a few important common peculiarities. To these affections the Germans have given the names of *Lupus Erythematous* and *Lupus Vulgaris*, and the French the collective title of *Scrofulides*. The latter designation is the one that we prefer, believing, in common with most writers, that these cutaneous lesions are usually, if not always, dependent upon the somewhat undefined and vague condition of ill-nutrition to which the name *scrofula* or *struma* is applied. As the object of the present paper is practical rather than theoretical, we will not attempt to discuss the questions of etiology and nomenclature that under other circumstances might prove interesting.

The principal common features of the different varieties of lupus are: absence of pain or itching, extreme chronicity, ultimate destruction of all the tissues invaded, and difficulty of cure.

As a rule, the most extensive lesions cause little inconvenience to the patients, except by the disfigurements that they produce.

Their chronicity is proverbial. An erysipelas, or an eczema may cover in twenty-four hours an area that it may take as many years for lupus to involve. This is well illustrated by the photograph of F. W., in whom the disease commenced in 1854 (twenty-three years ago), and has been constantly present and slowly advancing up to the date when the photograph was taken (March, 1877). As a rule, however, the progress of the disease is more rapid, but never to the degree exhibited by simple inflammation, by syphilis, or by true malignant processes.

The ordinary clinical features of lupus are familiar to most, are well described in many treatises, and have recently been considered with care, and I believe with substantial accuracy, by myself. Lengthened detail concerning them would therefore be out of place at the present time, and we will pass to the consideration of certain histological points.

If we remove portions of lupus tissue, and harden, slice, and stain them with carmine, we will find on microscopical examination of the stained slices very notable deviations from the appearances presented by the normal tissues. The prevailing feature in all cases is an infiltration of small round cells, resembling the colorless corpuscles of the blood. This infiltration may be simply diffuse, or diffuse with the addition of certain other cells of peculiar appearance. These are many times larger than the small round cells, are

polymucleated, and on account of their size have received the name of *giant-cells*. Lastly, the small round cells, instead of being diffusely infiltrated, are collected into certain little clumps or heaps. These three principal histological types found in lupus correspond to three pretty distinctly marked clinical varieties, which differ widely in their appearance, course, and prognosis.

In comparing the microscopical appearances with the cases from which the specimens are derived, we find: First, that the diffuse infiltration corresponds to the superficial forms of lupus, in which ulceration never occurs; second, that the infiltration associated with giant-cells occurs in the deeper forms with ulceration and destruction of the entire thickness of the skin; and thirdly, that the "cell-heaps" are met with in cases that invade the deeper tissues beneath the skin. The diffuse, small, round cell-infiltration met with in superficial lupus cannot be distinguished microscopically from small cell-infiltrations in other affections, for we may find identical appearances in syphilis, and even in simple inflammation. In the deeper cutaneous lupus, characterized by the diffuse infiltration *plus* giant-cells, we again find nothing peculiar, as giant-cells are met with in many scrofulous hyperplasiae, in syphilis,\* and even in normal infantile bone-marrow. The cell-heaps, however, that we find in the deeply ulcerating form are peculiar to lupus, not having been found elsewhere, so far as I am aware. From this we see that there is but a single histological appearance that can with propriety be regarded as peculiar, and this is met with in but a small minority of cases.

To what then does lupus owe its destructive features? It is not to the size or shape of its cells or the manner of their distribution, for in these respects we cannot, as a rule, discover anything not found in other diseases. We must turn, then, from the microscope, we must look beyond the mere morphology of the cells, and endeavor to penetrate their chemical and vital peculiarities.

When we examine the subject from this point of view, and compare lupus with certain other cutaneous affections, we immediately detect important contrasts. A simple inflammatory infiltration may undergo resolution, and disappear in a few days, and leave behind no mark or sign of its previous presence. A syphilitic infiltration may also resolve and disappear in a few weeks, and leave little more than a temporary stain to mark its site. A lupus infiltration in like manner undergoes resolution, but it is only after long months or years; and when this is finally accomplished a scar corresponding to the extent of the lesion is the inevitable result. We see, then, that the important peculiarity of lupus is the extreme viability of its cells.

Another peculiarity is its gradual extension and involvement of new regions by an apparently infective process, similar to, but less in degree than that manifested by cancer. In other words, lupus is an affection that presents a certain degree of malignity, varying in different cases, and always less marked than in true cancer. This infective quality is evidenced by the fact that, if a patch of lupus be incompletely destroyed, the disease will most certainly return.

The infiltration in lupus, after it has existed for an indefinite period, ultimately resolves, probably by fatty degeneration and absorption of its cells. This, however, only occurs after the lapse of years, and

\* Read before the Medical Society of the State of New York, June, 1877.

\* COLOMIATTI, *Giornal d. Med. Ven. della Pelle*, An. x., 1875, p. 324. BROWICZ, *Centrab. f. die Med. Wissch.* No. 19. 1877.

while resolution is in progress at points first attacked, there is a gradual progression outward, involving the adjacent regions.

A consideration of these two points, namely, the extreme viability of the cells and their infective quality, gives us a clue to appropriate treatment. The indication is clearly to remove the infiltration as soon as possible, and to remove it thoroughly; to destroy, not nine-tenths or ninety-nine hundredths of the lupous cells, but *all* of them. How this may best be done will now be considered.

*Treatment.*—Unfortunately we possess no medicinal agents capable of exerting a specific or elective action on the lupous process. There is no question, however, but that mercury, iodine, iodide of potassium, and cod-liver oil exert a beneficial influence. They are both notable resolvents and powerful antistrumics. Phosphorus is another energetic agent capable of influencing the disease. It is, however, a two-edged sword, and one that is to be handled with great circumspection. The principal physiological, or rather pathogenetic, action of phosphorus is the production of fatty degeneration. As morbid growths possess less vitality than normal tissues, it is possible that the phosphorus induces fatty degeneration of the lupous cells, thus favoring absorption when given in doses that are insufficient to produce a like result in healthy organs. If this explanation is correct, and it is the one which seems to me most plausible, it is manifestly proper to avail ourselves of the advantages that it presents, at the same time bearing in mind the possibility that, while we are curing the lupus, we may also be killing the patient. We have seen brilliant cures (?) of cutaneous affections accomplished with large doses of mercury, iodide of potassium, and arsenic, but at the expense of the future health of the patient, and there are indications that phosphorus is at the present time being used to excess. While, then, we acknowledge the power of phosphorus, we cannot unreservedly recommend its use.

The above mentioned comprise the internal remedies most useful in lupus, but we cannot depend upon them alone, as they will, if unaided, rarely if ever effect a cure. Our main reliance is upon external treatment.

The various methods at present in vogue fall into three categories. The effort is made either to produce absorption of the lupous cells, to remove them mechanically, or to destroy them *in situ*. The first of these methods is the oldest, and is the one that has been most frequently practised. Absorption of the infiltration, when limited, may sometimes be procured by strong alkaline applications, *e.g.*, Sapo viridis, liq. potasse, or stronger solutions of caustic potash, or by acids, such as the glacial acetic and mono-chloroacetic acids. The biniodide of mercury in ointment is also employed for the same purpose. As the details for the employment of these agents are given in the text-books, their special consideration at this time is unnecessary. This method, whatever agent is employed, is tedious, painful, and uncertain.

The mechanical removal of the cells is a plan that has recently come in vogue. It is effected by means of a small sharp-edged spoon (spoon exhibited), with which the infiltration is scraped out. The morbid tissue yields to the scraper more readily than the healthy, and a very considerable portion of the infiltration can be thus removed mechanically. If all of it—that is, every cell—could be thus scraped out, this method would be a simple and a good one. Unfortunately, however, this can rarely be accomplished, and in the great majority of instances relapse occurs.

The result is somewhat better if, after the scraping, pure chloride of zinc is applied to the denuded surface, but, even after this, relapse is not infrequent. The only mechanical means that can be relied on is complete excision, and, if any doubt exists as to the thoroughness of the operation, the chloride of zinc should also be applied to the wound. Excision, when practicable, is certainly the most reliable and in every way best method of treatment. In the majority of cases, however, it is not practicable, and consequently other means must be employed.

The destruction of the cells *in situ* may be accomplished in several ways. First, by boring into the diseased tissues with the solid nitrate of silver in pencil-form or fused upon a probe; second, by arsenical pastes; third, by the actual cautery. The first is well adapted to lesions of limited extent, and is often successful. The arsenical treatment is likewise efficient, and if properly performed it is perfectly safe, but is exceedingly painful. It is only adapted to small patches, or, if the patch is large, to successive portions. The arsenical and nitrate of silver methods have been often described, and are, or should be, well known. In the actual cautery we also possess an efficient agent. If the lesion is very superficial a thorough cauterization at a *white* heat will be sufficient to effect a cure, and will leave a very good scar. If the lesion is somewhat deeper, a less degree of heat, say a red heat, will penetrate more deeply, and destroy the lesion, but the ulcer left by the fall of the slough will be slower in healing, and the cicatrix will be more retractile—a very important consideration when the disease is situated upon the face. That this method will not always succeed is evident from the case of F. W., to whose face three applications of the white-hot cautery were made during a period of two months. A portion of the lesion has been destroyed, but the lower part of it still exists. This is well shown in the photographs.

Of all the methods mentioned, it might be expected that we would find at least one that could be generally relied upon. This, however, is not the case, and if we remember that a permanent cure can only be expected by getting rid of every lupous cell, and that we must accomplish this without inflicting too great injury upon the adjacent healthy parts, we can readily understand the difficulties to be encountered.

A somewhat varied experience has finally led me to a method, or rather combination of methods, that can, I think, be relied upon in almost every case. The plan that I would recommend is to *thoroughly scrape out as much of the lesion as possible, and then to cauterize the floor and edges of the wound with the actual cautery at a white heat.*

The following cases treated by mechanical measures illustrate some of the points alluded to in this paper:

I.—J. S.; lupus of eight years' standing. Principal lesion in region of left eye, several other foci of disease. In the early stage of the disease caustics were applied with relapse and aggravation; in an advanced stage excision and cauterization with pure carbolic acid; relapse; two tubercles on chin excised (histological character, "cell-heaps"), without relapse; one tubercle on forehead scraped and solar cautery, without relapse. Ultimate termination, death by phthisis pulmonalis. (Illustrated by five photographs.)

II.—McG.; lupus on the side of the nose; excised; no relapse. (Illustrated by diagram.)

III.—O'C.; lupus of nose; excision (histological character, diffuse infiltration, with giant-cells); relapse; relapse treated with pure chloride of zinc; no relapse at end of two months. (Two diagrams.)

IV.—J. A.; lupus of temple; excision (histological character, cell-heaps); no relapse at end of eighteen months. (Illustrated by diagram.)

V.—R. L.; lupus of face, fifteen years' duration; three foci of disease; one excised (cell-heaps); no relapse; the other two scraped, and chloride of zinc applied; in both instances relapse. Later, one of these was scraped and the actual cautery applied without relapse; the other was excised and the actual cautery applied without relapse. A fourth lesion, which had appeared subsequent to the first operations, was scraped and the nitrate of zinc applied. This relapsed and the ultimate termination of the case was death by phthisis. (Illustrated by three diagrams.)

VI.—Lupus of the scalp; scraped, followed by relapse; later, scraped and actual cautery; no relapse.

VII.—E. S.; lupus on cheek; scraped and chloride of zinc; relapse; again scraped and actual cautery; no relapse.

VIII.—L. W.; lupus of penis; four foci; one excised (histological character, diffuse infiltration); no relapse; three cauterized with actual cautery. In two no relapse; in one relapse; recauterized; no relapse.

IX.—F. W.; lupus of twenty-three years' standing; three applications of white-hot cautery; partly cured; subsequently scraping and actual cautery; still under treatment. (Two photographs.)

X.—T. G.; lupus of nose and upper lip, three years' standing; scraped and cauterized in sections; no relapse. (Two photographs.)

The comparative efficiency of the various methods of mechanical treatment employed in the foregoing cases may be summarized as follows:

	Successful.	Unsuccessful.
Scraping and chloride of zinc . . .	0	4
Chloride of zinc (very small and superficial lesion) . . . . .	1	0
Scraping and nitrate of zinc . . . .	0	1
Actual cautery . . . . .	4	2
Excision . . . . .	6	2
Excision and actual cautery . . . .	1	0
Scraping and actual cautery . . . .	4	0

‡A number of cases (of which I have not kept notes) treated by some of the above methods, and several cases in which the ultimate result of treatment is unknown, are not referred to. It will be seen, however, that success is in direct proportion to the thoroughness of the operation, and that our effort should be to remove every lupous cell. This is to be effected by excision when practicable. In other cases scraping, followed by the actual cautery at a *white heat*, gives us the best assurance of success.

**A FEW REMARKS ON, AND CASES OF SUCCESSFUL CALCIFICATION OF TUBERCULOSIS OF THE LUNGS.**

By C. BOTH, M.D.,  
NEW YORK.

In order to meet the request of various medical men, in different parts of the country, to describe the mechanism of my plan of treatment, I would say that the mechanical treatment for *clearing* the lungs and the *re-establishment* of vesicular respiration consists of three different exercises, which follow each other as the strength of the patient permits. I. The patient is placed in an erect position, with both arms extended, horizontally, on the level with the shoulders. In this position he advances towards a corner of a room, when the hands are placed flat upon the wall, the body is

moved slowly forward into the angle, the hands gliding upon the wall. The arms must not be bent, and the spine must be held erect. The actual contact of the patient's face with the corner is hardly ever accomplished on the first attempt; however, he is urged to get as close as possible. He is then told to bend his elbow-joints, and to pull himself slowly back again by the power of the pectoral muscles. The hands to remain on the spot where they were. This exercise stretches the chest very much across the clavicles. Patients are told to do this from six to twelve times per day. Muscular pain across the chest is the next consequence. In about a month the patient should have gained sufficient strength to begin the exercise No. II. This consists in the same movement, with the body in a horizontal position. The patient lets the body *slowly* sink towards the floor, as far as his strength permits. The hands rest upon two chairs placed at a distance of four to five feet, and secured. The whole weight of the body rests upon his two hands and his toes. He having approached the floor as near as he can, is then told to pull himself up again as slowly as he sank. This is a very difficult exercise and makes the muscles tremble; involuntary deep inspirations follow it immediately. In about three to five months the third and last exercise is commenced. The patient is placed in the middle of a room in an erect position. *One* arm is lifted at the time, as in exercise No. I. This horizontally stretched out arm is reversed in a circle around its axis as if no body was in the way. Of course, when the arm comes in front of the chest, the spine has to be bent backward so as to make room for the arm to revolve. This exercise is very difficult and affects every muscle in the body. In all these exercises the knees must never be bent, the epigastric region not allowed to incline forward, and the respiration not interrupted at any moment. The last exercise gives the finishing touch to the lungs, and a patient advanced to do it is considered an absolutely curable case. The first is generally dropped as soon as No. II. is learned. These exercises should raise the pulse momentarily about ten beats and no more; it must return to its previous height after a few minutes of rest. Although a healthy man cannot do these exercises well on the first attempt, consumptives learn to do them with the greatest ease and comfort. The purpose is to clear the bronchi and alveoli of phlegm, so as to induce the meshes of the elastic tissue to open and shut again. In other words, recreate respiration in the diseased portions.

I have been urged to state some cases cured by my method. I am well aware that in a disease which is generally voted to be incurable there is a great difficulty in convincing the skeptical, and that there is always a doubt about the diagnosis and a suspicion that imagination is overactive. Finally, it may be said that such cases might have recovered by accident and not by any particular plan of treatment. For these reasons I shall simply mention a few selected ones which have been seen by other medical men, before, during, or after treatment, and which seem to me as excluding mere accident.

Mr. F. L. Lay, an artist, consulted me in the winter 1857-58 in regard to various hemorrhages from which he had been suffering, and a continued cough of several years' standing. In my opinion he had tuberculosis in both apices. After thirteen months' treatment I discharged him as cured. He remained well until the spring of 1864, when he consulted me about a very disturbed digestion, with severe headache. This headache resisted all treatment, both by me as well as other physicians, until after the fifth month it affected his

sensorium. He then began to fail rapidly. Severe cough with abundant expectoration returned. Pulse very low. Dr. Cabot, surgeon to the Massachusetts General Hospital, saw him in September, considering him a hopeless case. So did I. He was reduced to a skeleton; delirious for nearly two months. There seemed to be an almost entire paralysis of the sympathetic. He finally completely recovered, and is living to-day in Frankfort-on-the-Main. I presented this case several times before the Gynecological Society of Boston, and Dr. H. R. Storer's classes. I supposed this last affection to have been a secondary tubercular meningitis. The dullness of percussion in the apices has remained the same for twenty years. This patient is not only perfectly well, but remarkably strong.

Mr. N. P. Merritt, a clothing merchant of Boston, came to me in 1861, after having been obliged to discontinue business for five years. After six months under my method of treatment he was able to resume business, and gave up treatment after nine months, against my wishes. I lost sight of him until February, 1864, when I found him much reduced from a four months' continuing diarrhoea, during which time he was under the care of Drs. Read and Henry I. Bowditch. I gave him the pure juice of twenty lemons, after which he had a large watery discharge containing pieces of mucous membrane, decayed follicles, and pus. After that the diarrhoea ceased, but he died of nervous exhaustion eighteen days afterwards. The autopsy revealed fifteen encapsulated abscesses in his lungs, from the size of a pea to that of a walnut. The mesenteric glands, being secondarily affected, caused his diarrhoea and death. Specimens of these lungs are in my possession, exhibiting to the naked eye the re-entering of air in between the affected lung portions.

Mr. W. S. Craibe, head clerk of the St. Denis Hotel, New York, came to me in December, 1866. Prof. Willard Parker had sent him home for acute tuberculosis; and his family physician, in consultation with Dr. Calvin Ellis, of Boston, prognosticated his death inside of three months. On the 1st of April, 1867, he re-entered upon his duties in the St. Denis Hotel. Dr. W. Parker, to whom I sent him for re-examination, found his lungs in the same condition. Dr. Krackowizer pronounced him, after careful examination, a case of real tuberculosis. In September of 1867 Dr. Krackowizer admitted that he was much better, but could never recover so far as to be taken by a life insurance company. In February, 1868, I had him examined in the New York Mutual, the Germania, and, I believe, the Globe Insurance Companies; all three were willing to accept him as a fair risk. He got married in 1870, and died of small-pox in Boston in 1872, having been on duty till suddenly attacked by small-pox. He was buried ere I heard of his death.

Mr. Joseph Hoizmeister, a medical student of Vienna, Austria, came to Boston in 1868 for treatment. Had been a patient of Dr. Luzinsky, in consultation with Profs. Rollett and Löhl, of Vienna, Dr. v. Hansen, at Gleichenberg, and Prof. Dr. Helfreich, of the Würzburg Hospital, all of whom had advised him to live in Madeira. Dr. Lothar Voss, then in New York, examined him while here. After seven months he returned to Germany so much improved that his physicians were surprised. He resumed his studies. In 1870 he went on a hunting expedition, contracted acute peritonitis, and died in two weeks. I was informed that upon autopsy his lungs had been found completely calcified. Whether this peritonitis was a primary or a secondary affection I have not been able to ascertain, but from the suddenness of attack I sup-

pose it to have been independent of his previous tubercular affection.

Mr. George Smith, of Auburndale, Mass., a merchant of Boston, came to me in April, 1872, in a very precarious condition. Besides many other physicians, had been a patient of Dr. H. I. Bowditch. Pulse 120 to 130; besides his lungs denoting the usual dullness, crepitation, and catarrh, his abdomen was very sensitive, and there had been expectoration of pus for over two months. In 1874, after having resumed his business for over a year, and being able to row a boat containing three persons for ten miles, I sent him to Dr. Bowditch for examination. Dr. B. wrote me as follows: "As the patient has new signs of trouble in one lung which did not exist (according to my record) when I saw him, I must decline considering him cured." Mr. Smith is in business to-day, and resides in Auburndale, apparently in as good health as most other people.

Mr. B. I. Baker, 47 Wall Street, New York, became my patient in 1868. Had been examined by Drs. Bradley and T. F. Allen, of New York, and Dr. Hadden, of Jersey City. The Homœopathic Life Insurance Company refused to insure his life for \$1,000 in 1868. He is now insured in the New York Mutual, his policy, dated May, 1874, mentioning him as a first-class risk.

Although ladies generally present more difficulty for treatment than men, by being fretful and whimsical, the quickest records of recovery are among them. Mrs. H. T. Ch., wife of a Boston importer, became my patient for lung disease in March, 1862, and was discharged as well in July of the same year. She is well to-day. She lost most all her family by consumption. Dr. Langmaid, of Boston, is well acquainted with the case, as well as the tendency of her family to consumption.

Mrs. R., wife of a lawyer in Rochester, New York, was referred to me by Dr. Knichling on the 2d of July, 1873, and discharged as cured on the 18th of August, the next month. She is well yet. Both her physician as well as her family had been much alarmed about her.

Mrs. W., wife of a wealthy farmer, was sent to me by Dr. P. G. Clark, of Rochester, New York. She made a very quick recovery in three months, and is well to-day, as far as I know.

In mentioning these cases I have purposely left out my own opinions and diagnosis, simply mentioning such physicians who happen to know the cases for reference. Any one doubting the reality of them can easily ascertain the facts.

I am sorry to have omitted measuring the chests of my patients before and after treatment, of which I was reminded by Prof. Lewis A. Sayre. This never occurred to me, as the internal structure of the lungs occupied my thoughts much more than external changes, but I know that the form of the thorax changes in all of them. I omit measuring the temperature, because I consider it worthless; it is too changeable, does not help me in regard to the calculation on the changes of the blood causing it, and is apt to trouble and disturb patients unnecessarily. I admit that such is useful in acute affections of serious nature, but in chronic diseases, especially consumption, it is without purpose. If the pulse and temperature in consumptives do not fall to normality in a certain given time, I arrest all treatment, and let the patients enjoy their last days in peace, simply preventing suffocation. All cases which I have lost have died of nervous exhaustion, the sympathetic failing to help; without struggle or painful sensation, not generally even being aware of the approach of death.

My entire attention in curable cases is to the *digestion*, the expectoration, and the *pulse*, which latter must be as regular as a chronometer. The expectoration is at first of a bronchial character; afterwards it has a wormy appearance, with grape-like bunches, oftentimes tinted with blood. This shows the clearing of the bronchioles and air-vesicles, and is very favorable. From the fact that no lung can heal until previously cleared of phlegm and pus, and accessible to air, it is not so much the more or less affected lung which decides a favorable or unfavorable prognosis, but the power of the sympathetic nerve, without which nothing can be accomplished. It is the same as with recovery from capital surgical operations. A case now under treatment may illustrate this: Mr. H., a New York merchant, became my patient in October, 1876. Has been lung sick for ten years; lost a brother and a sister with consumption; has been examined by Drs. A. Flint, Alonzo Clark, and is a regular patient of Dr. Tucker, in Twenty-sixth Street, New York. Right upper lobe presented a cavity two by four inches; right lung completely filled with tubercles; right pleura filled four inches with exudation; left upper lobe tubercular; left lower the best one in the chest. Has been through the routine of all medication, climates, etc., for the last ten years. Had serious fever during the summer of 1876, in Colorado. Felt better after returning. Pulse high and fluctuating—as high as 124; looked remarkably well in the face, considering the serious affection of his lungs. This patient, with the exception of three days, when I ordered him to bed, has been out every day and evening during the winter, without catching a single "cold;" lost at first four pounds, which he has regained now; the exudation in the pleura is gone; left lung free; right lung clearing slowly, but surely; the cavity is reduced more than half its former size; pulse below 70 in the morning.

In spite of his very much diseased lungs and cavity, this patient has steadily improved, and I expect to let him do business in the fall, and discharge him about the 1st of January, 1878. If such a recovery is accidental, it is certainly a very peculiar complication of happy accidents.

In regard to the difficulty regarding prognosis, the following two cases may be interesting: Mr. B., a merchant of 51 New Street, New York, became my patient in October, 1876. Mr. G., a member of the New York Stock Exchange, on the 3d of January, 1877. The extent of the affected lungs were alike in both cases. One lost a brother of consumption in Madeira, in 1875; the other a sister, in the same year. Dull percussion in both apices to third rib; moist crepitation; destruction of tissue in left upper lobe. Muscles in both lax and powerless. Digestion in both completely out of order. Only the pulse showed a marked difference; in the first case, the pulse was 135; in the latter, only 84—also the expectoration varied; in the one, appearing of a more fibrinous, the other a more albuminous nature. The first case, with a pulse of 135, left New York on the 24th of May for a pleasure trip, and is expected home in October, to resume business. The sympathetic nerve in the other refused. One morning in April he smoked a cigar, after which he fell asleep and did not awake again. To all appearances the prognosis was even in these cases. In fact it was more favorable in the second case; but the nerve in the first held out long enough, while in the second it did not. This difference in the nervous power of patients used to perplex me much years ago; and to-day I have not yet discovered any means to ascertain this power, except by testing the case for at least two months. While the curable cases advance

steadily, the lost ones come a to dead stop, when they visibly fail from nervous exhaustion.

The great importance of the sympathetic can best be observed in digestion. The slightest mistake in the diet, in the selecting or missing of certain food, a mental disturbance, is sufficient to upset a case for hours, sometimes for days. The cough at once becomes tight, and the pulse rises. If things are not rectified at once, fever will appear soon after, with night-sweats following.

With these necessarily roughly sketched illustrations, I hope to meet the request of those who have addressed me in regard to the matter. Their insufficiency rests in the difficulty to *tell* what should properly be *shown*.

Astonishing to me is the yet predominating idea that chronic lung affections are absolutely incurable. From a historic point of view this is excusable, but not from an anatomical one. If we compare a moment the microscopical anatomy of the lung with that of the muscular tissue, we find a great similarity. We find in the lung all the restoring resources which we have in the muscles—connective-tissue, with meshes, nourishing and absorbing blood-vessels, nutritive and motory nerves; in short, all we find in a muscle except sensitive nerves; but this does not warrant an exclusion of restorative properties. A tissue cell of the lung is as capable of forming new cells as a muscle tissue cell. Nor does the present condition of science warrant the acceptance and maintenance of a specific blood diathesis in tuberculosis. Virchow, long since, has proven that the blood is utterly unable to hold or retain septic or putrid liquids. No author of former days, nor any of those upholding the germ theory of to-day, have ever been able to *prove* or show the least fact warranting the specific blood disorder, or specific germ in tuberculosis or other chronic affections of the lungs. The cheesy degeneration of the glands is a secondary affection; if blood-poisoning occurs in tuberculosis, so is it the *consequence*, and not the origin, of tubercles, which should be termed miliary abscesses. (See my classification of blood-poisoning, *Journal of the Gynecological Society of Boston*, December, 1869, page 356.) These facts are now corroborated by all modern pathologists. (See Waldenburg, *Die Tuberculose*, Berlin, 1869, page 465.)

The only reason for accepting the incurability can lie in the fact that thus far all therapeutical agents have failed. However, this is not astonishing, if we glance over the means that were employed? The mechanism of respiration has never been satisfactorily explained; the remedies recommended were either based on wrong conceptions, or they were very imperfectly applied. Our very best medical authors have tried again and again to succeed after failure upon failure, because they felt morally satisfied that such was possible. A man may fail with a correctly calculated agent if employed under wrong conditions; *i. e.*, we will suppose lime is necessary for calcification. We therefore prescribe correctly organic lime, but we forget to clear the lungs, and we fail of course. Or we clear the lungs and forget the lime—we fail again. Or we do both, but fail to balance equivalent absorption and excretion—we must fail again. And if we accomplish correctly all, and the nervous power is lost, we fail again in spite of correct CALCULATION OR APPLICATION, for we depend upon favorable CONDITIONS, without which all is useless.

Dr. Oakey, Jr., of Providence, R. I., a graduate of Harvard, has tried my method with so satisfactory results that he has disavowed homeopathy entirely, much to the disgust of the old gent, who is the most fashionable homeopathist in Providence.

## Progress of Medical Science.

**CONTRACTION OF THE PALMAR APONEUROSIS.**—At the meeting of the *Société Anatomique*, on March 9th, M. Richer read a paper on this subject, his remarks being based upon the appearances presented by the hands of an old man, whose body had been found in the dissecting-room. The lesion was symmetrical, and affected both hands almost equally. It was most marked in the fourth finger of the left hand. This finger was flexed into the palm of the hand, and could not be extended beyond a right angle with the metacarpus. A firm cord, analogous to the tendon of a contracted muscle, extended from the root of the finger to the base of the hand, and, on attempting to extend the finger, this cord became more tense. The two terminal phalanges of the finger had preserved their normal mobility. The little finger could not be entirely extended; at its base there was a small induration, from which extended a cord, which could be discovered only by the sense of touch, when the finger was forcibly extended. This cord joined obliquely the cord on the ring-finger. The medius also could not be extended completely, on account of the tension of the interdigital commissure. At its base, as well as at that of the index-finger, there was some induration, and the skin was adherent to the palmar fascia.

On dissection, the skin was found to be normal. The subcutaneous fat had disappeared in the neighborhood of the cords and indurations just described. The palmar aponeurosis opposite the ring-finger presented a very hard, rough, fusiform swelling, from which a ligamentous cord extended to the base of the finger. The fibres of this cord were inserted partly into the skin on the palmar surface of the first phalanx, partly into the sides of the phalanx, where they seemed to be mingled with the tendons of the interossei and the extensors. Opposite the other fingers the aponeurosis was thickened at the spots which were adherent to the skin. The interdigital fibres of Gerdy, which subtend the commissures of the fingers, appeared to be more numerous and tense than normal, between the little, ring, and middle fingers. Below the aponeurosis all the tissues were healthy. The articulations were normal, except for some erosions of the cartilaginous surfaces, and the tendons played freely in their sheaths.

The right hand was affected in an entirely similar manner, but in a slightly less degree than the left. Both elbows presented the lesions of an arthritis sicca—osteophytes in the lateral ligaments, and erosions of the cartilages. Microscopical examination of the retracted and thickened portions of the aponeurosis showed everywhere bands of tendinous tissue, which were simply more numerous and more densely crowded together in the retracted cord. The elastic fibres also seemed to be more numerous and larger. The skin was perfectly normal. Hence there were no traces of inflammation in the retracted parts.

A short discussion followed the reading of the paper, in the course of which M. Després maintained, in opposition to M. Richer, that the retraction was due to subcutaneous cicatrices, or to a traumatic inflammation of the aponeurosis. He called attention, in support of this view, to the frequency with which the affection is met with in joiners. M. Charcot, without absolutely contesting M. Després' statement, maintained that the retraction of the palmar aponeurosis is most frequently spontaneous. He pointed to the facts that it is from the beginning bilateral and symmetrical, and that all operations performed for its

relief have proved useless. It sometimes occurs in persons who have never used their hands for manual work.—*Le Progrès Médical*, May 12th.

**TREPANNING FOR FRACTURE OF THE SKULL.**—As a contribution to the literature of the operation of trepanning, Prof. von Linhart, of Würzburg, reports the case of a young soldier, who was admitted into the Julius Hospital in 1866, suffering from a lacerated wound of the scalp and fracture of the parietal bone and of the squamous portion of the temporal bone. As the bone was not depressed and the symptoms were slight, the wound was merely dressed and the patient put to bed. On the second day twitchings in the muscles of the face and limbs were observed, which gradually became more severe, and on the third day well-marked epileptic attacks set in. These attacks lasted 10 or 15 minutes, and recurred almost every 10 minutes. On the next morning the Professor trepanned the patient as an exploratory measure, and found a small, pointed splinter from the vitreous table firmly imbedded in the dura mater. This was seized with forceps and removed with some little difficulty. As there was but little depression of the fractured bone, no attempt was made to elevate it. The patient recovered quickly from the coma, and had no more epileptic attacks. Fourteen days after the operation he was able to be moved to his home.

In spite of this and some other successful cases, Prof. Von Linhart does not believe trepanning, either primary or secondary, to be of such great value as is claimed by many writers. His opinion is based on the facts that he has seen many desperate cases recover without the operation, and on the other hand has been convinced by many operations and post-mortems that trepanning alone will neither prevent nor cure a traumatic meningitis or encephalitis.—*Centralblatt für Chirurgie*, May 19th.

**ACUTE YELLOW ATROPHY OF THE LIVER.**—Dr. Daly has contributed the report of a case of acute yellow atrophy of the liver, which is specially interesting in connection with the theory that one function of the liver is to destroy poisonous matters in the system. He was called to see a married woman of thirty-eight, who had six children, the youngest of which she was then nursing. Suffering from jaundice, she had been for some days under medical treatment. The tongue was coated, pulse 90, and temperature 99.2° F. There was loss of appetite; the bowels were constipated; the stools pale, but not white; the urine full of bile; the skin and conjunctivæ slightly yellow. No pain was felt anywhere. The case was held to be one of catarrhal jaundice, and was so treated for four days, when suddenly delirium set in, with muscular twitchings; urine and feces were passed involuntarily; the pulse was 140, and the temperature 104.6° F.; the gums were covered with sordes, and the breath had an abominable odor. Acute yellow atrophy was suspected, but as yet there had been no decrease in the liver dulness. The following morning (the fifth day of attendance) the area of dulness had decreased remarkably, and in the evening the percussion sound was perfectly clear over the entire hepatic region. The patient died during the night. The cause of the disease was ascribed by the family to drinking impure cistern water, an opinion in which the physician and Dr. Murchison agreed. Several others of the family were also sick about the same time, and one of the children, a girl of seven, had jaundice, but she recovered after brisk purging. Possibly she escaped acute yellow atrophy because, according to Niemeyer, children do not have it.—*The Lancet*, May 19, 1877.

# THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

## ABUSES OF MEDICAL CHARITY.

THERE is a movement on foot in the city to organize a society for the control and suppression of the existing abuse of medical charity. No more opportune time than the present could have been selected for the scheme. Never before in the history of medical practice has the question assumed such an importance, as bearing upon the actual livelihood of a large class of struggling physicians. It is an acknowledged fact that professional incomes have decreased within the past two years. Under the circumstances this could hardly be prevented. Aside from the healthfulness of the season, the physician does not have so much to do as formerly, because even those of his patients who are sick have fallen into the habit of economizing on his services. In many of the cases in which he might have been called, he is not sent for at all, and a surreptitious dose of castor-oil, and a few mustard plasters, or catnip tea, or a gin toddy, does the business. And some of the best-paying patients are not ashamed to say that it is too expensive to be sick, and that the necessity of sending for the doctor is a positive pecuniary calamity. The physician is, in fact, looked upon more as a necessity in extreme cases than as a luxury in trivial ones. Many of the leading practitioners have had their incomes reduced one-third, while others have suffered a reduction of almost one-half by such an understanding on the part of their patrons. It is not because there are not as many sick as usual, but that, for pecuniary considerations, these patients are willing to run some risks rather than incur frequent professional visits. But, as we have before intimated, this is the result of a natural stringency in money matters, and cannot possibly be prevented. The association of the shrinkage of incomes with the abuses of charity is, however, of more importance, because it involves the possibility of a remedy. The managers of the charities are more to blame for this condition of things than those who

take advantage of them. There is at present more than the ordinary temptation to save expenses in everything. It can hardly be done in food and raiment, for neither the butcher, the baker, nor the tailor believe in giving to the poor for charity's sake. But the doors of the dispensaries stand open to receive every one who may choose to enter and obtain the benefits of gratuitous treatment. The number of applicants to these charities are increasing every year, and the profession is getting poorer and poorer. In olden times no one expected dispensary or hospital treatment, who could afford to pay even a small fee. Now the excuse of hard times is unblushingly offered by thousands, who cheat the practitioner, not only out of small, but not infrequently out of large fees. It is an old story to tell of hundreds of men and women who have incomes which would make the poor doctor absolutely independent, and yet who have recourse to the dispensary for free medical treatment. It is preposterous to assume that this abuse cannot be corrected by even ordinary care on the part of those who have such matters in charge. That it has not been done long ago is, perhaps, as much the fault of the medical gentlemen attending these institutions as any one else. The managers of these charities have no reason to complain of the number of persons treated, so long as professional services are so freely thrown away for the sake of clinical advantages. And this is a difficulty which is almost insurmountable in the way of necessary reform. In fact, we believe, if some of our dispensary and hospital attendants were compelled to restrict their services only to worthy applicants, they would rebel at once against what they would perhaps call a conspiracy against their legitimate clinical opportunities. In more than one dispensary in this city there are specialists, who quiet their consciences by never asking their dispensary patients whether they are able to pay a physician or not. Although this is downright professional swindling, and is placing a premium upon the fraudulent cupidity of a large and constantly increasing community, it is quietly winked at even by college professors, and is regarded as one of the necessities of advancing medical civilization.

But the real sufferer from all this manœuvring is the practitioner who is content with moderate fees, for whom bread and butter in hand is a positive necessity, and who cannot afford to trust to the chances of making a distinguished reputation in the future. This class is a very large one, is composed of hard and conscientious workers, and deserves some consideration from their more prosperous brethren. We are a little doubtful that they will obtain much of a show, considering the avowed and greedy selfishness of those who hold hospital and other similar professional appointments for individual advancement. If the new association to which we refer can succeed in arousing a sentiment of fair play on the part of some of the clinical monopolists, it will not have been organized in vain.

The crying necessity is for a radical change in hospital and dispensary management. In meeting such a requirement there is not the slightest danger that the poor will suffer. Even if all the dispensaries were abolished and the doors of all the hospitals closed, the needy would still have the requisite attendance. There is not a young practitioner in this or any other large city who would not be willing to attend the poor gratis in his own office, or visit them at their homes, provided he could be guaranteed against being cheated out of those fees which are lost in the mistaken and false charity of dispensary and hospital practice. But nothing can be done to effect any change in the present state of affairs, unless some parties really interested take hold of the question with a distinctly avowed purpose. The agitation of the question of the Medical Provident system had a tendency in this direction, but it has evidently amounted to nothing. This result has obtained because such a scheme as might be devised in connection with the provident plan might not work advantageously, but because the matter is unfortunately in the hands of those who are more or less indifferent to the pressing claims of the despairing professional bread-winner.

The best hope of reform rests in the efforts of men who shall be willing to work to correct the abuses; to go out of their way to detect frauds and to bring the same to the notice of the board of managers, and of the medical staffs of the different infirmaries. It is to the interest of the men who are really suffering as the result of the different abuses to follow up unworthy cases, even to the doors of the dispensaries, and into the wards of the hospitals, and enter a protest against their being treated as deserving objects of charity. By well-organized and permanent efforts in this direction, a sufficiently strong professional and public sentiment may be created to make it hazardous for any medical or other officer of a hospital or dispensary to knowingly admit to the benefits of the charity any patient against whom suspicions of pecuniary competency can be entertained. If the association which is being formed in this city is to be composed of this sort of working material, it can from the start be assured of the active and willing support of the rank and file of the profession.

**MALE WET-NURSES.**—The *Journal des Sages Femmes* has a notice of a German physician in Pomerania who makes a specialty of supplying wet-nurses. He excites the secretion of milk, not only independently of pregnancy, but in men as well as women. An applicant for a wet nurse is always asked whether a *male* or a *female* is desired. The former is preferred by some families, under the belief that greater vigor is thus imparted to the infants.

**HUMAN MILK FOR SALE.**—Chinese women sell their milk for about fifty cents per pint. The milking is performed in public to insure purity. It is highly esteemed as a nourishing food for old people and consumptives.

## Reports of Societies.

### AMERICAN NEUROLOGICAL ASSOCIATION.

*Third Annual Session.*

WEDNESDAY, JUNE 6TH.—AFTERNOON MEETING.

THE American Neurological Association convened at the College of Physicians and Surgeons, in New York city, June 6, 1877, and was called to order at 2.30 p.m., by the President, Dr. J. S. Jewell, of Chicago.

As the minutes of the preceding session had been printed and distributed among the members of the Association, on motion, their reading was dispensed with.

#### ANNUAL REPORTS.

DR. E. C. SEGUIN, of New York, Secretary of the Council, made the Annual Report, which was adopted.

DR. J. J. MASON, of New York, Corresponding Secretary of the Association, made his report, which was accepted.

DR. E. C. SEGUIN, Recording Secretary and Treasurer of the Association, made his report, which was accepted.

At the recommendation of the Council, the resignations of Dr. J. W. S. Arnold, of New York, and Dr. F. D. Lente, of Florida, were accepted.

It was voted that the Recording Secretary present Dr. William Detmold the thanks of the Association for the use of the room.

Dr. William A. Hammond and Dr. N. B. Emerson submitted new by-laws.

#### THE COMMITTEE ON NOMINATIONS,

as appointed by President Jewell, was as follows: Drs. Miles, of Baltimore; Shaw, of Brooklyn; Kinnicutt, Cross, and Emerson, of New York.

The business of the first meeting having been completed, the

#### INAUGURAL ADDRESS

of the session was delivered by the President DR. J. S. JEWELL.

The following is an abstract of the address:

"GENTLEMEN OF THE AMERICAN NEUROLOGICAL ASSOCIATION:—At this our third annual meeting, it has seemed to me appropriate that I should deliver at its opening a short address, as a means of enabling me to discuss certain matters which can hardly find suitable expression at any other time, or in any other way. The nervous system in its totality, which is professedly the object of our consideration, has striking peculiarities as a field for scientific and practical study. From whatever standpoint it may be considered, more unexplored territory lies within the confines of the spinal cord, medulla, and brain than in any other part of the organism. There is not a part of the body, it is probable, into which it does not penetrate, and hence, with which it does not establish relations. This is, on the one hand, for the purpose, so to speak, of being all ways informed as to the varying conditions of all parts of the organism, and on the other hand, for the purpose of exerting an influence upon the same. While it is, in the strictest sense, a special field, it is so happily situated as to give those who enter and cultivate it in a rational spirit no excuse for that narrowness of thought and sympathy so often and so unhappily found among those who cultivate specialties.

"Such, in brief, is the field of our study. In its culti-

vation for the future there are several things I should be glad to see realized.

"The first is, that in this country, henceforth, more attention and encouragement may be given to a thoughtful study of the healthy anatomy and physiology of the nervous system. No doubt there are many now among us who are endeavoring to keep pace with the progress in these fundamental departments of neurological science, and some few endeavoring to confirm or enlarge the boundaries of actually existing knowledge; but it cannot be denied that thus far very little, comparatively, has been done and made public, in our own country, towards advancing a knowledge of the normal anatomy and physiology of the nervous system. The reasons for its neglect thus far, whether good or bad, have now in a great measure passed away. The time has now come—and with it the opportunities—when we should undertake to make some solid contribution in this department of our work. To excite and encourage, and beyond this to prosecute such researches, should be one chief object of the existence of such a society as ours.

"Then again we need not less experiment, but more care as to the method and results. There can be no question in my mind that there is, relatively speaking, too little close, accurate thought, as compared with the mere observation of facts. The mere discovery of a new fact by sense of observation does not insure that the discoverer will ascertain its significance. What I mean to declare is, that mere sense observation has outstripped, and does this very hour outstrip, critical, careful thought. What we need is, not mere observers nor mere thinkers, but more men, who, like Bacon, Harvey, Bichat, and others, can not only observe, but, like them, think. I would be glad to see this Society in its work avoid with a set purpose this unfortunate course.

"With due respect to those who have labored in less favored times, I wish to see less reliance placed on the records of pathological cases, as they exist in the literature of the past. With a better knowledge of the anatomy and physiology of the body, with a broader range and basis of established facts than ever before, and with greatly improved methods for research, we are able happily to lay a surer foundation, let us hope, for trustworthy deductions.

"I want now to lay before you a few practical suggestions in regard to the organization and working of the Society.

"I am now, as I have been from the first, of the opinion that the Society is about as large as it ought to be until it has lived a little longer and done more good work. I do not say no new members should be admitted, but for a time let them be few, and admitted with caution. Then, again, the Society should continue to hold its next few meetings in the East. The bulk of its members must for a long time be here, and also the means for rendering them attractive. It should meet either in this city, Boston, or Philadelphia, or, what may be thought better, in some adjacent place of resort. Then again, the time of meeting of the Society should be so changed as not to conflict with other important meetings, which many of our members might feel like attending. I would suggest that the meeting be postponed till the second or last week in June, or until September. In regard to the publication of our papers and discussions: The only things to be done are either to publish an inexpensive account of the proceedings and abstracts of discussions and papers, or to publish a volume of transactions. Of these two plans the latter is every way preferable. A subscription of from fifty to one hundred dollars from each member would completely insure the ap-

pearance of the volume. To render the work of the Society more effectual, I would recommend a diminution in the number of officers, who should, as now, be aided by a council in discussing purely business questions, which should rarely, if ever, occupy the attention of the Society as a whole; and that the Secretary be charged with the not very onerous duty of editing the materials, employing such aid as he may need. I would also suggest the propriety of the appointment of committees to report at subsequent meetings on definite subjects.

"Such are a few of the suggestions which occur to me, and are offered because of their importance. I had intended, at first, to have made a survey of the general field of neurology and to have indicated with some fulness and particularity the direction and tendency of research, and to have mentioned many of the yet open questions which appear to be within the field of neurological medicine; but it has seemed to me the suggestions which I have made would be of more importance to the Association.

"I will conclude, therefore, gentlemen, in the expression of something more than a hope,—that we may, at this meeting, make a new departure, and though our number is small, that we may remember that the utility and renown of this Society will not depend on its numbers, but on the character of its labors."

Next followed the exhibition of an interesting case, by DR. WILLIAM A. HAMMOND, of New York.

The patient, a boy of 18, the Doctor said, might be considered as a case of total moral depravity. He would lie and steal to any extent, without any reason: would steal clothes and other articles, sell them for a trifle, and then give the money away. The boy had been placed in several houses of correction, but they could do nothing with him. In reply to the question, "What makes you do these things?" he said, "I can't help it." He did not seem to be lacking in intelligence. His mother had for a long time noticed blood upon his pillow. Dr. Hammond considered the case one of epilepsy. Weight of child at birth, one pound. His father is an exceedingly neurotic individual.

#### LEAD POISONING IN FROGS.

DR. J. J. MASON, of New York, read a paper on this subject, which suggested a new field for experiment.

Notwithstanding the important services which experiments upon this animal have rendered in discovering the mode of action of other toxic substances, not even an allusion to the action of lead upon the system of the frog, can be found in toxicological literature.

The subject was divided into two portions:

1. Acute poisoning; 2. Chronic poisoning.

In the former, the poison (acetate of lead) was introduced under the skin; in the latter, by placing the animals in a solution of the same salt.

The acute form of poisoning is characterized by paralysis of the heart with preserved integrity of the motor nerves and muscles; while, in the chronic form, paralysis of the muscles of volition, with their nerves, invariably results, leaving the heart intact.

The muscles always show Erb's *entartungs* reaction to electricity, a characteristic feature of lead palsy in man. A ready method is here found of inducing this condition of the muscles at will, and its value in the study of the pathogeny of lead paralysis is suggested to the consideration of the Association.

In view of the little we know on this subject and of the difficulty of obtaining autopsies in man and failures to induce the same condition in warm-blooded animals, may not much be added to our knowledge by further research on lead poisoning in the frog?

The paper being open for discussion,

DR. HAMMOND, of New York, inquired if there was any evidence of lead being in the nervous system.

DR. MASON could not say, as he had made no examination.

DR. JEWELL.—You found no change in the cord and applied no chemical tests?

DR. MASON.—No, sir, but I wish to do so.

DR. JEWELL remarked that formerly he had considered the trouble in lead poisoning to be central, and even now was inclined to that view, though he had the record of several cases which had raised a doubt in his own mind as to the truth of this.

DR. SEGUN stated that he once had the opportunity of making an observation bearing on this point. The patient was recovering from lead paralysis at the time he was carried off by a diarrhoea. Examination of the muscles showed the usual degenerative change. Sections through the cervical enlargement showed slight granular change in the ganglionic cells of the anterior horns. At that time (1875) Dr. Seguin took strong ground in favor of a central affection, and is still disposed to this view, though not as strongly as before.

DR. T. B. M. CROSS, of New York, did not favor local absorption, but considered the affected region central and high up.

There was some further discussion in regard to the different modes of communicating lead poison and of the occurrence of lead paralysis in printers. Several of the members of the Association expressed a hope that Dr. Mason would continue experimenting in the direction he had begun.

THE PRESIDENT, DR. J. S. JEWELL, then made a verbal report to the Association on the progress he had made in the examination into the

STRUCTURE AND FUNCTIONS OF THE GANGLIA ON THE POSTERIOR ROOTS OF THE SPINAL, AND ALSO OF THE CORRESPONDING PART OF THE CRANIAL NERVES.

DR. JEWELL'S remarks were a continuation of a paper upon the same subject, read before the Association at the last annual session.

He stated that his researches were far from being complete, but to him were suggestive. An important question was as to what became of the fibres which appear to rise from the nerve-cells found in the ganglia in question. Do they pass toward the cord or toward the periphery of the body? The Doctor's first opinion was the same as that held by many others since the time of the early observations of Kölliker—that they pass toward the periphery—but he has since abandoned that opinion. His opinion now is, that they do not pass either way, but that they join the axis-cylinders of the fibres of the sensory root, at the so-called "constriction of Ranvier," as these fibres pass through the ganglion. This view he was first led to entertain by seeing preparations of these ganglia made by Dr. Amidon, of New York, and after reading the account of these bodies, given by M. Ranvier, who describes what he calls the "*terminaison en T.*" This mode of termination of nerve-fibres in other nerve-fibres, Dr. Jewell has since ascertained, had been described by R. Wagner, of Göttingen.

DR. JEWELL has abandoned his opinion that the nerve-cells of the ganglia give off two processes, which connect with either two nerve-fibres, or one other cell and a fibre, or with two cells. He now believes that they are never connected but with one fibre, and that fibre connects, as already described, with the axis-cylinder of a sensory nerve-fibre, as it passes through the ganglion. But for what purpose does this connection ex-

ist? This question, Dr. Jewell thinks, is fully answered by making sections, in the living animal, of the posterior or sensory root, at one time between the cord and ganglion, and at another on the peripheral side of the ganglion. In either case Wallerian degeneration sets in, but in a curious manner. In the case of section on the central side of the ganglia, the degeneration is toward the cord, not toward the ganglion, while in the case of the section on the peripheral side of the ganglion, the degeneration of the nerve-fibres takes place toward the periphery, and not toward the ganglia. These observations show conclusively that the ganglia exert a conservative influence over the fibres of the sensory nerves throughout their whole length, from the periphery to their implantation in the spinal cord. Here, then, we have a highly probable determination as to the function of the nerve-cells in the ganglia on the superior roots of the spinal nerves. They exert an influence on the nutrition of the fibres of the sensory root. Their function is trophic. They are part of a *trophic nervous system*.

Another question arose as to whether these same ganglionic bodies do not exert an influence on the non-nervous tissues of the body, through the sensory nerves with which the spinal ganglia, on the one hand, and the ultimate anatomical elements of the tissues, on the other, stand in such intimate relations. Dr. Jewell announced that it was his conviction that such is the case. The nutrition of most parts of the body is, to a certain extent, and in a certain manner, under the control of the mechanisms found in the ganglia. Dr. Jewell did not want it understood that it was his opinion that the nutrition of the body *depends* on either the spinal ganglia or any other part of the nervous system, but that it is to a certain extent under its control. Disease of the ganglia, and also of the spinal cord, may lead to such changes in nutrition as to lead to the so-called idiopathic inflammations we so often witness in the skin and other parts of the body, and indeed any cases involving nutritive change, side by side with changes in blood-supply, which cannot be fairly connected with a local injury, mechanical, chemical, or otherwise. As regards the vascular changes which follow in the wake of irritative tissue-change of presumed neurotic origin, they are to be explained on quite different grounds, since they occur through the agency of a different class of nervous mechanisms. It was Dr. Jewell's opinion that the spinal cord contains in connection with the medulla, and possibly the brain, a central mechanism, which may be properly called trophic, and that the spinal ganglia probably bear the same relation to it that the ganglia on the fundamental chain of the sympathetic, so called, do to the central vaso-motor mechanisms of the cord and medulla. Dr. Jewell stated that it would not be possible for him at present to go at length into the reasons for his beliefs, though he would certainly do so before long. He had simply desired to report progress.

DR. JEWELL having expressed a desire to have the subject of his paper discussed,

DR. HAMILTON asked for an explanation of the way in which atrophy occurred, as, for instance, in progressive facial atrophy.

DR. JEWELL replied, using the blackboard to illustrate his remarks, that from a certain nerve-cell, in which we suppose a nerve-fibre to terminate, there are given off two or three filaments: one of these passes to another group of cells, a second to another group of cells, and so on. One of these groups has a trophic function, another group has a sensory function, and another group has some other function. Now,

it is possible to have this trophic group the seat of disease, which shall be exerted through its cells all along the fibre, while its sensory function remains intact. His belief was that the sensory nerve-fibre conducts all kinds of sensibility. Only in the above way could he explain local inflammation or local atrophy.

The paper was further discussed by Drs. Seguin, Hammond, Cross, Miles, and Mason.

#### FIRST DAY.—EVENING SESSION.

The Association was called to order by President JEWELL, at 8 P.M.

The first paper was by DR. H. D. SCHMIDT, of New Orleans, who was unable to meet the Association in person during the present session. The paper was read by the Secretary, Dr. Seguin. The communication was accompanied by a number of thin microscopic sections, of different ganglia of the sympathetic nervous system, and also some sketches of ganglionic bodies.

The object of Dr. Schmidt's communication was not only to offer an opportunity to those persons willing to devote the necessary time to the examination of the specimens, of convincing themselves of the truth of his former statements, but moreover to direct the particular attention of the Association to the structure of these bodies, each of which seems to represent a complete nervous apparatus in itself, and, also, to the importance attached to a true knowledge of the particular mode in which the sympathetic nervous system operates. As the investigation of the structure of these bodies is one of the most difficult in histology, the Doctor considered it necessary that the investigator, in order to recognize this structure, should be able to represent in his mind the exact form in which sections of a complicated body of a certain form, made in different directions, would appear to the eye. Dr. Schmidt called attention to the fact that in examining the ganglionic bodies, lodged between the double contour nerve-fibres of the *plexus gangliiformis* of the pneumogastric nerve, the meshes of the network forming the capsule would be found much coarser, a fact which rendered these bodies very suitable for research. Attention was called to the fact that from each sympathetic ganglionic body, two different kinds of processes arise: the larger of these, having the appearance of true axis-cylinders, are most probably transformed into double contour nerve-fibres, while the finer and shorter ones contribute to the formation of the nervous network of the capsule, from which the fine fibrillæ, forming eventually the sympathetic nerve-fibres, arise. Thus we have two different kinds of nerve-fibres arising from one and the same ganglionic body. Now the question arises, does this arrangement bear any relation to the rhythmical or peristaltic action of the involuntary muscles? And further, is one kind of nerve-fibre motor while the other is inhibitory? If so, which are the sensory fibres? Another question to be answered is, whether those sympathetic ganglionic bodies, with the nerve-fibre arising from them, lodged in the plexus gangliiformis of the pneumogastric nerve, bear any relation to the inhibitory action of this nerve? Dr. Schmidt's view is that difference in structure conditions a difference in function.

The paper was discussed by Drs. Jewell, Seguin, Mason, and Miles; after which

Dr. Mason gave an informal demonstration of the structure of the spinal cord of the American bull-frog, and the medulla oblongata and spinal cord of the alligator, by means of fresh and permanent microscopic specimens. Several microscopes were provided for the purpose.

Dr. SEGUN showed a number of transverse sections of the spinal cord of the green sea-turtle, exhibiting remarkably long cell-processes proceeding from the anterior horns into the white columns. There were also shown three photographs of the same specimens, made by Dr. J. W. S. Arnold.

At 9:20 P.M. the Association adjourned to attend a reception at the residence of Dr. William A. Hammond, to which he had invited the Association and a number of the profession in New York.

#### THURSDAY, JUNE 7TH.—AFTERNOON MEETING.

The Association was called to order at two o'clock by President JEWELL.

The Secretary read the report from the Council recommending the following gentlemen for election as active members. Dr. V. P. Gibney, and Dr. E. C. Spitzka, both of New York. These gentlemen were unanimously elected.

The first paper was read by Dr. N. B. Emerson, of New York, and entitled

#### SYPHILITIC SCIATICA.

Dr. EMERSON called attention to the fact that syphilis is very infrequently recognized as a cause of sciatica. Out of the reports of sixty-three medical men, in answer to Lauder Brunton's questions in regard to sciatica, only twelve spoke of the syphilitic form.

There was sufficient clinical and post-mortem evidence for making the statement that syphilitic neoplasms are capable of producing violent pains and loss of motor function in the sciatic nerve by pressure. Cases were given to substantiate this point. The Doctor considered it established that the syphilitic diathesis is capable of producing neuralgia in the sciatic nerve in some occult manner, without lesion. His reasons are, in brief, as follows:

1. Cachexia is acknowledged to be a frequent cause of neuralgia.
2. Syphilis is a notable cause of cachexia.
3. Syphilitic cachexia and neuralgia are frequently found to coexist, and with relief of cachexia comes relief of neuralgia.

For a diagnosis of syphilitic sciatica, the patient must have been free from sciatica previous to the syphilitic attack: an attack in the late stage of syphilis is more significant than in the early. The prognosis of syphilitic sciatica is the same as that of the syphilis which causes it. The treatment is practically that of syphilis; opiates may be necessary for the relief of pain; ferruginous tonic remedies should be made use of for the relief of the cachexia.

The next paper was read by Dr. EUGENE DUPUY, of New York, on

#### HEREDITARY EPILEPSY.

It is well known that Dr. Brown-Séquard has discovered that certain lesions of the spinal cord, or the brain, or the sciatic nerve, in Guinea-pigs, will give rise to an epileptic malady in these animals. In from three to six weeks after the operation, it is found that an alteration in the nutrition takes place in an area of skin, which is limited by a line starting from the outer canthus of the eye, and running to the median line on the upper lip enclosing the nostril, thence backward, enclosing the lower jaw to the anterior portion of the shoulder to the median dorsal line, to the base of the ear and inner canthus of the eye. The alteration in nutrition takes place on the side corresponding to the injury. It consists in this, that the faculty of feeling pain, heat and cold, disappear by degrees, while tactile sensation appears to be exalted. In a few days it is found that tickling this zone of skin will give

rise to twitchings which are limited to the muscles of the eye and the eyelids on the same side. Later, the muscles of the mouth and of the face participate; still later the contractions become more general, until this whole side becomes the seat of convulsions; then the convulsions attack the other side also.

When things have come to this point the convulsions precede, by a very short time, a complete loss of consciousness. If the subject of experiment be a white Guinea-pig, it is found that there is paleness of the face, but in all cases there is a little foam at the mouth and dilatation of the pupils. In some cases the animal utters a cry, probably corresponding to the epileptic cry in the human species. Not only are the convulsions identical with those in epileptic man, but there is also loss of consciousness, a state of torpor, stupidity, and even in some cases something like insanity.

It happens that such animals recover spontaneously, and in so doing, all of the phenomena described above occur in a reverse order, and the zone of skin regains its lost functions. When the epilepsy is due to the destruction of the sciatic nerve, the foot of that side loses the two outer toes, so that the animal has only one toe, the inner. When young are born to such a parent or parents (for it matters not whether one or both of the parents have been operated upon) they have this peculiarity of having only one toe on the posterior foot. Sometimes, however, they have additional toes, which in this case are attached by a pedicle to the limb.

Now all of those peculiarities which have been observed in the parents, all things in all their details, are witnessed also in the Guinea-pigs, hereditarily born toeless, who have developed epileptic phenomena. There is, therefore, an inheritance of a power to develop the disease, but no inheritance of the disease itself. Dr. Dupuy has examined the sciatic nerve of such animals and found them healthy, before, during, and after the existence of the disease. He has also followed these experiments through five generations.

Dr. Dupuy made allusion to the doctrine of Balbiani on embryogeny, and thought that, according to Balbiani's laws, the phenomena of inheritance, in the case of epilepsy, could be explained, epilepsy being a malady of nutrition like all other nervous diseases. Dr. Dupuy stated that only those young which are born with alteration in the normal nutrition of parts become epileptic; in such the disease fatally occurs.

The paper being open for discussion,

DR. JEWELL inquired whether the animals operated upon invariably transmitted their deformities.

DR. DUPUY.—No, not invariably, but it is so sometimes.

DR. HAMMOND remarked that he had been astonished at the small proportion of transmitted cases of epilepsy in the human species.

DR. LORING inquired if, in following out five generations, those two toes were absent, or whether the tendency was towards the normal. He made allusion to the non-transmission of the deformity of the feet, in the case of the Chinese women, and to the inheritance of diseases of the eye.

DR. DUPUY stated that the tendency was, of course, towards the normal number of toes, since so small a number of the young have the deformity; that it appears, to have a lesion transmitted, it must cause an alteration in nutrition. He made reference to a paper which he had published, in which he had shown that the phenomena following a lesion of the sympathetic nerve, or corpora restiformia, in the Guinea-pig, are invariably inherited by their young, and it is known that these lesions modify the organs of sight. In re-

gard to the Chinese, he did not think there was much reliable information.

DR. SEGUIN remarked that the power to resist these hereditary influences was greater in the human subject than in the lower animals.

DR. JEWELL said that there was no deformity transmitted except where some of the parts have been removed; that a distinction should be made between those changes which are morphological and those which are structural.

DR. SPITZKA stated that he had read in Obersteiner's Essay, that those animals which are most likely to become epileptic are those which resemble their parents in color of hair; that the experiments of Westphal led to the view that epilepsy depended upon hemorrhage in the medulla oblongata. Dr. Spitzka said he did not admit that the cell of Balbiani was considered as more important than the cell of Purkinje.

DR. DUPUY remarked that all biologists accepted the views of Balbiani, and moreover that it is taught that Balbiani's cell and Purkinje's cell are two different things. The first carries ancestral, and the second maternal tendencies.

The paper was still further discussed by the above gentlemen and Dr. Mason.

#### LOCOMOTOR ATAXIA.

DR. J. C. SHAW, of Brooklyn, exhibited a very interesting case of locomotor ataxia in a female child four years of age. When eighteen months old she had measles and scarlatina, and in a few months afterward she began to experience difficulty in walking, followed by an inability to hold things in her hands. This difficulty increased until she was unable to walk. She now presents marked ataxic movements in both of the upper and lower extremities. When the child was supported, and she attempted to walk, both of the lower extremities were jerked forward and outward and the heel brought down first, in a truly ataxic manner. There did not appear to be any anaesthesia. It had been observed that at times the child would scream out without apparent cause. On May 2, 1877, she screamed out suddenly and said that she had a pain in her left heel. She has no muscular atrophy or paralysis, and the muscles react normally to Faradization.

Dr. Shaw stated that the diagnosis was made by exclusion, and gave his reasons for excluding, brain tumor, lesion of the ganglionic cells of the anterior horns, paralysis from peripheral irritation, and pseudo-hypertrophic paralysis; and advanced an argument to show that it was a case of sclerosis of the spinal cord—disseminated, perhaps, and located in the lumbar part of the cord, and in the posterior columns.

The paper was discussed by Drs. Seguin, Hammond, Shaw, and Loring.

The next was a paper read by DR. WILLIAM A. HAMMOND, of New York, which was, as Dr. Jewell afterwards remarked, interesting from a scientific as well as a theological point of view. The title of the paper was,

#### THE ODOR OF THE HUMAN BODY AS DEVELOPED BY CERTAIN AFFECTIONS OF THE NERVOUS SYSTEM.

Dr. Hammond called attention to some facts in regard to the natural odor of the body in the human species, and of the faculty which some of the lower animals possessed,—that of differentiating between the odors of different individuals. Besides the inherent odor of the body, there was reason for believing that an entirely different one may be given off, not only as a consequence of disease, but as a result of emo-

tional disturbance. During the middle ages, manifestations of the kind in question were not uncommon in the persons of both sexes, and were attributed to miraculous power. That such cases existed was probable, not, however, as a special gift of God, but as a neurosis similar to other instances which had come under the Doctor's own observation. Cases were then cited, of a number of the more important instances among the saints, who were considered highly odoriferous. So far as the author of the paper was aware, there had been no attention given to the subject in the relations now under notice. The cases cited by Dr. Hammond as bearing upon this point were briefly as follows:

A young married lady of strong hysterical tendencies, from whom, during a paroxysm, an agreeable odor, similar to that of violets, was exhaled only from the left lateral half of the anterior wall of the chest. At such times the perspiration was remarkably increased in this region, as compared with the corresponding part opposite. The odor was perceptible at a distance of several feet, but was entirely absent during the intervals of the paroxysms. From an examination of an alcoholic extract of the odoriferous perspiration exhaled by this patient, it was presumed that the odor was due to the presence of butyric ether. The local application of several remedies to the parts, among which were preparations of carbolic acid, soap and water and other alkaline substances, gave the patient only temporary relief from the odor; but the internal administration of the salicylate of soda, in doses of five grains, entirely cured this lady of her violaceous odor, and the perspiration of the region was reduced to the normal character.

A second case was that of a young lady in whom the first exhibition of the odor (in this case that of pine-apple) occurred contemporaneously with an attack of chorea.

In a third case a pine-apple odor was emitted from the skin of the head, neck, and chest of a woman whenever she was angry.

A fourth case was that of a man who, during frequent hypochondriacal periods, emitted a violaceous odor. Occasionally cases were met with from whom a disagreeable odor was exhaled during sexual excitement. No opinion as to the actual and immediate cause of these odorous emanations was expressed, further than that they were due to a nervous disturbance.

Dr. Hammond passed around a small vial containing an alcoholic extract of the odoriferous perspiration of his first patient, which had a distinct violet smell; also a second vial of the same extract, with the addition of bicarbonate of soda, smelling strongly of pine-apple.

The paper was discussed by Drs. Jewell, Beard, Hammond, Seguin, Hamilton, and Spitzka, cases of a similar nature to those mentioned in Dr. Hammond's paper being cited.

After the close of the discussion Dr. GEORGE M. BEARD, of New York, proceeded to read a paper on

#### THE ENDEMIC TETANUS OF EASTERN LONG ISLAND.

That tetanus had been more frequent in portions of Suffolk County, Long Island, than in other parts of the country was well known. Dr. Beard had passed several of his summers there, had conversed with a number of the physicians and residents, and corresponded with nearly all of the physicians of the county, asking for facts and not opinions.

Dr. Beard's conclusions up to statement are as follows:

1. For the last three-quarters of a century there has

been an endemic tetanus in certain portions of Suffolk County. It consists of both the traumatic and spontaneous varieties, and affects animals as well as man.

2. This endemic abounds mostly in the towns of the south side, especially at the Hamptons, is less common in the central towns and on the north side, and in Montauk does not exist.

3. The endemic has been on the decline for the past ten or fifteen years, and in the central portion (excepting Riverhead) no longer exists.

For the causation there are three conceivable theories,—geology, the use of fish on the land as manure, and dampness in the air.

The theory based upon geology and advocated by Dr. B. D. Carpenter, who has studied the subject, appears to be disproved by the decline in recent years. Geology is a constant factor. In favor of the fish-on-the-land theory is the occurrence of the disease in those localities where fish are most used and the decline of the disease with the decline in the use of fresh fish as manure. Dr. Beard thinks, however, that the facts up to date seem to favor the theory of dampness in the air combined with the local dampness of the soil.

Dr. Beard would treat a case of tetanus by calabar bean (English preparation), in small doses every hour or half-hour, so as to affect the pupil, and at the same time apply ice-bags to the spine. As suggested by Dr. Carpenter, the patient should be kept absolutely quiet, if possible. The local application of the oil of turpentine to all wounds is practised by a number of the physicians of Suffolk County, and is to be recommended. The apprehension felt by New York surgeons that tetanus is likely to follow surgical operations in Suffolk County is not justified by the facts as they now stand.

#### SECOND DAY.—EVENING MEETING.

The Association was called to order by the President at 8 P.M.

The first paper of the evening was read by Dr. A. D. ROCKWELL, which consisted of the history of a remarkable case of

#### INTERMITTENT HEMIPLEGIA.

A brief outline of the case is as follows: A stair-builder, aged forty-nine, in fair health, was seized one afternoon in July with dizziness, loss of speech, and complete paralysis of the left side, which lasted for twenty minutes, and then entirely disappeared. Similar attacks occurred every other day for three weeks thereafter, at about the same time of the day. One day, about the middle of August, he had a much severer attack at 11 A.M., which was repeated every day at the same hour until Sept. 3d, and between 11 A.M. and 4 P.M. each day; during all this time paroxysms recurred three or four times. In the more severe attacks he was unable to walk or speak, but during the milder ones he could move with difficulty and speak indistinctly. Dr. Rockwell's treatment consisted of a mild *séance* of general Faradization, in conjunction with three two-grain doses of quinine daily. There was decided improvement at once, and on the 25th of September he was discharged as apparently cured. He remained so until December 4th, at which time the paroxysms re-occurred and in a more violent form, and he died on the following day.

Post-mortem examination showed congestion of the surface of the brain; pia mater covered with a thin film of organized lymph from old inflammations; texture of the brain softer than normal; choroid plexus enlarged and cystic; basilar artery and part of the cir-

cle of Willis enlarged and atheromatous; mitral valves and liver in a condition of fatty degeneration; serous effusion at the base of the brain, but there were no arteries ruptured, no evidences of embolism or thrombosis.

As the above described pathological changes seemed hardly sufficient to account for the unusual symptoms and suddenness of death, Dr. Rockwell discussed at some length the probable cause of the final result, and, by means of exclusion, thought it probable that death was due to a spasm of the vessels in the brain tissue, which rendered it unfit to discharge its proper function.

In the course of the rather lengthy discussion which followed the reading of the above paper, Dr. Hammond cited a case in his own practice which he considered analogous with Dr. Rockwell's case.

Cases were also cited by Drs. Beard, Kimmicutt, and Jewell, and the subject further discussed by Drs. Emerson, Rockwell, Shaw, Spitzka, and Dupuy.

The next paper was read by DR. V. B. GIBNEY, of New York, and entitled

#### SPINAL IRRITATION IN CHILDREN.

The paper consisted of the clinical histories, together with remarks upon a number of cases which Dr. Gibney was wont to consider as cases of spinal irritation.

In the course of the lengthy and animated discussion which followed it was made evident that there was some difference of opinion as to what spinal irritation really was, several of the members of the Association having expressed their disagreement with Dr. Gibney on this point. The question of local malnutrition was raised and freely discussed.

At the close of the discussion DR. E. C. SEGUIN read a paper entitled

#### A CLINICAL CONTRIBUTION TO THE STUDY OF POST-HEMIPLEGIC CHOREA.

He related the history of two cases. In the first, observed in 1877, a young man of eighteen years suddenly became paralyzed in the left arm, without disorder of sensation. Later, some numbness appeared in the left hand, and in about two months convulsive movements manifested themselves in the left upper extremity. About this time the left leg became affected with weakness and tremor; later still, the lower part of the left side of face twitched. The arm and leg were the seat of convulsive movements of choreiform type, made worse by emotion or attempt to use parts; no ataxia; sensibility slightly lessened in hand. Later there occurred palsy of third cerebral nerve on the right side; palsy and spasm in left face. Patient died, but autopsy could not be obtained.

Case second was presented to the Association. Its history was briefly this: Male, aged twenty-six years; in April, 1876, sudden right hemiplegia, with partial loss of consciousness and temporary aphasia. During second and third months convulsive movements appeared in the right arm and hand, while great recovery of muscular power was obtained. Partial right temporal hemiopia. Numbness and slight anaesthesia in face, arm, and leg on right side. A few epileptiform attacks since. Seven years ago had chancres, followed by doubtful secondary symptoms. Movements on right side are now nearly normal in force; while at perfect rest slight oscillations (of paralysis agitans type) occur in fingers and hand. During attempt to use hand violent inco-ordinate movements occur, irregular extension and flexion, of quasi-choreic, quasi-ataxiform type. Partial right hemiopia and hemianaesthesia.

In both these cases the movements, first described

by Dr. S. Weir Mitchell, are present; and from the other symptoms present it would appear as if the lesion in these cases had been in the basal part of the hemisphere, just below and posterior to the thalamus opticus, involving, to a certain extent, the internal capsule. In the first case the lesion extended downward so as to involve the crus or the origin of the third nerve.

#### WEDNESDAY, JUNE 28th.—AFTERNOON MEETING.

The Association was called to order at 2 P.M.

The Committee on Nominations presented the following report, through DR. MILES, its chairman:

*For President*—Dr. J. S. Jewell, of Chicago.

*For Vice-Presidents*—Dr. F. T. Miles, of Baltimore, and Dr. S. W. Webber, of Boston.

*For Corresponding Secretary*—Dr. J. J. Mason, of New York.

*For Recording Secretary and Treasurer*—Dr. E. C. Seguin, of New York.

*For Curator*—Dr. T. A. McBride, of New York.

On motion, the report of the committee was accepted, and the gentlemen named duly elected officers of the Association for the ensuing year.

Under the head of Miscellaneous Business the President read a letter from Dr. William A. Hammond, offering to the American Neurological Association a prize of two hundred and fifty dollars to be awarded at its next annual session on the favorable report of a committee of three of its members, to the author of the best essay on the anatomical and physiological effects of strychnia on the brain, spinal cord, and the nerves.

#### COMMITTEE ON PRIZE ESSAY.

Dr. S. Weir Mitchell, of Philadelphia; Dr. J. S. Jewell, of Chicago; and Dr. E. C. Seguin, of New York.

The reading of papers being next in order, DR. J. C. SHAW read a short paper entitled,

#### A CONTRIBUTION TO THE SYMPTOMATOLOGY OF BRAIN TUMOR.

Given in brief the two cases cited were as follows:

A lady, aged fifty; "choked disk," both eyes; dizziness, headache, attack of falling, without convulsions general or local; no paralysis. Post-mortem examination revealed a sarcomatous tumor in the right temporal fossa, pressing upon the inferior and middle frontal convolutions.

W. P., aged twenty-nine; male; "choked disk;" attacks of falling without loss of consciousness; no paralysis, choked disk lasting three and a half years without passing to atrophy; vision  $\frac{20}{40}$ . Post-mortem—Pedunculated cystic tumor pressing on the anterior surface of the left temporo-sphenoidal lobe. This man was one of the victims of the fire in the Brooklyn Theatre.

The paper was discussed by Drs. Loring, Seguin, Miles, and Dupuy.

#### VASO-MOTOR CENTRES.

DR. EUGENE DUPUY made a communication to the Association on the above subject, which was to the effect that vaso-motor centres are not to be looked for in the spinal cord or brain, but outside of them. The vaso-motor centres are made up of the ganglionic system and of exceedingly numerous ganglionic cells, that are to be found scattered in the pia mater in the neighborhood of the medulla oblongata and the pons; also in the pia mater of the anterior parietal portion of the brain; also from ganglia that are found on the

track of the ganglia of the trigemini, and the ganglia of the spinal and cerebral nerves; also from the ganglia that are scattered through the cranial and other viscera.

That vaso-motor fibres only become connected with the cerebro-spinal system at their apparent origin, that is to say, at that point where the nerves get their sheath of pia mater after leaving their centres.

A warm and lengthy discussion followed the reading of this paper, in which Drs. Jewell, Seguin, and Dupuy were the chief participants.

#### LOCALIZED LESIONS OF THE BRAIN.

DR. E. C. SEGUIN read a report of seven cases in which more or less limited lesions of the cerebral cortex had been connected in life with definite symptoms.

The cases were grouped in three categories.

*First.*—Cases in which a limited lesion produced aphasia with or without hemiplegia. In Case I. ramollissement of the convolutions, in front of and just behind the fissure of Rolando on the left side, produced right hemiplegia and complete aphasia. Much recovery of motion occurred; aphasia remained complete. Careful examination of brain showed that the posterior part of the third frontal convolution and the folds of the island of Reil were involved in the lesion. In Case II. embolism of the first part of the left middle cerebral artery produced right hemiplegia with complete aphasia. There was ramollissement of the superficial part of the left third frontal convolutions and of the first two folds of the island of Reil and their subjacent white matter. In Case III. chronic aphasia of varying degrees, epileptic attacks, and partial temporary right hemiplegia were found to have been caused by a chronic pachymeningitis adherent to the altered left third frontal convolution near the fissure of Sylvius. Death in status epilepticus, with complete right hemiplegia, caused by extensive central softening of left hemisphere; very recent compared with meningitis. In Case IV. a secondary (by infection) tubercular meningitis, with its focus about the left middle cerebral artery and over the third frontal convolution and the folds of the island of Reil, produced intermittent aphasia (occurring almost every forty-eight hours), and at the close of life, in twelve days, there were complete aphasia and right hemiplegia.

*Second.*—Cases in which a limited lesion produced paralysis. Case V.: Small patch of softening in the middle of the left ascending frontal convolution, reaching inward to roof of ventricles, produced a right hemiplegia without aphasia, and probably without facial palsy. When examined, had palsy of right arm, none of face or tongue, and was paraplegic (from spinal lesion found in cervical region).

*Third.*—Cases in which a limited lesion gave rise to limited convulsions. Case VI.: A young man, injured on top of head, developed common epilepsy, replaced by local epileptiform spasms in left face, neck, hand, and arm; paresis of these parts. Later left hemiplegia and return of general spasms. Autopsy showed injured skull, thickened bone, adherent thickened bony dura over upper (inner) end of left ascending and first frontal convolutions, a sarcomatous tumor, starting from adherent dura and penetrating into nearly whole of upper half of right hemisphere. Case VII.: Septicæmia, suppurative meningitis, and two abscesses in cortex of brain. One as large as a large almond in lower part of left second frontal convolution, not involving more than anterior margin of the third, gave rise to no symptoms. The second, about the size of a pea, situated in the white matter

just under the cortex of the middle part of the right second parietal convolution, was in all probability the cause of very singular epileptiform (no loss of consciousness) spasm, which occurred early in the disease, in the left hand, arm, and face.

These cases seem to favor recent views on the localization of function in the cerebral cortex. The first group emphatically support Broca's hypothesis of a speech centre in the left third frontal convolution, and the anterior folds of the island of Reil. The cases of the third category also give support to Hitzig and Ferrier's views. The author is not prepared to accept so fine a localization as proposed by these gentlemen, but it seems to him that we are now in a position to speak of excitable and non-excitable regions in the cortex (pathologically speaking).

The discussion of this paper continued till time for adjournment, and yet the participants were not willing to quit a subject so fruitful of argumentative debate, so it was voted to resume the conflict at the evening meeting.

#### THIRD DAY.—EVENING MEETING.

The Association was called to order at 8 P.M. by President JEWELL.

On motion of DR. G. M. BEARD, it was resolved to hold the next annual session of the Association in the city of New York.

On motion of DR. T. M. B. CROSS, of New York, the Recording Secretary was directed to preserve fifty copies of the first volume of the Association's Transactions.

On motion of DR. E. C. SPITZKA, a vote of thanks was tendered to Mr. Josiah Roberts, of the New York Medical Record, for his attendance and note-taking during the entire session, thus securing a full report of the proceedings of the Association in a "widely circulating medical journal."

Before the discussion of Dr. E. C. Seguin's paper was resumed, DR. EUGÈNE DUPUY made a few remarks upon

#### HEREDITARY TRANSMISSION OF PECULIARITIES.

It was a report of a curious case of heredity. Dr. Dupuy stated that he owed to his friend, Dr. Gibney, the opportunity of observing a family consisting of father and mother, five children, and one grandchild. The father and mother are semi-ambidextrous. All of the children and the grandchild are ambidextrous to an annoying degree: all of the movements which they perform with one hand are simultaneously performed by the other hand. The girls are obliged to use only one hand when dressing themselves, or when cutting patterns, and hold the other hand down by their side, because the two hands perform the same movements at the same time, and would interfere with each other.

Attention was called to the fact that the father of the grandchild is not semi-ambidextrous. Dr. Dupuy has made experiments upon these persons, and has found that, if the skin of the forearm on one side be kept well dry, and a rapidly interrupted electrical current be used, so as only to call forth reflex actions, it is possible to induce synchronous movements in the fingers of both hands, and also muscular contraction in the lumbricales muscles of the fingers, which are too rapid to be carried on by the will. Dr. Dupuy considered these facts of great interest when coupled with the facts which he reported yesterday about hereditary epilepsy.

DR. SPITZKA called for Dr. Seguin's views in regard to the subject of his last paper—Localization of Brain

Lesions—which was given, and an animated discussion followed.

MENTAL THERAPEUTICS IN ORGANIC DISEASE, AS ILLUSTRATED DURING THE BLUE-GLASS DELUSION.

This was the title of a paper read by Dr. GEO. M. BEARD, and was a continuation of one which he read last year before the Association, on "The Influence of Mind in the Causation and Cure of Disease."

Dr. Beard cited two cases of organic disease of the spine which had received decided temporary relief while sitting under blue glass.

The opinion was expressed that in time all works on therapeutics must include a chapter on mental therapeutics.

From experiments and study, Dr. Beard was able to make the following psychological suggestions:

1. The ill-success of patients treating themselves, and of physicians treating their own families, was partly due to the want of awe and the emotion of wonder to co-operate with them.

2. The old custom of keeping patients ignorant of the contents of prescriptions, by writing them in Latin, had psychology on its side. Possibly we may be going too far the other way.

3. It is entirely possible that hydrophobia and tetanus may be brought on, with all their distinctive symptoms, and that death may result through the emotions of fear and expectation alone.

4. Patients whose will and intellect are feeble have a bad prognosis, for with them the subjective symptoms are trifling; and *vice versa*.

5. Physicians of great scientific attainment and real worth may fail when an ignorant and obscure charlatan succeeds, because in the latter wonder and awe are excited, and these are more powerful therapeutically than simple respect.

6. In experimenting in hospitals with new medicines, patients must be deceived, or else the results are complicated by mental influence.

Dr. Beard expressed a belief that those who would repeat his experiments would confirm his results and conclusions.

This paper was discussed by Drs. Seguin, Miles, Beard, Cross, Jewell, and Dupuy.

It being very late, Dr. Jewell's paper on *Athetosis* was read by title only.

DR. JEWELL, in appropriate words, thanked the Association for the kind and generous way in which they had treated him.

At 10.30 P.M. the Association adjourned.

### ARMY NEWS.

*Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from July 8 to July 14, 1877.*

SWIFT, E., Lieut. Colonel and Asst. Medical Purveyor. Relieved from duty as Medical Director, Dept. of the Gulf, to proceed to New York City, and relieve Colonel C. Sutherland, Surgeon, of the charge of the Medical Purveying Depot in that city. S. O. 147, C. S., A. G. O.

STERNBERG, G. M., Major and Surgeon. Telegraphic instructions of 19th inst. to proceed with ample medical supplies, with Companies B and H, 21st Infantry, from Fort Walla Walla to Lewiston, Idaho Ter., confirmed. S. O. 86, Dept. of the Columbia, June 29, 1877.

BROOKE, J., Captain and Asst. Surgeon. To accompany 2d Infantry to Dept. of the Columbia and return to his present station, unless otherwise ordered. S. O. 133, Dept. of the South, July 7, 1877.

KINSMAN, J. H., Captain and Asst. Surgeon. Assigned to duty as Post Surgeon at Jackson, Miss.; S. O. 114, Dept. of the Gulf, July 4, 1877; and granted leave of absence for one month, with permission to apply for one month's extension. S. O. 116, C. S., Gulf.

DE HANNE, J. V., Captain and Asst. Surgeon. To accompany troops to Fort Clark, Texas, and report to the Comdg. Officer, District of the Nueces, for assignment. S. O. 125, Dept. of Texas, July 7, 1877.

ELBREY, F. W., Captain and Asst. Surgeon. To accompany 2d Infantry to Idaho Ter., and return to his present station, unless otherwise ordered. S. O. 133, C. S., Dept. of the South.

ADAIR, G. W., 1st. Lieut. and Asst. Surgeon. To report to Comdg. Officer, District of the Rio Grande, Fort Brown, Texas, for duty. S. O. 125, C. S., Dept. of Texas.

SEMG, B. G., 1st Lieut. and Asst. Surgeon. Assigned to temporary duty at Camp McDermot, Nev. S. O. 76, Div. of the Pacific and Dept. of California, June 29, 1877.

REED, W., 1st. Lieut. and Asst. Surgeon. Assigned to duty at Camp Apache, A. T. S. O. 66, Dept. of Arizona, June 26, 1877.

HALL, W. H., 1st Lieut. and Asst. Surgeon. Telegraphic instructions of 20th inst. to accompany troops on board steamer "California" to Lewiston, Idaho Ter., for field service, confirmed. S. O. 86, C. S., Dept. of the Columbia.

TORNEY, G. H., 1st Lieut. and Asst. Surgeon. Assigned to duty at Fort Gibson, Indian Ter. S. O. 125, Dept. of the Missouri, July 5, 1877.

GARDINER, J. B. W., 1st Lieut. and Asst. Surgeon. Assigned to duty at Camp Lowell, A. T. S. O. 66, C. S., Dept. of Arizona.

### Medical Items and News.

CONTAGIOUS DISEASES.—Comparative statement of cases of Contagious Disease reported to the Sanitary Bureau, Health Department, for the two weeks ending July 14, 1877.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-Spinal Meningitis.	Measles.	Diphtheria.	Small-pox.

BLOOMINGDALE ASYLUM, N. Y.—Dr. C. H. Nichols, who for twenty-five years has been Medical Superintendent of the Government Hospital for the Insane at Washington, D. C., has received a similar appointment for the Bloomingdale Asylum in this city, *vice* Dr. D. Tilden Brown, resigned in consequence of ill-health.

DR. NATHAN R. SMITH, of Baltimore, Md., died July 3d, in the eighty-first year of his age. He was born in Cornish, N. H. In 1825 he was appointed Professor of Surgery and Anatomy in the University of Vermont, and in 1827 he accepted the Chair of Surgery in the University of Maryland, which he filled for many years. Although an excellent surgeon and successful teacher, he was known principally in connection with his anterior splint for the treatment of fractures of the thigh.

## Original Communications.

## THE VALUE OF SMALL AND FREQUENTLY REPEATED DOSES.

By S. HENRY DESSAU, M.D.,

ONE OF THE DISTRICT PHYSICIANS TO THE N. Y. DISPENSARY, AND ONE OF THE PHYSICIANS TO THE OUT-DOOR DEPARTMENT OF THE N. Y. FOUNDLING ASYLUM.

(Read before the N. Y. Medical Journal Association, June 15, 1877.)

MR. PRESIDENT AND GENTLEMEN:—In response to the kind invitation of your Secretary, I have the honor to present to you the paper of the evening, on the subject of "The Value of Small and Frequently Repeated Doses." In doing so, I regret that my limited experience and lack of necessary facilities will not enable me to furnish you with any very new facts. The object of this paper is more for the purpose of directing your attention and consideration to a feature of the therapeutical art which has only recently received due recognition at the hands of some of our best authorities in this branch of medical study, and to invite your discussion upon its merits.

The scientific spirit that has marked the progress of medical study has encountered more difficulties in the domain of therapeutics than elsewhere, but it has at the same time engendered and cultivated a spirit of liberalism that pre-eminently entitles us to the use of the term eclectic. We winnow valuable facts from the chaff of our own and others' experience, and appropriate them to the advancement of the medical arts and sciences. In therapeutics especially the presentation of a new fact to the profession invites a series of careful, accurate, and thorough investigations and observations, that must tend to develop in the end a pathway that may lead us at some future time to that utopian goal—a scientific therapeutics.

Upon the appearance of that now indispensable little work, *Ringer's Handbook of Therapeutics*, my attention was particularly attracted to the frequency with which he recommends small doses of medicines, that we have been accustomed to use in much larger doses, for entirely different diseases. Some of these remedies were recommended so strongly that I was induced to give them a trial, more especially as my practice among children impels me, for many reasons, to administer as little unpleasant-tasting medicines as possible. Their use with children first having been found satisfactory, my position in connection with the New York Dispensary afforded me the opportunity to further test their value in numerous cases of adults. I submit the results of my experience in the use of these remedies to your consideration.

In the treatment of vomiting in children, whether due to stomach and intestinal disorder, or as a complication of pneumonia, following the recommendation of Ringer, I have found the administration of drop doses of the wine of ipecac, repeated every hour, act with the greatest success in checking the vomiting. It also appears to exert a curative effect upon the diarrhoea of children when attended with vomiting, especially that form where the stools resemble those of dysentery. But the vomiting is the symptom that is most markedly benefited. I recall the case of a little patient at the New York Foundling Asylum, suffering from a severe attack of croupous pneumonia, where the stomach was so irritable for the first two days of the attack that not even a spoonful of toast-water would remain. This condition, of course, prevented the retention of any remedies, but after the first dose of a

drop of wine of ipecac given in toast-water, the nurse reported that the vomiting entirely ceased and did not return. The remedy was, however, continued for two days longer. Frequently, where other remedies would not be retained in the vomiting of children suffering from acute gastro-intestinal catarrh, the drop dose of wine of ipecac, given in toast-water or the mother's milk, would remain and quiet the stomach to receive other remedies, and, most important of all, the mother's milk.

I have not had much experience with the use of ipecac in small doses in the treatment of vomiting in adults. I have used it in one case of chronic bronchitis with fibroid degeneration, subject to frequent attacks of vomiting, independent of the vomiting excited by the cough, but with not such good results as followed the small doses of other remedies that I will mention later.

In the vomiting sometimes following a debauch, especially in women, of which I have seen several severe cases, drop doses of Fowler's solution of arsenic, hourly repeated, appeared to act like a charm. This remedy is also highly recommended by Ringer in the morning vomiting of drunkards, where this symptom is indicative of a chronic affection of the gastric mucous membrane. Here the dose is not so frequently repeated, however, a drop of the solution given three times daily, before meals, being sufficiently often. Where there is a disgust for food, in addition to the morning vomiting, in these cases of chronic alcoholism, I have used a combination of a drop of Fowler's solution of arsenic and from three to five drops of tincture of capsicum, given before meals three times daily, with good success.

In the vomiting which often complicates phthisis pulmonalis and its allied affection, chronic bronchitis, independent of that brought on by the cough, it is of the utmost importance to be possessed of a reliable remedy to check it. The power of the stomach to retain its contents is here the only hope of any chance to strengthen and build up the general system, and so enable it to resist the encroachments of the disease-action. Moreover, the frequent attacks of vomiting tend to exhaust and weaken an already feeble organism, and so hasten dissolution. It is almost astonishing to observe with what happy success small doses of alum, say from three to five grains, given in solution with some aromatic water, as cinnamon, for instance, acts here.

When the vomiting in these cases is severe and frequent I have given the alum every second or third hour, but otherwise three times a day is sufficiently often. Rarely does the remedy need to be used beyond twenty-four hours. In a few cases that came under my observation, the vomiting, after having disturbed the patient for several days, has ceased after the second dose of the alum. This is the remedy that was used with such good effect in the case of chronic bronchitis before mentioned. For experimental purposes, hourly drop doses of wine of antimony were also used in this case, more especially as in certain attacks of the vomiting there was also an acute exacerbation of bronchitis, causing much dyspnoea, with wheezing respiration. The attacks of vomiting and dyspnoea appeared to be speedily relieved by this treatment, although it is fair to state that additional treatment, to produce sweating, was used to relieve the dyspnoea and wheezing.

After some children have passed through an attack of pertussis, especially those of a lymphatic temperament, they are apt to be harassed with a troublesome cough for many months, which appears to be a slow

winding up of the original disease, and is often so considered by the mothers. There is a certain amount of laryngeal spasm during the cough, which is liable to induce frequent vomiting. I have seen this condition existing in a severe degree in a child at the New York Foundling Asylum, a year after the original attack, and after the disappearance of the cough for an interval of several months. There is generally no great amount of bronchitis. In such cases I have used small doses of alum, one to three grains given in syrup of wild cherry three times daily, with the result of checking the vomiting speedily and relieving the cough of its spasmodic elements, if not curing it entirely. There is a form of bronchitis seen amongst children, where a large number of coarse mucous râles produce loud wheezing with an asthmatic quality of cough. The wheezing is the symptom that the mother is most likely to complain of, and together with the cough is most intense at night, both almost entirely disappearing during the day. Such cases very readily yield in my practice under the use of tartar emetic, given in solution in the proportion of a grain to the pint of water. Of this solution a teaspoonful is given every one or two hours, with the best results, sometimes, according to Ringer, relieving the noisy wheezing after one or two doses.

Often in children we find a catarrh of the bronchial and intestinal mucous membranes, either coexisting or alternating with each other. When such a condition persists after the employment of the ordinary household remedies, tartar emetic in the same doses of the solution just before mentioned, hourly repeated, will check both catarrhs without the use of further treatment. This plan is, at least, an advantage over the usual one of prescribing separately for the cough and diarrhoea. I am indebted to Ringer for the suggestions of the foregoing treatments.

In the treatment of syphilis we have come, as an almost universal rule, to rely upon the benefit of some form of mercury. That form most ordinarily in favor, in the earlier stages of the disease, is, I doubt not, the protiodide, and that in the more advanced stages the biniodide, in combination, perhaps, with iodide of potassium. Special symptoms will arise, however, during the progress of such treatment, or present themselves primarily for treatment, that do not appear to be immediately influenced by either of the forms of mercury mentioned. Such, for instance, is the cephalalgia that I have seen rack and torment the patient, in spite of large doses of chloral hydrate and bromide of potassium in combination, phosphorus, the hypodermic employment of sulphate of morphia, or even free doses of iodide of potassium, the patient in the meanwhile undergoing a course of mercurial treatment after the plan above mentioned. The iodide of potassium may, however, afford relief from the pain after a certain duration of time, but perhaps not until much exhaustion has been caused by the intense suffering.

It was after I had almost been baffled in dealing with such a case that I read in one of our journals, I think the *Medical News and Library*, an extract from a foreign journal upon the treatment of this complication in syphilis, by Dr. Peter, of Paris. He recommends the use of calomel in the one-sixtieth of a grain doses every hour until the pain is relieved. Coming from such respected authority, I determined to use this treatment at the first opportunity. The case presented itself in time and was a fair one to test the value of the treatment upon. No sleep had been obtained for three nights, and so great was the pain that there was complete anorexia. Before using a dozen of the pow-

ders, in which form the calomel was given, relief was obtained and sleep procured. In thirty hours the pain had entirely ceased, and no more powders were used. No signs of mercurial salivation were shown, and the appetite returned as soon as the pain was relieved. This result was a decided advantage over that obtained in another case from iodide of potassium, where it was at least three days before any relief was experienced from pretty free doses. No form of mercury had been previously used in this case, as the cephalalgia was the complaint that caused the patient to seek medical advice. Its syphilitic character was readily determined by the aid of other symptoms present and the history of the case.

A favorite treatment with many physicians in the summer diarrhoeas of children is calomel, either alone or combined with some adjuvants, given in varying doses. I cannot express much of an opinion concerning this treatment, though I doubt not it is of value, when the doses do not exceed a certain limit. I have, however, frequently had occasion to prescribe calomel in doses of  $\frac{1}{6}$  of a grain, hourly repeated, in the gastro-intestinal catarrhs of infants, especially where the vomiting was a troublesome element of the complaint, with beneficial results. It is a treatment that I first heard recommended by Prof. J. B. Biddle, of Philadelphia, when I was a student.

Following the suggestions of Ringer, I have lately given preference to mercury with chalk, as the form of mercurial to administer in the summer diarrhoeas of children. The usual dose is  $\frac{1}{6}$  of a grain, given either with sugar or with three to five grain doses of subnitrate of bismuth, hourly repeated. Trousseau recommends this preparation of mercury in catarrhal diarrhoeas, but in somewhat larger doses.

In a form of diarrhoea in children, likely to be mistaken for dysentery, but where the general symptoms are mild, and the special features are secondary to the diarrhoea, corrosive-sublimate will be found to render most satisfactory service in effecting a cure. The principal indication for the use of corrosive sublimate, according to Ringer, is the mucous character of the stools, whether containing blood or not. There may also be more or less straining at stool. I have used the corrosive-sublimate in such cases, in the proportion of a grain to sixteen ounces of water, which is half the strength recommended by Eustace Smith. Ringer recommends a grain to ten ounces of water. Of this solution, a teaspoonful is given every hour, or two hours, as the severity of the case demands. I have seen the character of the stools changed, and the number considerably reduced within six hours under this treatment. Hughes also recommends this treatment in his *Manual of Therapeutics*, a quasi homœopathic work.

Gonorrhœa may be said to be a specific catarrh of the urethra, where every practitioner has his own favorite remedy. This, of course, may depend upon the stage of the complaint, and other modifying circumstances. I here acknowledge my thanks to Prof. Ringer for his valuable suggestions on the treatment of this complaint, in his work so often quoted by me in this paper. When a case of gonorrhœa can be seen in the first twenty-four hours of the attack, as has been my good fortune in several instances, an injection of a solution of chloride of zinc, one grain to a pint of water, used every hour, will cut short the attack in twenty-four hours. I can bear testimony to this fact. My impression, from the trial of other remedies, is, that an important factor of this treatment is the frequency of repetition of the injection, especially when the agent is mild.

About a year ago, under the head of "Notes of Hospital Practice," there appeared in the *New York Medical Journal* a paragraph on the value of small doses of copaiba in urticaria, as employed by me at the New York Foundling Asylum. Two cases, both of which were of a chronic nature, were especially cited to illustrate the beneficial results of this treatment. In these cases, to repeat, the affection had existed for two or three months, unsubdued by the usual treatment of salines and purgatives, and afterwards of arsenic and iron. It occurred to me to prescribe drop doses of copaiba three times daily. The theory of the treatment was founded upon a desire to test the value of the *similia similibus curantur* principle. It was a purely tentative treatment with me, though I have since been informed that the same treatment for urticaria had been noticed in some of our numerous medical journals previous to the date of my cases. I have not been able to find any journal containing any information on such subject, and therefore modestly lay claim to the originality of the treatment. I am willing to surrender my claim whenever a worthier claimant for priority presents himself. These cases yielded most gratifying results, and since then I have treated numerous cases in children with a like success, as far as my knowledge of the result of those cases extends.

My main experience with the use of copaiba in urticaria has been amongst children, but I have had occasion to administer it in an acute attack in the adult. It was a severe one, following the eating of lobster-salad. It had persisted in its severity for three days and nights, before I began the use of the copaiba. Purgatives, saline diuretics and mustard foot-baths had been freely given in the meantime, without any perceptible improvement of the eruption. Drop doses of the copaiba were then given every hour, and in eight hours there was a marked diminution of the eruption, and the next morning it had entirely disappeared. It may have been that this result would have occurred spontaneously, but, following so closely upon the use of copaiba as it did, it appeared to me at least a remarkable coincidence, that justifies further trials of a similar treatment in future cases.

Two cases of retarded menstruation, occurring in healthy females, non-pregnant, and ordinarily regular, have been treated by me with drop doses of fluid extract of ergot, hourly repeated. The menses appeared within twelve hours after treatment was commenced. Both cases were only a few days beyond the regular time, not over five days, and there was no reason to suspect pregnancy, though both were in married women. There were some slight premonitory symptoms of an approaching epoch present in each case. In one of the cases the same treatment was employed a second time, one year after the first, with a like success.

Stillé mentions the employment of ergot in amenorrhœa, and quotes Ackerly, Dieu, and Néligan as reporting successful cases in its favor. The dose is not mentioned. Ringer merely refers to it as being recommended. Bartholow states that it has cured amenorrhœa due to plethora, but does not give the dose. In three cases of epistaxis of a severe degree—one apparently due to vicarious menstruation in a young nigger, the second probably due to a lesion of the cardiac valves, in a small girl, and the third likely complicated with the hemorrhagic diathesis, in a male adult—marked benefit was derived from the use of fluid extract of hamamelis given in five-drop doses three times daily. Ringer recommends drop doses of the hamamelis to be given every hour until the bleeding is checked, and then continuing it for a few days in five-drop doses, three times daily.

In one case of heat-flushing, occurring near the menopause, following Ringer I have used  $\frac{3}{30}$  to  $\frac{1}{15}$  of a minim doses of nitrite of amyl internally every three hours, and an additional dose on flushing. The amyl may be given dissolved in alcohol, two minims to the drachm, and of this three to five drops are taken on a lump of crushed sugar. The result in my case, after one week's treatment, appeared satisfactory, when further sight of the case was lost.

Upon one occasion, on the recommendation of Ringer, I have given a trial to drop doses of tincture of aconite, repeated at first every fifteen minutes for four doses, and subsequently every hour, for the purpose of reducing temperature. The case was a severe and painful attack of pharyngitis accompanied with high fever, occurring in an adult. It was in reality a defaced form of scarlatina, the specific character of which was not at first recognized. After eight hours' use of the aconite, as above described, the temperature was found moderately reduced. Other treatment was then adopted, and the aconite was discontinued. Ringer states, however, that it is doubtful whether aconite will shorten the fever of acute specific disease, as scarlatina, for instance. Bartholow, on the other hand, gives it the highest praise in scarlatina, especially in the eruptive and desquamative stages of the disease. I have lately found fifteen to twenty grain doses of salicylate of soda, hourly repeated, to produce the most gratifying results in the scarlatinal pharyngitis of adults, allaying the pain and reducing the fever in a very short time.

Aconite receives the highest recommendation, especially for the purpose of reducing temperature and checking inflammatory processes, from both Ringer and Bartholow. The latter speaks of this medicine as a powerful agent which will produce manifest results in small doses, the more frequent use of which in the general profession has been discouraged by a prejudice, on account of its favor with homœopathic practitioners.

Digitalis and belladonna receive considerable notice from the above-mentioned writers, for their valuable remedial virtues in small doses. On the subject of digitalis Ringer remarks: "In all treatment, the object should be to obtain the greatest therapeutical effects with the smallest possible dose of medicine. This is particularly important with a powerful drug like digitalis; for large doses sometimes appear to increase the heart's embarrassment, and relief comes only when the dose is diminished. Further, it is important not to give a larger dose than is necessary, since it is very likely the patient may require to take it for a long period, and, becoming accustomed to the medicine, the dose which at first did good seems partially to lose its effect and requires augmentation; but this could be done only with the greatest caution, and even then with some hazard, if the maximum quantity had been given in the first instance." Bartholow pronounces strongly in favor of belladonna as a cure for idiopathic erysipelas, especially when affecting the face. He also remarks its prompt action in acute nasal catarrh with profuse watery secretion, and in ordinary sore throat. He advises giving five drops of the tincture as a first dose and repeating with one or two drops every hour. Hughes regards belladonna as displaying wonderful powers in catarrhal throat affections.

Tincture of nuxvomica also appears, according to Ringer, to be possessed of real curative powers, when given in drop doses, repeated every five or ten minutes for eight or ten doses and then continued at longer intervals, for "sick headache" accompanied with acute gastric catarrh, whether due to error in diet, con-

stipation, or no apparent cause. He regards it, administered in small and frequently repeated doses, as useful in many disturbances of the gastric function. Cantharides, in the form of the tincture, has received a trial from me, in small and frequently repeated doses. The case was one where there was a frequent desire to urinate, only a small quantity of urine being passed, with much straining, each time. There was no evidence of a lithiasis nor gonorrhœa. The urine did not contain albumen nor blood. There was a small vesical catarrh of a subacute character. It had existed for three days. One drop of the tincture of cantharides was ordered every hour, and the next day the patient reported himself as immensely improved, and the second day as well.

Many other medicinal agents are mentioned by Ringer, Bartholow, and other writers, as being valuable and reliable in small and frequently repeated doses, in the treatment of various disorders. My friend, Dr. Geo. H. Fox, has informed me that he has witnessed decided beneficial effects from the use of small doses of pulsatilla in painful menstruation. Many of us have no doubt long been familiar with the use of small doses of castor oil in certain forms of diarrhœa in children. An every-day practice, that has become so common as perhaps not to attract our attention to the fact, is the large use of mineral waters for the cure of various dyspeptic and renal complaints. Here the actual dose of the supposed remedial salts has been shown to be quite small, the only one taken in any appreciable quantity being chloride of sodium, of which we use more in our daily food than is contained in a pint of most mineral waters.

It is a familiar fact, that the most successful treatment for acid dyspepsia now used in the daily practice of the medical profession is the administration of small doses of mineral acids before meals, and for promoting an increase of the acid of the gastric juice, the administration of alkalis before meals.

Dr. Edward Vanderpool, of this city, in an article on strychnia in tetanus and hydrophobia, published in the *Medical and Surgical Reporter* of May 7, 1870, refers to eight cases of tetanus, seven traumatic and one idiopathic, coming under his care, which he cured with rather large doses of strychnia, giving  $\frac{1}{4}$  to  $\frac{1}{2}$  of a grain every two hours until relaxation of the muscles took place, when the interval was extended to every six hours. He states that he published full reports of these cases in the *New York Journal of Medicine*, Nov. and Jan. Nos. for 1846 and 1847. Hughes quotes these cases in his *Manual of Therapeutics* to prove and substantiate the doctrine of the law of similars. Such remarkable success in such a usually fatal disease ought surely offer encouragement to therapeutists to investigate the action of strychnia in tetanus. If any substantial virtue should be found in the treatment in all probability smaller doses of such a deadly poison might prove to yield equally brilliant results.

The illustrations I have here offered of the value of small and frequently repeated doses might, from their general tone, lead one to infer that I was favorably inclined towards the homœopathic principle. But such is not the fact. I have had too many satisfactory demonstrations of the undoubted efficacy of full doses of medicines in the treatment of certain diseases to allow me to confine my belief in therapeutics to a single principle, as yet known.

While the small doses of the medicines mentioned in this paper have been found so useful, I have also been at times filled with an exultant pride at my success in the treatment of acute dysentery with  $\mathfrak{ss}$ . to  $\mathfrak{ij}$ . doses

of ipecac, one dose usually effecting a complete cure; or the rapid cure of acute articular rheumatism with large doses of salicylate of soda; the happy effect produced by chloride of potash in the ulcerative stomatitis of children; the almost specific action of quinia in intermittent fever; and the wonderful influence of tablespoonful doses of tincture of digitalis in delirium tremens.

If, then, I am asked to explain on what principle these small doses act in certain diseases, I reply, on the principle, so far as known, of actual experience (!) This is all we know about it. The homœopaths claim that it is explained by the law of similars, which is no explanation at all; and they pretend to make universal application of this so-called law in the treatment of disease. Trousseau, and Bartholow following him, attribute to it a substitutive action, or, as the latter writer expresses it, the therapeutical action is the physiological antagonist of the disease-action. If I might be so bold as to offer a theory of the action of small doses in the treatment of certain diseases, which in the totality of their symptoms and pathological processes correspond in a measure to the ultimate physiological action of the drug employed, I would submit the following:

Certain medicines in their physiological action manifest a primary stimulative and a secondary sedative effect. By primary stimulative effect I mean the action of the medicine when given in the smallest dose capable of producing appreciable results; and by the secondary sedative effect, the physiological action carried to and beyond the poison line. Opium, for instance, in small doses, is known to act as a stimulant, inducing wakefulness, while in ordinary ones it acts as a sedative narcotic. Alcohol, in small doses, is a general stimulant, while in large ones it is a general sedative. Aconite, in its action upon the heart, in small doses, slows the pulse by its irritative or stimulant action upon the origin of the pneumogastric in the medulla, while in large ones it increases the frequency of the pulse by its paralyzing or sedative action upon the pneumogastric. Upon the authority of Bartholow, camphor manifests one of its stimulant effects in small doses, by increasing sexual appetite, while in large doses it acts as a sedative or antaphrodisiac. In the therapeutical application of the primary stimulative effect of certain medicines, we aim at the same end we accomplish when we use the antiphlogistic touch of nitrate of silver to an ulcerated surface to hasten the healing process, or use a weak solution of sulphate of zinc to cure conjunctivitis. What the intimate nature of this therapeutical process is we do not know.

In attempting to explain the therapeutical action of medicines, I agree with Stillé, who says that "whatever else they may do, experiments upon the healthy organism can never fully reveal the manner in which medicines cure disease, because in the latter case an element is involved which does not exist in the former."

In regard to the frequency of repetition of the ordinary dose, it is always necessary to bear in mind the disposition of the remedy to prolong its effects and the average time in which it is eliminated from the system. In respect to the repetition of small doses, this may be important with only a few remedies, as for example, digitalis and belladonna. It will, I think, be found that the necessity for the frequent repetition of the small dose will be in direct ratio to the acute or chronic character of the complaint. Hourly doses will be best indicated in acute cases both to impress the disease quickly and maintain th

effect of the remedy; while in chronic cases a more chronic treatment is advisable.

The use of small doses whenever found advantageous may possibly lead to a general investigation of our pharmacopœia, with a view to the employment of the smallest quantity of those drugs, now used in large doses, capable of producing therapeutical results. It might be found safe to reduce the dose of many disagreeable-tasting medicines, as the muriate of ammonia, for instance, without impairing their valuable properties; and other valuable remedies likely to be followed by evil results, when given in large doses, might be found all the more valuable when used in smaller ones. It would certainly tend to elevate the standard of medical science in the minds of mothers and delicate invalids, and, at the same time, and above all, assure the physician that there was not so much danger as now of the features of the disease being obscured by the action of the remedy.

The use of small doses, as indicated in this paper, will also no doubt often afford the physician valuable service in relieving many obscure cases where the principal complaint is one or a certain group of symptoms that do not point to any discoverable lesion.

TABLE CONTAINING 96 CASES OF VESICAL AND URETHRAL CALCULUS,

UNDER THE CARE OF

PROF. GEORGE E. POST, M.D.,

OF THE SYRIAN PROTESTANT COLLEGE, AT BEIRÛT, SYRIA.

1. Vesical and perineal stones removed by perineal section in the male.

\* The operation known as Post's operation is a modification of the bilateral in which the incision of the prostate is made with a gorget invented by Prof. Alfred C. Post, M.D., of the University of New York. This instrument consists of a canula sliding over a stout wire which has a probe point fitting the groove of the median staff. The distal extremity of the canula is conical, and on either side is a groove into which slides a half triangular blade. When the two blades are adjusted they define the incision to be made with accuracy. The proximal extremity of the canula is furnished with a handle. The mode of using the instrument is as follows: The usual incision having been made as in bilateral lithotomy, and the median groove of the staff having been exposed, the probe point of the guiding wire is introduced into the groove and carried on to the bladder. The staff is then withdrawn. With the guiding wire the stone is felt with ease, and the canula is slid along it with perfect precision into the bladder. The peculiarity of the gorget is the impossibility of slipping, and the perfectly definite incision which it makes. Different sizes of the blades suit the various sizes of the stones requiring operation. Of the safety of this instrument in the hands of a young operator, no better proof can be offered than the fact that Dr. Meshaka, of Damascus, one of the graduates of the medical school at Beirût, has operated 47 times with this instrument without a fatal case.

† The case No. 1 was that of a Moslem suffering from the exhaustion of a long cystitis; the unusual size of the stone, over 4½ ounces, and its exceedingly rough surface, caused more than usual injury to the neck of the bladder. The surface of the stone was covered with spicule a quarter of an inch in length. The close contraction of the bladder on the stone prevented lithotomy.

‡ Case No. 6 presented the following features: The prostate was unusually large, and the bladder deep in the perineum. No unusual hemorrhage accompanied or followed the operation. The stone was concavo-convex in shape, greenish in hue, with stalactitic roughness of the edge, which was quite sharp and jagged. No untoward symptom occurred during nor after the operation until the fourth day, when he had sudden very copious diarrœa, by which he was greatly

reduced in strength. On the sixth day he began to be troubled with a cough and hiccnghis; the temperature on the fifth day was 103° F., evening. The following morning it was 101° F. From that time the pulse rose steadily ¼° F. every twenty-four hours to the twelfth day, when he died with symptoms of pneumonia.

At the autopsy the right pleural cavity was found full of old adhesions, and the lower lobe of the right lung was hepaticized. The lower lobe of the left lung was congested, but not hepaticized. Heart normal. Digestive organs sound. Bladder contracted in the shape of an hour-glass, and its walls greatly thickened, especially at the base, where the thickness was two-thirds of an inch, and the mucous membrane ulcerated and much corrugated.

The left ureter was somewhat dilated near its point of entrance into the bladder, but opposite the primitive iliac artery it had become reduced to a fibrous cord. Following this cord to the place where the kidney should have been, no kidney appeared. After much search, a body resembling a kidney-bean in size, shape, and color, was found with the attenuated remains of the ureter attached to the place where the pelvis had been. This diminutive body was the remains of the fibrous connective tissue of the atrophied and vanished viscus. The opposite ureter was much dilated and tortuous, resembling the small intestines, and led to a much hypertrophied kidney, the pelvis of which was widely dilated, and the mucous membrane ulcerated. Granulations and ulcerations were found even to the extremities of the infundibula.

\* In this case the prostate was very much hypertrophied and rigid, being cut with difficulty, and the bladder distant from the surface. The stone, which was a small one, sealed off from the mucous membrane, leaving an adherent sabulous layer which could not be wholly removed by the scoop. The death was caused by exhaustion from tenesmus of the bladder.

\* This case was one in which a chain of stones, six of which were about the size of a medium-sized pea, and the seventh (the most anterior) the size of a small filbert. This chain occupied the membranous portion of the urethra, projecting anteriorly into the bulb, and posteriorly into the prostate. Its length was one inch and three-quarters. The adjacent surfaces were worn into facets resembling the adjacent faces of the caudal vertebra in animals.

† In this case the patient had been the victim of a vesical stone in infancy, and was operated on by a professional Arab stone-cutter by the recto-perineal method without staff. The result was a recto-urethral fistula communicating with the perineum anterior to the sphincter ani. Into a pouch of this fistula the faeces, containing grape and lentil seeds, appear to have entered, and around these as a nucleus were formed the above-mentioned number of stones. Of these the central one, which is of the shape of a Prince Rupert's drop without the terminal hook, is three inches in length. The blunt end presented anteriorly, and the sharp end projected backwards to the neck of the bladder. This stone weighed 68 grammes. On its surface are many facets in which were smaller concretions, the combined weight of which is about 2 grammes. The total number of concretions is sixty-five, all of them formed around seeds as above mentioned. The stones were removed by a simple perineal section, and the walls of the sac thus left removed to the depth of the urethra. Unfortunately the patient left the hospital before the fistula had closed, and has not since returned.

‡ This patient, during the second session of the lithotripsy, twisted his ankle. He allowed it to be seen by an ignorant woman, who pronounced it dislocated, and "set" it. Severe inflammation of the joint supervened, followed by necrosis of the astragalus. The severity of the inflammation was such that at one time his life was despaired of. Notwithstanding this intercurrent accident, and the persistence of the cystitis, the patient survives, and at times experiences relief from the tenuesmus. No concretion has collected again in the bladder.

*Stones in Females.*

**COOK COUNTY HOSPITAL, CHICAGO.**

SERVICE OF PROF. HENRY M. LYMAN, M.D.

**A CASE OF PNEUMO-PYOTHORAX WITH EXTENSIVE CASEOUS INFILTRATION OF LUNG FOLLOWING PLEURITIS.**

J. T., a colored man, 23 years old, was admitted March 1, 1877. He was a stout and vigorous-looking man, and said he had been working in the hold of a ship and had caught cold several times of late. Two weeks before, he began to cough, and a week before, he had expectorated for two days bloody sputa.

About this time he caught a fresh cold, had cutting pains in the right side, and was obliged to quit work. Fever had come on, with thirst, scanty and high colored urine. He now found it impossible to lie on the right side, and sleep was prevented by pain in the right mammary region, and constant cough. His appetite had been good and the bowels had been regular; the tongue was clean.

Moist râles were discovered over the right chest posteriorly, while in front friction sounds were heard.

His case was regarded one of pleuritis, and he was put to bed with a large poultice over the right side; a ten-grain Dover powder was ordered for each night, and a muriate of ammonia mixture every four hours.

By March 6th he had greatly improved, and the poultice was discontinued. There was now no pain, and the patient ate and slept well. The chest was ordered painted regularly with tincture of iodine. In two days more the friction sounds had disappeared entirely, as well as the râles.

March 10th, there was an exacerbation, in which friction sounds were detected over the whole of the right chest as well as dry and moist râles throughout the right lung. Fever again appeared and all the previous constitutional symptoms.

On March 23d, convalescence seemed again established. The friction sounds were gone, as well as mostly the râles. A slight sonorous râle was heard here and there, but there was no evidences of effusion. The paintings with tincture iodine had four days previously caused blistering and been discontinued.

Things went on smoothly until April 2d, when a

\* In this case the stone consisted of a nucleus, the size of a hickory-nut, and of a soft, friable cortex, which broke down under the forceps. Much sabulous matter lined the bladder, and required to be scraped off by a scoop. The patient seemed to be doing well until the twentieth day. On the nineteenth day she had asked leave to return to her home, but was advised to remain a few days longer. On the twentieth day she had sudden symptoms of perforation of the bladder, and died within twelve hours. No autopsy was permitted.

new set of signs are recorded. Now there was found dulness over lower portion of the right chest, extending nearly to the lower angle of scapula, with a faint vesicular murmur and diminished vocal resonance over the dull region. Pain and soreness were complained of in the part. He was given digitalis and squills in powder, and improved so that on April 14th the record was made that examination revealed no lesion.

About April 14th, however, he began again to suffer pain in the right side. April 16th, he was evidently much worse; his pulse was 132, temperature  $103\frac{1}{2}$ ° F., and respiration 44. April 17th and 18th, the pulse was 140, respiration 40, and temperature  $101$ ° F. Bronchophony, bronchial breathing, and increased fremitus were found over lower part of the right chest; this region was dull on percussion. Tincture of iodine was again painted over the affected region, and it was covered with oil-silk; quinine was given in liberal tonic doses (gr. iij. every four hours), and, three days later, a half ounce of whiskey was added to each dose of quinine.

The man continued in much the same condition, the signs of lung lesion not abating until May 12th, when cod-liver oil was ordered, a half ounce three times daily.

Examination on May 17th revealed, in addition to previously existing signs, amphoric breathing and voice over the lower part of the right chest posteriorly. Succussion gave a swashing sound in this neighborhood.

Aspiration was performed below the sixth rib under the axilla, a small quantity of pus being secured.

Patient died May 22d.

*Necropsy*, 30 hours after death. About a quart of sero-pus was found in the right pleural cavity. The lung was considerably contracted, and was filled thickly with masses of caseous matter—the masses varying in size considerably.

At about the centre of the surface of the lung, vertically, there was an opening from a cavity within the lung to the pleural cavity outside. This opening was immediately beneath the axilla, and was of the size of a goose-quill.

The entire pleural cavity was lined with a thick pyogenic membrane.

The opposite lung was healthy. No lesion was found in the liver, kidneys, or intestines.

Prof. Lyman, in a clinical lecture, said he regarded this case as one of caseous pneumonia, induced by the long continuance of a purulent pleuritis, and by prolonged compression of the lung. The first pleuritic effusion was undoubtedly not pus, but serum.

The opening in the side of the lung was made by the ulceration and enlargement of a cavity in the lung of considerable size, made by softening and liquefaction of one of the caseous masses.

#### A PECULIAR CASE OF EMPYEMA, WITH DEPOSIT OF MILIARY GRANULATIONS UPON THE PERITONEUM LINING THE DIAPHRAGM.

A. B., *æt.* 22, was admitted with acute pleuritis of right side. The effusion was considerable. Acute symptoms subsided, but fluid remaining, aspiration was performed after several weeks, and six ounces of serum, with no admixture of pus, was drawn off.

The patient did not improve, but grew worse, became very weak, and soon passed into a typhoid state: the chest partially refilled with fluid, and death occurred four weeks after the aspiration. The operation was not repeated, owing to the typhoid condition. There was at no time any sign of disease of either lung or of the bronchial tubes; there was no cough.

A necropsy showed the right pleural cavity half full of sero-purulent fluid. Flakes of purulent lymph were loosely attached to the pleural surface everywhere in the right chest. The lung was condensed, but healthy.

The abdominal organs were all healthy. Miliary granulations were found thickly studding the peritoneum of the inferior surface of the diaphragm at the part where it overlies the liver and where it covers and passes behind the spleen. The surface of peritoneum thus filled with the tubercles was about the size of a man's hand on each side. A few granulations were found in that part of the peritoneal covering of the liver and spleen lying against the granular surfaces of the diaphragm. A careful search for miliary tubercles elsewhere in the body failed to discover them in any other organ or part.

Dr. Lyman was of opinion that this case—because of the undoubted development of miliary tubercles following a purulent inflammation of the pleura—lent color to the theory that this species of tubercle is always due to the resorption of matter from cheesy foci.

## Progress of Medical Science.

TREATMENT OF INTUSSUSCEPTION BY ABDOMINAL SECTION.—In an article on this subject Prof. H. B. Sands embodies the history of a case in which the operation of laparotomy proved successful. The patient was an infant, six months of age, and was seen twelve hours after the symptoms began. She was then in great pain, and in a condition approaching collapse. There were vomiting and severe tenesmus, which was attended by the escape of bloody mucus from the rectum. The evacuations contained no feces. On palpation an elongated tumor could be felt, extending from the left iliac to the left hypochondriac region. On rectal examination the invaginated intestine was at once discovered, reaching down nearly to the anus, and filling the rectum completely. By conjoined manipulation the continuity of the rectal with the abdominal tumor could be distinctly appreciated. Several attempts were made to effect reduction by pushing up the rectal tumor with the finger, by inflating the intestine, and by the injection of warm water. These measures caused the abdominal tumor to disappear, so that it could no longer be discovered by palpation, but an examination by conjoined manipulation convinced the Professor that a certain portion of the intestine was yet unreduced. The abdomen was then opened by an incision two inches in length, below the umbilicus, and after some delay a tumor was found in the right iliac fossa, which proved to be the intussuscepted mass. On withdrawing it from the abdomen, it was found to be an intussusception of the cæcum and terminal portion of the ileum into the commencement of the ascending colon. On account of the rigidity and swelling of the intestinal coats, which were dark colored and ecchymotic, the disinvagination was difficult. It was effected mainly by pulling the outer or ensheathing layer of the intestine downward, and by squeezing the lower end of the intussuscepted gut. Considerable force had to be used. The wound was closed by five silver sutures. The pain, vomiting, tenesmus, and discharge of bloody mucus ceased immediately after the operation, and the bowels moved naturally on the second day. The subsequent recovery was complete.

After briefly describing the varieties and symptoms of intussusception, and analyzing the statistical tables

of the operations of abdominal section that have been performed for its cure. Prof. Sands closes his paper with the following deductions:

1. The success which has already been obtained in the operation of abdominal section for intussusception is sufficient to justify its repetition, when other means have proved unavailing.

2. There is reason to believe that in intussusception, as in strangulated hernia, the great danger lies in delay, and that, in acute cases, the operation, to be successful, must be performed at a very early period, probably within twenty-four hours from the invasion of the disease.

3. In chronic cases the operation is indicated when other means have failed, and there is reason to think that the invagination is still reducible.

4. It has been proved by the case herewith related, that the operation may succeed in acute cases, if performed during the first eighteen hours.

5. The greater fatality of the operation in infants has been shown to be rather apparent than real, and it remains to be proved whether in them, the performance of abdominal section for intussusception may not yield gratifying results.

6. In infancy the operation is more justifiable, because during that period, there is hardly any tendency toward spontaneous recovery after sloughing of the intestine.—*New York Medical Journal*, June, 1877.

**SIMPLE DILATATION OF THE STOMACH IN CHRONIC DYSPEPSIA.**—At a recent meeting of the Société de Biologie, M. Leven presented the stomach of a man, who died while under his care, presenting all the symptoms of a cancer of this organ. For a long time he had suffered at intervals from black vomit, had lost flesh, and shown all the signs of gastric cancer, or certainly ulcer. M. Leven, having recognized that he was simply troubled with a chronic dyspepsia of long standing, with great dilatation of the stomach, treated the case by means of the stomach-pump. He removed a very large quantity of fluid, and directly afterwards the patient, feeling his pains no longer, begged for something to eat. Thus he was able for some time to take nourishment without vomiting. Unhappily the cachectic state was already so far advanced that this treatment, while ameliorating his condition, did not restore him to health. He died, and at the autopsy it was found that the stomach was free from any trace of cancer or ulceration. On the posterior surface great dilatation of the blood-vessels was found, as occurs in chronic dyspepsia with simple dilatation. M. Leven states that a large number of patients are thought to have gastric carcinoma when it is simply dilatation in connection with dyspepsia. He has a number of cases to support this statement, and he thinks the stomach-pump may, by its appropriate use, save life.—*Gaz. de Hôpital*, May 8, 1877.

**FISSURES OF THE ANUS CONSECUTIVE TO AN OLD ECZEMA.**—A woman was recently admitted into the *Hôpital de la Charité* under the care of M. Gosselin, giving a history of acute and very intense pains after defecation, which had persisted for two months and a half. The pains were not accompanied by obstinate constipation, or by any vaginal or urethral discharge. The patient was anesthetized, and an examination revealed four or five erosions around the anus. The erosions were red, granular and not elevated, and extended in the form of rounded cracks, five or six in number, for a short distance into the intestine. There was no contracture of the sphincter. The skin around the erosions was thickened and grayish, and the appearances presented by it were

similar to those observed in cases of erythema and eczema of the anus. The diagnosis was multiple erosions consecutive to an old eczema, and probably excited by scratching with the nails. M. Gosselin performed forcible dilatation of the sphincter, with a view to facilitate the passage of fecal matters by enlarging the passage through which they escaped. Small pledgets of charpie, coated with the ointment of rhatany, were then introduced into the rectum, and applied especially to the points of solution of continuity. The excoriated surfaces were covered with rice powder.—*Gazette des Hôpitaux*, May 24, 1877.

**TREATMENT OF HYDROPHOBIA BY OXYGEN.**—A girl, seven years of age, was bitten by a rabid dog. The wound, which involved the subcutaneous cellular tissue, was at once cauterized with nitrate of silver and healed completely in seven days. The child had suffered three months previously from diphtheria, which had left a paralytic aphonia. When the wound had healed the child became very excitable. Seventeen days later dyspnoea suddenly manifested itself. The inspirations were free, but expiration was difficult and interrupted. Deglutition was almost impossible; the pulse was rapid and the fingers contracted. Neither urine nor feces were passed for forty-eight hours. The child inhaled three cubic feet of oxygen, which relieved the symptoms in two hours and a half. The next day a more severe attack occurred, with spasm of the muscles of the back and limbs, spasmodic respiration, and complete insensibility. These symptoms were again removed in three-quarters of an hour by the inhalation of oxygen. The slight dyspnoea which remained was treated in the same manner with oxygen for ten days, and the child made a complete recovery, with the aid of the monobromate of camphor, which was continued for two weeks.—*Wratschebuija Wedomosty*, No. 36.

**ON ACUTE POISONING BY SALICYLATE OF SODA.**—Dr. Petersen reports the case of a girl, fifteen years of age, who was given by mistake twenty-six grammes (nearly seven drachms) of salicylate of soda between six A.M. and six P.M., or twenty-two grammes between twelve M. and six P.M. Fourteen days previously the patient had undergone a resection of the ankle-joint for chronic fungous arthritis. Some of the symptoms of poisoning were different from those described by other writers. The patient's psychical condition was very striking—perfectly rational periods alternating with manifestations of insanity of a sombre character. This condition gradually disappeared in about eight days, the rational periods gradually becoming longer. The temperature had no influence on the psychical disturbances. After her recovery, the patient remembered nothing that had happened during this entire period. In her rational intervals she complained of severe headache, ringing in the ears, deafness, and impairment of vision for distant objects. For three or four days there were strabismus divergens and marked midriasis; for four or five days there was hoarseness, but as a laryngoscopic examination could not be made, Dr. Petersen is unable to say whether it depended on a laryngitis or on paralysis of the vocal cords. The respiration was rapid (forty per minute), but inspiration was quite deep. The pulse varied independently of the temperature, being at one time between 120 and 130, and at another between 80 and 90. The salicylate of soda did not in this case exert a prompt influence on the temperature. Circumscribed spots of vascular dilatation, which changed their position from time to time, were observed on the face, neck, breast and leg; these lasted for three days. A bed-sore rap-

idly formed on the sacrum, and was ascribed by Dr. Petersen to the vaso-motor disturbances. There was vomiting, but no gastric pains; no diarrhoea, but a very fetid smell to the faeces. The urine contained at first one-fifth per cent. albumen, which gradually disappeared. There was no oedema of the legs. The treatment was symptomatic. Bromide of potassium was administered. During the subsequent two weeks traumatic erysipelas set in on two occasions, but was arrested by subcutaneous injections of salicylic acid. After the last injection, symptoms of poisoning (redness of face, dilatation of pupils, frequent respiration, pulse of 130, etc.) set in, although the dose administered was very small (6 grms. solution=2 ctgrms. acid).

In two cases of very painful coxitis Dr. Petersen administered salicylic acid internally with benefit. In three other cases of erysipelas he also obtained very favorable results from subcutaneous injections of one gramme of a concentrated solution of salicylic acid.—*Centralblatt für Chirurgie*, May 5th.

**A NEW METHOD OF CURING POPLITEAL ANEURISMS.**—Dr. Martin Burke, of Bellevue Hospital, reports three cases of popliteal aneurism, that were cured by compression of the femoral artery by means of a conical bag filled with shot, which was suspended from a height in such a way that the apex of the cone pressed on the artery in Scarpa's triangle. In the first case pulsation in the aneurism ceased in eight days; in the second, in sixteen days; and in the third, in six days. The cure was slow in the second case, on account of the patient's neglect to keep the apparatus in place. During the treatment little or no pain or uneasiness was complained of in any of the cases.

The shot-bag was made of canvas, in the form of a flattened cone, the apex measuring one inch in diameter. A rounded piece of cork or India-rubber, one inch in thickness, was fitted accurately into the apex of the cone, and a long thin rod reaching down to and resting on the rubber or cork was then inserted and held in the middle of the cone while the shot was poured around it, until the bag weighed about twelve pounds. A piece of canvas, with a hole in the centre for the passage of the rod, was then stitched over the base of the bag, and a stout wire hook fastened to its centre. The bag was suspended to a pulley in the ceiling by means of a rope, with which it was connected by a piece of rubber tubing and a large-linked chain. The tubing made the apparatus elastic, and the chain enabled the Doctor to regulate more easily the amount of pressure employed.—*New York Medical Journal*, June, 1877.

**REMOVAL AND REPRODUCTION OF THE ENTIRE CLAVICLE.**—Dr. Porquet, of Vire, reports the following interesting case: A strong, healthy countryman, 19 years of age, was suddenly, and without known cause, seized with a violent pain in the right shoulder, on November 1, 1864. The pain and fever were intense, and for four or five days he was delirious. An abscess soon appeared over the outer end of the clavicle, which discharged for four months. In July, 1865, this abscess reopened, and a second one formed at the sternal end of the bone. Voluminous fungous growths were developed in both abscesses. These fungosities were destroyed by cauterization, but the suppuration continued, and destroyed a small portion of the skin, exposing about three centimeters of the bone. In November the patient consented to an operation; an incision was made parallel to the clavicle, and the bone was removed entire without difficulty. The wound was dressed simply, no apparatus

being employed. The suppuration was at first very abundant, but at the end of three months cicatrization was complete. The removal of the clavicle had left a considerable depression at the upper part of the chest, but this gradually filled up, and by September 1, 1866, *nine months after the operation*, a new clavicle had been almost completely reproduced. Except for 15 days at the beginning of his disease, and for 24 hours after the operation, the patient was never confined to his bed; he worked and used his arm both before and after the operation, performing all the hard work that a farmer is called on to perform. To-day there is no deformity of the chest and no trace of the affection, except a cicatrix, which is not very marked.

The clavicle, which was removed, was carious at the two extremities, but intact in the centre. A small portion of the sternal articular surface was still left.—*L'Année Médicale*, May, 1877.

**PRIMARY CANCER OF THE VERTEBRAL COLUMN.**—On October 14, 1876, a woman, aged 50, was admitted into the *Hôpital Cochin*, complaining of a severe pain in the left hip, which had set in suddenly a few days before. There was nothing about the patient to give rise to the suspicion of the existence of any diathesis. Shortly after her admission she had a severe attack of intercostal neuralgia on the right side. On December 15th she began to have fever, and was seized with intense pains all over the body, accompanied by great hyperaesthesia; the slightest touch caused pain. On the 20th, she began to have attacks of dyspnoea. From the 25th she lay with her head drawn backwards, and constantly groaning; her lips and tongue were dry, but the hyperaesthesia continued. She remained in this condition until the 3d of January, when death took place. The pulse varied between 120 and 130, and the temperature between 102½° and 104½°.

At the autopsy numerous cancerous nodules, varying in size from a hazel-nut to a walnut, were found in the lumbar and dorsal vertebrae. The cancer was of the encephaloid variety. The cord appeared more diffident than normal. Small cysts were found in the arachnoid, at the points of exit of the roots of the nerves. None of the other organs contained any traces of cancer. The left hip presented the lesions of a commencing arthritis sicca. On the posterior surface of the neck of the femur there was a small, hard nodule, developed from the periosteum, which may possibly prove to be cancerous. If so, its small size would indicate that it was secondary to the deposits in the vertebrae.—*Le Progrès Médical*, May 12th.

**A CASE OF HEMIMELIA.**—A man, aged fifty three, who died of phthisis in the *Hôpital Temporaire*, in last March, presented a congenital malformation of the left arm, which belonged to this rare class of deformities. None of his family were affected with any analogous deformity. The left forearm was absent, or rather was represented by a conical stump only four inches long. The arm was less voluminous, and an inch and a quarter shorter than the right arm. The stump could be moved, and during life the patient had been able to raise considerable weights with it. On removing the skin and fascia, all the muscles belonging to the outer side of the forearm were found, but they were very small. The long supinator was inserted into the lower end of the bone which represented the radius; the short supinator was normal, and the radiales were inserted into the skin at the summit of the cone. Of the muscles of the anterior

brachial region only the flexor carpi ulnaris and the flexor digitorum existed, both of which were inserted into the skin. In the posterior brachial region the extensor digitorum was found, which was inserted into the skin, and the extensor carpi ulnaris, which was inserted into a small movable bone at the inferior extremity of the ulnar. This probably represented the fifth metacarpal bone. The biceps was inserted into a tubercle situated in the usual site of the tuberosity; hence the movement of supination had been possible during life. Two small tubercles on the inner border of the stump were connected with the ulnar by a fibrous cord.

It is evident from the description that the malformation was not due to a spontaneous, intrauterine amputation; the presence of the terminal tubercles is enough to prove that. The brain and cord presented no lesion that could be discovered with the naked eye.—*Le Progrès Médical*, June 2d.

**COMPLETE OBLITERATION OF THE COMMON ILIAC VEINS AND THE VENA CAVA ASCENDENS, WITHOUT ŒDEMA.**—On February 1, 1877, a man, aged 56, was admitted into the *Hôpital Temporaire*, suffering from a strangulated inguinal hernia. The hernia had existed for twenty-five years, but had always been reducible until two days before his admission into the hospital, since which time he had passed neither faeces nor gas through the anus. As taxis proved unsuccessful, herniotomy was performed ninety-six hours after the beginning of the strangulation. It was found necessary to open the sac, and two loops of intestine, one ten inches in length, were found in it; the latter was violet in color, and had lost its polished surface. The reduction was easily performed. The operation was followed by a slight attack of peritonitis, but six days afterwards a marked improvement set in. The patient, however, suffered during the month of February from an obstinate diarrhoea, and from chills and elevations of temperature, attended, as a rule, by abdominal pain. In March, dyspnoea was added to the other symptoms, and on March 14th the patient died, apparently from failure of respiration.

At the autopsy, the neck of the sac was found to be obliterated; the intestines were congested, and presented some adhesions. In the true pelvis there was a cavity which was closed above by loops of intestine and by mesentery, and which contained a blackish, fetid fluid. The loop of intestine that had constituted the hernia was perforated in three places. The gall-bladder was surrounded by a collection of pus, which was retained in position by adhesions between the duodenum, the transverse colon, and the omentum. There were no abscesses or infarctions in any of the viscera. The lungs were congested at the bases; heart healthy. The internal and common iliac veins and the vena cava ascendens were filled with a clot, which obliterated them entirely, and extended as high as the renal veins. The internal surface of the vena cava was intensely red, as high up as the upper end of the clot. The clot possessed a fibrous envelope, smooth and dark red on its outer surface, irregular on the inner. In the centre there was some grayish-red, semi-fluid matter, forming a sort of false pus. In the common iliaes the clot was also softened in the centre; in the lower part of the left iliac vein it was compact and presented whitish, fibrinous lamina, separated by irregular dark-red masses. The lumbar veins were also obliterated by fibrinous clots.

The strange point in this case was the obliteration of the iliac veins and the vena cava ascendens, because during life there had been no symptoms to indicate

this serious lesion. There had *never* been any œdema of the lower limbs. The subcutaneous abdominal veins were not abnormally dilated, and it has already been stated that the lumbar veins, at least in the immediate vicinity of the vena cava, were obstructed. The only case on record which is at all analogous to this is one reported by Castellan, in which an almost complete obliteration of the vena cava ascendens, as high up as the liver, had only produced slight œdema of one leg. In the case here described, the only explanation of the absence of œdema is to be found in the fact that the patient being cachectic and depressed, the circulation was very slow.—*Le Progrès Médical*, June 2d.

**HYPODERMIC INJECTIONS OF MORPHINE AS AN ADJUVANT IN THE REDUCTION OF INGUINAL HERNIAS.**—Dr. Philippe, of Saint-Mandé, recommends the use of hypodermic injections of morphine in recent cases of strangulated inguinal hernia, and reports three cases in which he administered them with excellent results. Taxis had been previously tried in vain, but after the injection of from one-third to one-half grain of morphine, it was resumed and proved entirely successful. One of the patients was an old man, ninety years of age, who was afflicted with a voluminous, irreducible inguinal hernia on the right side. During a paroxysm of coughing a fresh loop of intestine was forced into the sac. The injections of morphia, however, can only prove serviceable at an early period after the descent of the intestine; at a later period they are far less valuable than anesthetics, which not only relax spasm, but, if necessary, permit of an immediate resort to operation.—*Le Mouvement Médical*, May 26th.

**REMARKABLY SLOW PULSE.**—Dr. Trastour reports a case of algid pernicious fever, in which for several hours the pulse only beat ten times per minute. It was regular, but excessively feeble. Under the influence of large doses of quinine, stimulants, and revulsives to the extremities, it gradually became stronger and increased to 25 in the minute. For three days it varied between 20 and 28. The chill was not repeated, but an aggravation of a chronic bronchitis, from which the patient had been suffering, and a severe attack of diarrhoea set in, which proved fatal a few days later. Previous to death the pulse rose to 92, but fell again to 80. At the autopsy no trace of a heart-clot or of an embolism was found, and Dr. Trastour consequently attributes the sudden and intense disturbance of the cardiac rhythm to the influence of the malarial poisoning. The patient had been travelling on foot through a malarious district before his illness.—*Gazette Médicale de Paris*, May 26th.

**EXTIRPATION OF THE KIDNEY.**—Mr. Jessop, of the Leeds Infirmary, lately extirpated the left kidney of a child aged two years and three months, for malignant disease of that organ. The incision was similar to that recommended for colotomy, but longer. When the diseased mass was reached, the kidney was peeled by means of the fingers, and a whipcord was passed around the vessels and ureter and firmly tied. The remainder of the growth was afterwards stripped away and the whipcord left to drain the wound. The operation was a formidable one, owing to the large size of the diseased organ, and the free venous hemorrhage which followed the separation of the growth from the surrounding structures. When removed the kidney weighed sixteen ounces, and resembled encephaloid in appearance. At last accounts, five days after the operation, the patient was doing well.

## HOMEOPATHY.

WITHIN the past two months there has been some discussion in Great Britain concerning the merits and demerits of homœopathy, growing out of an offer, on the part of a distinguished follower of the doctrine, to join hands and interests with the regular profession. As this has been done before by parties who have been convinced of the error of their ways, the mere fact by itself has no great significance. But the peculiar circumstances under which the overtures were made, and the statements in connection with them, as well as the position of the person making them, have invited more than the usual attention. From the beginning it was a voluntary act on his part, with the best of motives, and with the avowed object of bringing about a reconciliation between the two schools of medicine.

The gentleman who took the initiative being Vice-President of the British Association of Homœopathy, his utterances were in the highest degree significant, if not almost committal on the part of his associates. But this is so far as the circumstances of the individual and the particular act in question are concerned. Behind all this there are matters of interest connected with the general subject which are brought prominently forward in the statements concerning the present status of homœopathy, and which give a reasonable promise at no distant day of a better understanding between the two parties.

The admission that homœopathy is not absolutely right; that errors have been committed by extremists; that the doctrine held by the founders of the system is markedly different from what it is to-day; and that it is not exclusive, is, we believe, a fair expression of the opinions of the majority of the Halmemannites of the present day. In fact, the very name is becoming obnoxious; and not only in Great Britain, but in this country, efforts have been made by societies to dispense with it altogether. Further than this,

it is proposed that a belief in the homœopathic creed shall not be insisted upon as a requisite for membership by candidates for admission into these organizations.

All this, we think, tends to prove that the exclusive dogma is a myth, and that true progress demands a greater expansion of ideas and a greater liberality of sentiment. It was, after all, this very exclusiveness on the part of the homœopaths which tempted the regulars to make martyrs of them and give them the opportunity of appealing to the public for sympathy and patronage. It was the latter course which caused them to be classed as designing quacks rather than innocent sufferers for mere opinion sake.

Nothing in a progressive science can be exclusive. The moment such a course is attempted there is an end to progress. It would be absurd to presume that the science of medicine is perfect, that the doctrines upon which it may now be founded are so far beyond question that there is no room for a difference of opinion and no toleration for unbelief. The contrary is the fact. The doctrine of homœopathy was not, as such, an offence to the profession, but its pretensions and absurd exclusiveness, its claim of absolute perfection and right, and its consequent intolerance of every contrary view.

Scientific medicine has the right and privilege of using any remedy and any means to benefit suffering humanity. The mere fact that a remedy is a so-called homœopathic one does not debar any one from using it. The regular profession do not believe in the doctrine of *similia similibus curantur*, but there is nothing to hinder it from employing very small doses, when ordinary experience and observation indicate that such a course is desirable. Any prescriber may have a theory to suit himself as regards the *modus operandi* of any given drug or sized dose, but he certainly has no right to assume that every one who does not hold the same view is necessarily a fool and a dangerous man. It was this absolutism that brought about a separation of the homœopaths from the regulars, while the gap was widened by the quackish endeavors of the former to appear to be what they were not. The fact that a practitioner believes in the doctrine of infinitesimals does not necessarily ostracize him, unless he refuses to believe in anything else. When the homœopaths are willing to acknowledge that there is another world than theirs, and are conscientiously inclined to study and practise medicine as a broad, progressive, and liberal science, there is no need to appeal for admittance to our ranks, for they are members already.

Scientific medicine is still what it always has been. It is not based on any single law, but is a simple accumulation of fact and experience bearing upon the treatment of disease. It must be necessarily liberal and progressive. As facts are the foundation of experience, it is with them we must deal, irrespective of the opinions upon which they may be apparently based. The physician who would not use a

remedy simply because it was employed by the homœopathist, would be as derelict of his duty to his patient as the homœopath himself, who, in his blind worship of his dogma, would not look beyond the pale of its influences to alleviate suffering or even to save life. The regular medicine of to-day is so perfectly untrammelled in its course that it appropriates everything which may be of service to the patient. Whatever is good of homœopathy, eclecticism, hydropathy, and every other "pathy" under the sun, legitimately belongs to us. If there be any significance in the present movement towards a proper understanding between the regulars and the homœopaths, it cannot be difficult for the latter to decide which is the mountain and which Mahomet.

#### HOSPITAL MANAGEMENT.

THE medical press of London, in connection with the scheme to establish home hospitals for the well-to-do, are discussing the prospective management of the same. While acknowledging the necessity of vesting the purely managerial functions into the hands of laymen, it is urged that all matters medical should be subject to a strictly professional board. This is as it should be; but why the medical element cannot have a representative upon the central board does not appear. The reason assigned, that professional jealousies would be thereby engendered, is frivolous, if not absurd.

## Reports of Societies.

### NEW YORK PATHOLOGICAL SOCIETY.

*Stated Meeting, May 23, 1877.*

DR. E. G. JANEWAY, PRESIDENT, IN THE CHAIR.

#### SUDDEN DEATH WITHOUT APPARENT CAUSE.

DR. MARY P. JACOBI exhibited the heart removed from a primipara, who died during an attack of dyspnoea, five hours after labor. Two hours before death she complained of precordial pain and dyspnoea. The latter increased until death occurred, the patient retaining consciousness to the last. The specimen was chiefly interesting on account of the negative character of the appearances which it presented, there being no explanation for the cause of death. Dr. Jacobi did not see the patient during life, and was not able to give any more of a history than that received from the friends.

At the autopsy the heart was healthy, and contained a clot of blood in the right ventricle, stretching forward into the pulmonary artery. There was also a clot in the left ventricle stretching across the mitral orifice. These clots were evidently post-mortem. The veins of the uterus, ovaries, and broad ligaments were carefully examined, but no thrombi were discovered. There were no coagula in the pulmonary artery, nor in any of the traceable branches of the vessel. In fact, the cause of death appeared to be mystery.

DR. JANEWAY remarked that it was always difficult to explain the cause of death in these cases when the idea of poisoning was left out of the question.

DR. JACOBI remarked that the patient had not taken anything which might lead to the suspicion of poisoning.

DR. ROBINSON believed that the clots were formed during the agony, as there were no impressions of the valves upon them.

#### PERSISTENT PLACENTITIS AND SUCCESSIVE PREMATURE DELIVERIES.

DR. CARO exhibited a degenerated placenta, discharged by a woman aged forty-two years, who had been delivered that morning of a still-born child in the eighth month. She was married at twenty-two years, and eighteen years ago she had her first child, who is still living. Since that time she has had, including the last, fourteen still-born children. These were born consecutively every year except during the last four, when an interval occurred. On nine of these occasions he attended the woman himself, and in each instance the child was born between the seventh and ninth months, and the placenta was fatty. Everything was done to counteract the tendency to the latter condition, but to no purpose. The family history was good, there being no hereditary taint discoverable.

DR. CARO mentioned a similar case of degeneration of the placenta, in which, during a period of ten years and after the first child, all the other four children in succession were still-born.

DR. BRIDGON believed that such cases had usually a syphilitic history. He mentioned a case in point, in which, although no history of the kind could be obtained, the anti-syphilitic treatment effected a cure.

#### CIRRHOSIS OF LIVER.

DR. C. HEITZMANN exhibited a microscopic specimen of cirrhosis of liver, in order to demonstrate certain facts which have been discovered in his laboratory by Dr. H. Chr. Müller—at present in Port Jervis, N. Y.—and published in the seventy-third volume of the Transactions of the Imp. Academy of Sciences in Vienna. Dr. Müller found that the epithelial elements of the liver, in a healthy condition, are separated from each other by a small shell of cement-substance, but united in their living part through delicate threads, traversing the cement-substance. In morbid conditions, especially that termed "interstitial hepatitis," the cement-substance of several neighboring epithelia is melted, and in this manner clusters of protoplasmic bodies, provided with a great number of nuclei, are formed. The living matter, which forms the nuclei, the granules, and the uniting threads, next increases in size, thus producing a coarse granular appearance to the clusters. Each granule may give rise to a new protoplasmic body, which, being in connection with all its neighbors, turns to a spindle-shaped body. A great many of such indifferent or juvenile elements are transformed into a finely granular basis substance, mostly without distinct striation. Epithelium, therefore, first goes back to a youthful condition, forms indifferent elements, the latter being the basis for the shrinking connective tissue. At the same time many blood vessels are transformed into connective tissue; hence, the latter is scantily provided with nourishing material. Many bile-capillaries fade away, while the remaining ones are dilated. This is, perhaps, the reason why the secretion of bile is interfered with in the highest degrees of the disease only.

#### REMOVAL OF VARICOSE VEINS.

DR. A. C. POST exhibited a specimen of varicose veins of the leg which he had removed by operation from a male patient of the Presbyterian Hospital, aged

45 years, who had suffered from the disease for the last twenty years. For four or five years he had an obstinate ulceration. The excision of the varicose tumor was removed under carbolic spray, and the communicating vessels were tied. At the end of forty-eight hours considerable febrile excitement occurred, the temperature rising to 104° F. Coincident with this was a strip of redness which extended along the course of the saphena vein from the knee to the groin, with pain on pressure. This alarming condition was, however, soon arrested by full doses of quinine and the local application of blisters. The veins in the specimen were very much thickened and indurated.

#### EXSECTION OF ELBOW.

Dr. A. C. Post also exhibited the bones of the elbow-joint, removed by operation from a girl aged 9 years, who had been greatly disfigured by a burn. The right upper extremity had become very much contracted, and the late Dr. Gurdon Buck had performed several operations to remedy that condition. In the last attempt Dr. Buck accidentally severed the brachial artery during the division of the cicatricial tissue. The limb was then placed in a straight position. In December the patient came under the care of Dr. Post, who, in attempting to bend the arm, fractured the olecranon process. There was at the time a large ulceration on the anterior aspect of the arm, nearly surrounding the limb. A compound fracture existing, the limb was kept in a straight position until union took place. At the end of several months, the ulceration still persisting, the only chance for a useful limb seemed to rest in excision of the elbow-joint, which operation was accordingly performed, the limb being placed at a right angle. Two months after the operation the limb is in good condition, the ulceration in the anterior aspect of the arm has entirely healed, and there is some motion to the joint. There is some moving power in the fingers also, which will doubtless improve by time and exercise.

#### EXSECTION OF CARPUS.

Dr. Post also presented the carious carpal bones removed by operation from a policeman, aged 35 years, who fourteen years ago strained his wrist by lifting a heavy weight. Inflammation, suppuration, and destruction of the parts followed, and from that time until he came under the care of Dr. Post, there was a more or less constant discharge from a number of sinuses communicating with dead bone. The operation was performed under the spray. For more than a week afterwards there was very little febrile action. On the ninth day after the operation, without any apparent cause, the temperature rose to 104° F. Under quinine this was reduced. On the tenth day he had a mild attack of erysipelas, but the local condition of the wound was everything that could be desired. About April 1st he complained of some swelling of the feet, and a large amount of albumen was found in the urine, together with oily and waxy casts. This condition of kidney came on quite suddenly, as previous examinations of the urine had resulted negatively. He failed rapidly after this, and soon after died. It was somewhat remarkable that, notwithstanding the grave condition of the general system, the local condition was so favorable.

#### A CASE OF CIRCUMSCRIBED EMPYEMA FOLLOWING FRACTURE OF RIBS—COMMUNICATION WITH BRONCHUS—RADICAL OPERATION—PERICARDITIS—PLEURITIS OF LEFT SIDE—DEATH—POST-MORTEM.

Dr. BEVERLEY ROBINSON presented a specimen of the above, with the following history: L. F., et. 54,

admitted to Charity Hospital, Jan. 30, 1877. Nine weeks previous, patient fell against table and fractured two ribs on right side. Prior to accident, patient in good health; ever since has had persistent cough and abundant expectoration. Physical examination reveals ordinary signs of empyema over median portion of right side of chest, posteriorly.

Further, in third intercostal space in front, superficial dry crepitus was noticed, and behind and under lower angle of scapula a tumor the size of a hen's egg, rounded, regular, and of solid consistence, was found; it was immovable under skin, which itself was healthy. Upon pressure it apparently disappeared into pleural cavity.

March 15th, irruption of empyemic contents into bronchus, followed by sudden much more profuse purulent expectoration; exploratory puncture evacuated small amount of pus from chest; radical operation was then performed over seat of tumor, but no more pus appeared, and wound was closed. When two days elapsed, discharge through wound, and evidently coming in great part from pleura. March 25th, signs of empyema were present below right clavicle, and a free incision was made in fourth intercostal space, below and outside right nipple; chest cavity was entered, but no liquid came from it. What was presumed to be middle lobe of right lung was felt. Posterior wound was now reopened, and soft catheter introduced into chest, and allowed to remain; anterior wound was closed. Within forty-eight hours pus came through catheter, and patient had greatly improved. Daily washings with detergent solutions were made, and discharge had notably diminished, when, April 8th, pericarditis, rapidly followed by pleuritis on left side, was developed, and patient succumbed, owing to sudden heart failure, April 21st.

Autopsy, made by Dr. E. A. Maxwell. Following condition of right side of chest was shown: *Pleura*, upper half prolonged to base posteriorly, is an immense cavity filled with decomposed pus; *costal pleura* at thickest point three-quarters of an inch thick, and so intimately adherent that house physician (Dr. Denslow) dissected it from chest wall; the cavity is lined by so-called pyogenic membrane, plentifully supplied by small blood-vessels; *pulmonary layer* forming inner layer of this cavity is one-eighth of an inch thick from fourth rib downward on anterior surface of lung; the two layers of pleura are united between the seventh and eighth ribs, about four inches anterior to the angle of rib. This empyema has perforated the thickened pleura, and opened discharges into the right posterior incision; the small point where it had perforated is irregular and three-quarters of an inch in diameter, and besides opening it, it communicates with a bronchus which can be traced to rest of lung; the mucous membrane of the latter is lined by exudations of croupous membrane; one inch behind and below this is another point where the empyema has perforated the pulmonary pleura. Corresponding to the first opening is an old fracture of eighth and ninth ribs. Underneath third intercostal space is a second circumscribed empyema of ovoid outline, two inches in longest diameter, running obliquely from third intercostal space downward and outward; the costal pleura is perforated, intercostal muscles disintegrated (this corresponds to the empyema noted on anterior wall of chest), and the pulmonary pleura over this space is destroyed by ulcerations. A direct communication with the bronchus can be traced at this point; corresponding borders of ribs are superficially necrosed for a distance of two inches.

Lung is pushed downward and inward, and is mark-

edly compressed; the prolongation of lower lobe causing moderate amount of fibrous induration; bronchi filled with thick muco-pus (tenacious); mucous membrane shows bronchitis.

Other organs had no special interest.

*Remarks.*—History of foregoing case appears interesting in several particulars: 1. Traumatic empyemas are relatively rare. 2. Circumscribed pleuritis of purulent nature are even more infrequent. 3. After reading detailed account of post-mortem, so excellently narrated by Dr. E. A. Maxwell, one can appreciate the difficulties I had during life to arrive at a certain diagnosis. Why did I not achieve anything more positive and satisfactory by my operations? The reply is evident: at the time I made the first incision there was little or no pus in the empyemic cavity. There was a communication through the much-thickened pleura, covering the compressed right lung, and extending from the limited pyogenic cavity to a bronchus, and it was by this road the purulent exudation had evidently been expectorated as fast as it was formed. Doubtless this exit was effected at the time purulent sputa became suddenly more profuse. After an opening into the chest was made, the pus formed within the empyemic cavity, took this route towards the exterior, rather than the one by which it passed before. When I believed I was in contact by my index-finger with the middle lobe of the right lung, I was touching a thick, though smooth false membrane, covering its entire under-surface.

I here desire to express my thanks to Drs. Rush and Denlow for efficient aid afforded me in the treatment of this very interesting case.

#### CARIES OF TARSUS—EXSECTION.

DR. ERSKINE MASON presented a patient upon whom he had performed exsection of the ankle-joint. The history of the case was as follows:

Mary Mulhoorn, N. Y., at 13. Admitted Roosevelt Hospital, October 10, 1876. Patient's family history good. Seven years ago, patient felt pain in right ankle. Does not remember having received any injury to part. It became very painful and swollen. Various methods of treatment were tried. After six months a number of openings formed spontaneously, discharging pus and blood, but no pieces of bone were noticed to come away. Two years later there was much improvement. Discharge from the ankle has continued ever since, and at intervals patient would suffer very severe pain.

On admission, find patient's right ankle swollen, slightly inflamed, and quite tender to the touch, but not severely painful. There are a number of sinuses opening on posterior part of ankle, from which flows a bloody serum. Dead bone is touched through these sinuses.

The affected limb is atrophied, and there is talipes equinus.

#### Measurements.

Circumference of right (diseased) leg just below knee.....	8	inches.
Circumference of left.....	8 $\frac{1}{2}$	"
" at calf right leg.....	7 $\frac{1}{2}$	"
" " left ".....	9 $\frac{1}{2}$	"
" just above right ankle....	6 $\frac{1}{2}$	"
" " left "....	6	"
" instep right foot.....	8 $\frac{1}{2}$	"
" " left ".....	7 $\frac{1}{2}$	"

*Treatment.*—Rest and wet antiseptic dressings applied to foot till February. Patient much improved; condition good. Ankle but slightly painful. Probe still touches dead bone.

*Feb. 10th, 2.30 P. M.*—Patient under ether. Resection of ankle-joint performed by Dr. Mason, assisted by house surgeon. Esmarch's bandage having been applied, a curved incision, about four inches in length, was made with scalpel, commencing about two inches above the lower extremity of fibula, extending downward and forward over the malleolus, and extending forward parallel with the sole of the foot about two inches (the tendons of the peronei muscles being drawn back out of the way). The periosteum was then separated from the lower end of the fibula, and its extremity, which was much diseased and softened, removed with bone-pliers. It was then discovered that the disease extended into the joint.

An incision was then made over the inner malleolus similar to the one on outer side of ankle, and the lower end of tibia reached. The tendon of tibialis anticus was carefully drawn to one side, and the extremity of tibia removed with bone-pliers, it being found to be carious and quite soft. Upon examination, it was found that the articular and upper surface of the astragalus was very much diseased, and that much of it had ulcerated away. It was very loosely attached, and was easily removed with necrosis forceps. The lower extremity of both tibia and fibula were then carefully scraped, removing all diseased bone. Esmarch's bandage was then removed. Hemorrhage was very slight, no ligature being used. The wound was irrigated with sol. acid, salicylic, and few silk sutures used. A drainage-tube was run through the ankle from side to side, through opening left near the centre of each incision. A plaster-of-Paris bandage splint was then applied, strengthened in front and behind by narrow strips of tin, bent in a loop over the toes and ankle, by which the limb could be readily suspended after the operation.

*Feb. 11th.*—Patient did nicely, and had very little pain. She gradually improved until April, when all supports were removed.

#### REPARATIVE PROCESSES IN POPLITEAL ANEURISM TREATED BY GENTLE FLEXION AND COMPRESSION.

DR. CHAS. K. BRIDGON presented a specimen of popliteal aneurism as a nucleus around which he had woven the history of the case of the late Prof. C. A. Budd. The thoracic aneurism which was the cause of death he had placed in the hands of Dr. Loomis; but as that gentleman was not present, he would, in connection with his own specimen, detail the autopsical appearances of the cavities of the chest and abdomen. Dr. Bridgdon then read the following history:

Prof. Chas. A. Budd consulted me, Sept. 24, 1871. He informed that for about a year he had some pain in the back of his right sciatic nerve; that a few months before, whilst crossing the Atlantic, he had wrenched his knee, and that on the morning of the day upon which he called at my office he had discovered a swelling in his right popliteal space.

At that time the Doctor stood six feet one inch in his stocking feet, and weighed one hundred and ninety pounds. He suffered occasionally from attacks of gout; otherwise enjoyed pretty fair health.

I found in his right popliteal space a pulsating tumor, centre of which was on a level with the apex of the patella. My estimate of its transverse diameter was two inches and a half; longitudinal, three inches. Pulsation was readily arrested by compression of the artery as it escapes the crural arch; continuance of such compression also caused entire collapse of tumor; lateral expansion was well marked, and the ear detected an unmistakable bruit.

I placed him upon iodide of potassium, in doses of

sixty grains a day, and used injections, into the immediate vicinity of the tumor, of ergotine. After a few days of this treatment the Doctor became impatient, and demanding something more active, on the 2d of October I commenced the treatment by genuflexion. This was used continuously night and day for two hundred and seventy hours, with the heel, in the beginning of the treatment, at a distance of eight inches from the nates; at a later period it was approximated to within five inches. The process was a very painful one, and required large doses of McMunn's elixir to make it all endurable. When the flexion had been used one hundred and five hours, evidences of consolidation first presented themselves, in the fact that the tumor no longer collapsed on compressing the artery above, and resembled in feel and size the half of a billiard-ball. After two hundred and sixteen hours I supplemented the flexion with intermittent digital pressure of the artery at the groin.

On the 13th I stopped the flexion, determining, after a few days' rest, to commence the use of compression.

On the evening of the 14th, Prof. Loomis, who had examined the case before the treatment was commenced, made a careful investigation, and stated that the tumor had diminished one-third, that a considerable degree of consolidation had taken place, and that the bruit had very considerably diminished.

Compression was begun on the 21st of October. The instrument used was one devised for the purpose at the time, and described in THE MEDICAL RECORD, April, 1872. Three points of pressure were used; one at the groin, one at three, and another at seven inches below Poupart's ligament. This compression was steadily maintained for fifty-six days, at an average of ten hours and a half a day, making five hundred and eighty-eight hours, complete in all its details. We were not annoyed by any of the accidents that are so frequently associated with compression, such as excoriations, or phlegmonous condition of connective tissue. For a larger portion of this time a just perceptible wave was permitted to pass through the tumor, but later on, when the great fortitude and endurance of the patient began to give out, I used the compression on several days, so that not a pulsation occurred, except when changing points of pressure.

After the first seven days direct compression was used at night by the adjustment of a pad of curled hair, but the indirect compression was used every day, save on one occasion, when some twinges of gout obliged us to desist.

For the last three weeks of this treatment no change occurred in the condition of the tumor. It was apparently diminished two-thirds, solid, without lateral expansion, but feeble pulsation, and scarcely perceptible bruit. Having now determined that there was either some local impediment or something in the plastic condition of the blood that prevented complete obliteration of sac and artery, it was deemed proper to permit the patient to get about. He soon resumed the active duties of his profession, and he never afterwards suffered from any increase in size in the aneurism.

The summer of 1873 was spent in London and Paris. He returned much invigorated, and at once resumed his duties of Professor in the University.

In the summer of 1874, whilst at the Delaware Water-Gap, he began to suffer from intercostal neuralgia, which proved to be of a most intractable character. On the 13th day of February, 1875, I first detected what I regarded to be the signs of aneurism of the thoracic aorta—an area of dulness between the posterior border of the scapula and the spinous processes of the upper dorsal vertebrae, and a bruit with

its maximum intensity on a level with the spine of the left scapula.

In 1875 the Professor again visited Europe. During his stay in London he was prostrated by suffering, and received the kind attention of Dr. Morel Mackenzie, who called Dr. Walsh in consultation. The latter gentleman expressed the opinion that he had a large aortic aneurism, that his condition was very critical, and advised his speedy return home.

In 1876 Prof. Budd resigned his position in the University, but continued to attend to his office practice. His sufferings from pressure on the intercostal nerves were of an intensely painful character, and relieved only by the abundant use of hypodermics of morphia. In the beginning of the present year he began to suffer from difficulty in swallowing, and for the three months preceding his death took little else than fluid nourishment.

In the early part of the afternoon of May 17th he began to complain of the old pain returning, and his wife, alarmed at the appearance of lividity which began to overspread his face, summoned assistance. I was absent, but Prof. Alf. Loomis and Dr. Walter Gillette were promptly at his bedside, and only in time to witness him breathe his last.

Prof. Loomis, his colleague in the University, had seen him often during his long illness, and I expected that he would have been present on this occasion to aid me in completing the history of the case.

Autopsy was made on the morning of the 18th, in the presence of Profs. Loomis, Arnold, and Dr. Bern Budd.

Left pleural cavity contained about thirty ounces of blood-clot, and about as much serum; the lung was bound to the chest-wall by firm and old adhesions; upper lobe in condition of fibrous induration; lower carnified, compressed; bronchi dilated.

Right lung emphysematous, and in condition of slight hypostatic congestion.

A large aneurism was found, filling more or less of the left chest, and bulging slightly into the right; its anterior wall was strengthened by a large hard coagulum of fibrine that weighed nearly two pounds; the bodies of five vertebrae were eroded, and the second and third dorsal were almost entirely absorbed.

Heart and valves were perfectly sound.

Liver—color normal; left lobe slightly diminished in size; right lobe normal; very slight appearance of waxy change.

Stomach distended; spleen healthy.

Kidneys—small, contracted; capsules slightly adherent; surface granular; section presenting appearance of chronic parenchymatous nephritis.

Right popliteal artery presents an aneurism about two and a half inches in both diameters; the sac is developed from the anterior wall, and communicates with the vessel by a long oval aperture; the cavity is almost entirely filled with a firm organized clot, the deep surface of which is furrowed by a channel that permits the transmission of blood to parts below; the posterior wall of the artery is marked by a large irregular patch of atheroma.

Dr. Briddon did not witness the symptoms immediately preceding his death, but Drs. Gillette and Loomis, who were present, supposed him to be suffering from collapse, the result of anemic poisoning. On opening the chest, the left pleural sac contained a clot of blood which weighed two pounds, together with a large amount of serum. The lung of that side was carnified, and everywhere adherent. Some of the bronchi were dilated, and there were minute changes in the lung structure, the nature of which he was

unable to determine. There was a large aneurismal sac, involving the thoracic aorta from its commencement at the termination of the arch down as far as the sixth dorsal vertebra. The larger portion of the sac was on the left side, but it encroached slightly on the right side. The bodies of the first five dorsal vertebrae were eroded, those of the second and third being almost entirely gone. The heart was perfectly sound. There were the remains of a pericarditis which dated back a considerable time. The liver was in some parts undergoing fatty degeneration. The kidneys were small and contracted; the capsules somewhat adhering, favoring the condition of parenchymatous nephritis. All the other viscera were sound.

The popliteal aneurism was developed from the anterior surface of the artery, the sac measuring two inches transversely, and two inches and a half in a longitudinal direction. The sac communicated with the aneurism by a more or less oval aperture nearly two inches in length. The sac itself was almost entirely filled with a firm clot, was furrowed into channels, through which blood had passed during life to the artery below the sac.

Adjourned.

### ARMY NEWS.

*Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from July 15 to July 21, 1877.*

SIMONS, J., Lieut.-Col. and Surgeon. Granted leave of absence for twenty days. S. O. 153, A. G. O., July 13, 1877.

SWIFT, E., Lt.-Col. and Asst. Medical Purveyor. Relieved from duty as Medical Director of this department to enable him to comply with S. O. 147, C. S., A. G. O. G. O. 6, Dept. of the Gulf, July 18, 1877.

ALDEN, C. H., Major and Surgeon. Telegraphic instructions of 30th ultimo to proceed from Fort Townsend to Lewiston, Idaho, and report at once to the Dept. Commander in the field, confirmed. S. O. 90, Dept. of the Columbia, July 6, 1877.

MATTHEWS, W., Capt. and Asst. Surgeon. To accompany Co. "D," 12th Infy., from Camp Independence, Cal., to Boise City, Idaho. S. O. 80, Div. of the Pacific and Dept. of California, July 5, 1877.

DICKSON, J. M., Capt. and Asst. Surgeon. Granted leave of absence for thirty days, on Surgeon's certificate of disability. S. O. 120, Dept. of the Gulf, July 13, 1877.

BRELL, J. W., First Lieut. and Asst. Surgeon. To accompany Cos. "D" and "L," 10th Cavy., ordered from Fort Concho to Fort Clark, for field duty. S. O. 127, Dept. of Texas, July 13, 1877.

GERMAN UNIVERSITY CALENDAR.—Through the kindness of Dr. Prout, of Brooklyn, we have received a copy of the second part of the *Deutscher Universitäts-Kalender* for the summer term of 1877. This little book, which is published twice a year, gives the names of the professors and tutors, and the subjects of their lectures, in all the German universities, including not only those in the German Empire, but also those in Switzerland and Austria, and that of Dorpat in Russia. The average cost of living in the more important university towns is mentioned. This calendar, of the existence of which most American students are ignorant, contains a great deal of information which would prove valuable to those intending to go abroad to study in the German universities. We have been surprised to learn from it that of the thirty-four universities, Berlin only stands seventh in the number of medical students. Vienna, of course, comes first, and Würzburg is second. The calendar is published by Leonhard Simion in Berlin, and costs about 40 cents gold.

CHANGES IN THE MEDICAL CORPS OF THE U. S. MARINE HOSPITAL SERVICE.—Dr. A. B. Bancroft, surgeon-in-charge of the Marine Hospital at Boston, Mass., has, after a full hearing, been removed, as recommended by the board of surgeons who lately investigated the management of said hospital. Surgeon Ralph N. Isham, who was in charge of the Marine Hospital at Chicago, has resigned. Assistant surgeon J. B. Hamilton has been promoted to be surgeon, *vice* Dr. Bancroft, removed, and assistant surgeon Truman W. Miller promoted surgeon, *vice* Dr. Ralph N. Isham, resigned. Doctor Francis H. Brown, of Massachusetts, has been appointed assistant surgeon, *vice* J. B. Hamilton, promoted; and Dr. John Godfrey, of Alabama, appointed, *vice* Dr. Truman W. Miller, to a like position. Those who passed highest before the Medical Examining Board, lately in session, were selected for appointment.

UNIVERSITY OF THE CITY OF NEW YORK, MEDICAL DEPARTMENT.—Prof. Jno. T. Darby, of the Medical Department of the University of New York, was elected, June 1st, to fill the vacancy in Bellevue Hospital, recently made by the death of Prof. Charles A. Budd. On July 1st, Prof. Darby was also elected visiting surgeon to the Mt. Sinai Hospital.

PROF. S. W. THAYER.—The honorary degree of LL.D. was recently conferred upon Prof. S. W. Thayer, of Burlington, Vermont, by the University of Vermont.

SMALL-POX AND DIPHThERIA IN PERSIA.—Small-pox and diphtheria prevail to an alarming extent in Persia.

ESMARCH'S BANDAGE IN AMPUTATION.—Esmarch's bandage is less useful in amputation than was anticipated, as the capillary hemorrhage, after the bandage is removed, is oftentimes stubborn and excessive. Hence, many surgeons, at the risk of being out of the fashion, are inclined to fall back upon the old plan with the ordinary tourniquet.

INGROWING TOE-NAIL.—Dr. C. G. Clarke, of Indiana (*Med. and Surg. Reporter*), in simple cases of ingrowing toe-nail, advises the scraping of a longitudinal line in the centre of the nail to transparent thinness. This enables the nail to bend and evert the edges. The latter could be much aided by the insertion of cotton under the angle. But this, after all, is an old and simple remedy.

## Original Communications.

### ON THE TREATMENT OF FRACTURES OF THE THIGH BY MEANS OF A MODIFICATION OF BUCK'S APPARATUS AND AN IMPROVED PLASTER BANDAGE.

By H. A. DUBOIS, M.D.,

SAN RAFAEL, CALIFORNIA.

FOR the last sixteen years I have used the method of extension introduced by Dr. Gurdon Buck, in quite a large number of cases of simple and compound fractures of the thigh, in civil and military practice, and generally with excellent results. There are, however, certain disadvantages—at least that has been my experience—in the method as now used. Among these I would mention the difficulty of accurate measurement from the anterior superior spinous process of the ilium to the malleoli, the latter being covered by the loop of thick plaster; the difficulty of supporting the foot at right angles to the leg by the ordinary foot-piece, it tending to sink down and thus to bring the strain of the weight obliquely to the axis of the leg, and therefore irregularly on the plaster on either side of the latter. Again, the plaster, as now applied, has its hold on the skin alone, and is apt to cause blistering of the surface, especially over the ankle. Frequently, on visiting a patient in the morning, I have found the weight on the floor, even when a perineal band has been used and the foot of the bed raised, due, of course, to the carelessness of the friends or attendant; but this fact makes it none the less difficult to avoid, in private practice at least. Still another objection that I would name is that the force reducing the fracture is applied almost entirely to the lower fragment, the perineal band being intended alone to keep the body from sinking down towards the foot of the bed. On raising this, the body, of course, acts as a counter-extending force, but, it seems to me, in an irregular manner. Lastly, there is no convenient mode of regulating, night and day, the extending and counter-extending forces. Some time ago, while treating a case of congenital club-foot in a child, in which both feet were extended so as to be nearly in a line with the axis of the leg, and both turned outwards, to avoid the clumsy and expensive modifications of Scarpa's shoe sold by instrument-makers, I made use of the method of extension introduced, I believe, first by Dr. Brainard, of Chicago, and afterwards, but independently, by Barwell, of London. It consists in applying a strip of adhesive plaster spread on cotton flannel to the leg lengthwise, laying a thin metal plate on it, and then in turning up the end of the plaster so as to cover the plate, and in applying a close-fitting bandage over all. At the upper third a wire loop is soldered to the plate; this is the *point d'appui* from which the extension is made, which, in cases of club-foot, is by rubber tubes; the attachment on the foot being by wire loops sewed to pieces of plaster shaped so as to apply themselves neatly to the part, and to allow the strain to come in a direction proper to rectify the deformity. In this case two plates and rubber tubes were of course required for each foot, to overcome the double defect. The extension was kept up night and day—in the night, through openings in the stockings, and in the day through holes in the shoes also—for some three months, with the result of a complete cure. What struck me most in this case was that I could put a strain of from five to eight pounds

steadily, for a week at a time, on the leg and foot of a child four years old, without causing the slightest irritation of the skin, or any uneasiness, and without disturbing the plasters, and that this could be continued from week to week, over the space of three months. If any one will try laying a piece of bandage lengthwise on the leg, placing a piece of tin on it, folding up the lower end, and applying a bandage around the whole, he will find that when he brings a steady strain to bear upon the lower third of the plate of tin, and parallel, or nearly so, to the leg, that the force will tend to press the plate towards the centre of the leg, its downward action being restrained by the loop of bandage, and the outward tendency of the upper two-thirds by the bandage. When plaster replaces the bandage, the strain will be divided between the overlying bandage, the skin, and the deeper-seated structures. I propose to apply this principle in the treatment of fractures. In order to prevent pressure on the malleoli, and at the same time to leave them uncovered, so that accurate measurements can be made, the loop of plaster, with the included tin plate on either side, should terminate two or more inches above the ankle. To allow the foot to be kept upright, and to prevent pressure on the ankle, I use a thin board the length of the foot, and twice its width; this I attach to the two pieces of tin, one on either side, by wire loops soldered to their lower thirds. (The strips of tin should be 2-3 inches wide, and long enough to reach from a point two inches above the ankle up to the knee-joints. Holes should be made through the overlapping plaster for the wire loops.) This attachment is made with rubber tubing three-eighths of an inch in diameter. The tube on either side should pass through the loop on the tin plate, and its ends should then go through openings in the foot-piece and be wired together.

The lower holes should be about two inches below the axis of the leg, and the upper about the same distance above it, and both near the side of the foot-piece. The tubes, having been thus arranged, are now fastened together by a loop of strong wire. It will be seen that while the foot-piece is movable, and can thus be secured to the foot, the tubes on either side are at their base four inches apart, leaving ample space for the malleoli, and thus avoiding all pressure on the ankle, and allowing of the most accurate measurements, without which it is impossible to treat fractures of the thigh intelligently. In order to make extension I prefer a small spring-balance, though the weight and pulley can be used if desired, but I believe the former in general safer and more convenient. These balances may be had in the stores, about four inches in length, graduated up to twenty-four pounds, and for about fifty cents each. This is secured to the foot of the bed by a hook, or tied by a wire, while the rubber tubes are secured to its other end directly, or, if greater play is desired, by means of a piece of tubing. The counter-extending force consists of a second spring balance secured to the head of the bed, and attached by its lower end to a piece of tubing a foot or more long, which is connected with the perineal tube by a cord. This should consist of a five-eighths inch tube, which should be filled with water, and the ends tied. It should pass around the thigh, and its ends be secured together a little above the hip, and then connected with the balance by means of the cord above mentioned. If a more perfect pull is desired on the whole of the pelvis, as may sometimes be wished, as in intercapsular fractures and those close to the joint, a longer tube, filled as above, is loosely passed around the hips, and then secured together in

either groin. In this case it should be connected by a cord on either side, and two tubes should also be used to attach it to the counter-extending force, which preferably should also be double. In using this apparatus the bed should be level, and the counter extending balance should indicate at least a pull of one-half of that of the extending balance. These should be firmly attached to the bedstead, while the strain may be increased or diminished by means of the cords connecting the tubes to the balances. The perineal tube, when filled with water, I have found readily borne, even when the strain is considerable. By this modification of an old and well-established method of extension, I think some of the objections that I have mentioned will be done away with, while the trouble and expense are little, if any, more.

The patient can sit up in bed and enjoys a good degree of freedom of motion, owing to the elasticity and length of the rubber tubes, while the spring-balances keep a perfectly even pull, and allow the physician to see exactly the amount of the extending and counter-extending force at any time. I usually apply a plaster-of-Paris bandage by the end of the second week, or so soon as the bones are fairly knit. The only peculiarity about this bandage being in a device for keeping up counter-extension by means of a perineal tube. The plaster bandage is applied as usual, the body being supported on a thick pillow, and the limb by the hands of an assistant, both under extension.

On the outside of the thigh, and extending up an inch or so above the crest of the ilium, and down well on the thigh, a piece of flannel dipped in the plaster is applied, and layers of the bandage over this. A piece of thick tin plate, three inches wide, and long enough to reach, when folded on itself, from the middle of the thigh to three or four inches above the hip, is folded over the perineal tube in such a way as to leave an opening through which the tube can afterwards be passed. Between the folds of the tin a piece of flannel should be secured by stitching. The flannel is now dipped in the plaster and applied on the outside of the thigh, and the plaster bandage over it with a few turns of the roller over all. When the parts are dry, the plaster casing around the hip should be trimmed, and the perineal tube filled with water, secured by passing it through the opening between the folds of tin, and tied at any degree of tension required. I have now a patient out walking on the 27th day after an oblique fracture of the middle third, with only a slight plaster casing over the front of the thigh, and though I have made repeated measurements I can find no perceptible shortening—certainly there is not more than one-sixteenth of an inch, if that, though early in the case I could readily get one and a half inches by relaxing the extension. I would add that as soon as I conceive it safe the plaster bandage is removed by cutting it off from the inside, and the portion covering the thigh only is replaced, and secured by bandages, while the counter-extending force is kept up. With this apparatus I am able to get my patients safely on their legs at a very early period. Doses of ten grains of the lacto-phosphate of lime, three times a day, have also aided. I think, in shortening the time of confinement in bed, by giving rise to an early union. The points that I desire to call attention to, in the above paper, in an especial manner, are as follows: 1st. The use of a measured extending and counter-extending force, with a level bed. 2dly. The mode of applying the plaster to the leg, thereby avoiding irritation, distributing the strain over the skin, deeper-seated parts, and over-

lying bandage, and enabling the surgeon at all times to make accurate measurements. 3dly. The use of a movable foot-piece, connected by elastic tubes to the leg, and which can be firmly fastened to the foot by adhesive plaster, thus always insuring that the latter shall be at right angles to the leg, and the strain thus be brought on the plaster in a direct line, while the malleoli are left uncovered. 4thly. The perineal tube, filled with water, I claim, distributes the pressure more equally than any other counter-extending apparatus in use. Lastly, by the judicious use of the plaster-of-Paris extension, I think a majority of cases can be allowed to take exercise freely with nothing more than a slight plaster casing on the thigh alone, connected with the perineal tube, and worn only during the day, by the end of the fourth week.

In conclusion, I add that I usually find no bandage on the thigh necessary, but for the first three or four days apply a cold-water dressing if there is much swelling, afterwards in rare cases coaptation splints; that I measure the thigh the first week at least once in forty-eight hours, but during the second week every twelve hours, until the bones are firmly knit and the plaster applied. I find a thin hair or a woven wire mattress, placed on a three-quarter iron bedstead, the most convenient for treating all fractures of the lower extremities. The use of the spring-balances instead of the weights and pulleys I consider a matter of convenience only.

In the above article I have made no mention of the yielding of the ligaments of the injured thigh under the force employed in the reduction of the fracture. That the joints do yield in a sound limb I think there can be no doubt of, when a weight of from fifteen to twenty pounds is employed. Doctor Dalton claims that this amounts to half an inch (see *Trans. Med. Soc. of Cal.*, 1874, page 97). But the question is, how much do they give in a fractured limb? He recommends making extension for two hours on both limbs before measuring. It seems to me that a very useful table could be constructed by ascertaining the lengthening of sound limbs under weights. The time of extension, the weight employed, and the weight and age of the patient should be given. By its aid the surgeon would be able to make a proper allowance for the yielding of the ligaments in the fractured limb, and thus obtain cures with less shortening, though I cannot agree with the physician already cited that shortening can thus in all cases be entirely prevented. Captain Allen, an old sea-captain, has invented (see *Trans.*, above cited) a measure something like the shoemaker's rule, which goes over the patient and measures from the crown to the anterior superior spinous processes (by a cross-piece), and extending down between the feet, admits a very accurate measurement by a sort of square applied to the malleoli, while the length is read off on the longitudinal bar. This could, doubtless, be used in hospitals to good advantage, but is not adapted to private practice. If the three measurements—from the superior spinous processes to the malleoli, to the patella, and from the umbilicus to the malleoli in the fractured limb—are slightly greater than in the sound limb, I think we will not be far wrong, and if we apply to these the correction which the table above suggested would enable us to do, *i. e.*, the difference in the yielding of the ligaments between the fractured and sound limb we should approach absolute accuracy.

MORTALITY RATE.—Munich has at present the highest mortality rate, being 42 per 1,000.

## NITRITE OF AMYL IN TINNITUS AU-RIUM.

By SWAN M. BURNETT, M.D.,

WASHINGTON, D. C.

ANY means that offers a hope of relieving tinnitus aurium is deserving of consideration, for it is not only the most annoying symptom of aural disease, but the one that, as a rule, is furthest removed from the influence of our remedial measures. It is true that, in cases of recent catarrh of the middle ear (including the Eustachian tube), we can, in a number of instances, mitigate the severity of the symptom by the judicious use of Politzer's bag and the catheter; but in those cases where the catarrh has become chronic, and particularly if it has assumed the form known as hypertrophic, inflation of the middle ear is seldom followed by marked relief, and even puncture of the membrana tympani, which has of late years been recommended for this form of catarrh, is only occasionally successful.

In those cases where the pathological changes are confined to the nervous apparatus—perceptive or conducting—there is nothing that we can turn to with any assurance of benefit. A remedy adapted to this form of aural disease is a *desideratum*.

Narcotics have been the remedies generally experimented with, and a number have been tried by Tröltsch, Moos, and others, but with no definite result. They have been used internally, and externally by pouring them into the external ear. Electricity, too, for which some hope was raised in the therapeutics of the ear, has failed to give us anything that can be depended on, though there are some instances, one or two of which have fallen under my own observation, where the noises have been notably diminished under its use.

Recently, however, another narcotic has been proposed and tried, which has been found so far useful as to demand a more extended trial, and that is the nitrite of amyl by inhalation. In the last number of the *Archives of Ophthalmology and Otology* (Vol. V., Nos. 3 and 4) Dr. Michael, of Hamburg, reports the results of its use in twenty-seven cases of his own, and six in the practice of Dr. Urbantschitsch. Summarily, these results are as follows: greater or less improvement in nineteen cases, as regards the tinnitus, in one or both ears. In five cases the hearing power was considerably improved. The greater part of the cases was of that class known as otitis media hypertrophica; three only were of labyrinthine disease, of which one was improved.

More recently, Wöber-Liel, in the *Monatsschrift für Ohrenheilkunde* (March, 1877), has reported some experiments with the agent, in which two cases were benefited. In one the hearing power was improved, but he tinnitus was not; in the other the noises were diminished, but the hearing power remained the same. They were both cases in which there were changes in the middle ear. He gives to Michael the credit of being the first to study the effect of the agent in ear troubles.

A case has recently presented itself in our practice which seemed particularly fitted for a trial of the remedy in respect to its influence on tinnitus. The following is its history in brief:

Mr. B., twenty-nine years of age, had an attack, thirteen years ago, of what his physicians called brain fever." He vomited exceedingly hard at the commencement of the attack, and even before he lost consciousness was unable to hear anything spoken to him "on account of the great noises in the ears."

After recovery the noises continued, but his hearing power was completely lost. In that condition he came to me on the 17th of April of this year.

An examination showed the absence of any cause for the trouble in either the external or middle ear; the deafness is purely "nervous."

The noises are at times exceedingly troublesome to him, and especially so when he is irritated or worried. He continually translates them into conversations or speeches, or even songs which he had heard before the loss of hearing power. When parties are conversing near him the noises invariably assume the form of the conversation he imagines them to be carrying on.

I gave him, on the 17th, an inhalation of 2 drops of the nitrite of amyl. It was accompanied by the usual symptoms attendant upon its inhalation—flushing of the face, quickened and somewhat irregular pulse, slight injection of the conjunctiva, and dizziness. On the supervention of these symptoms the noises ceased entirely; not a murmur was to be heard. They remained absent for about two hours, when they gradually returned, but not to their former intensity.

On the 19th another inhalation was given. It was repeated on every alternate day until the 1st of May, with a like result. They were then suspended for six days to try the effect, but the noises did not return to their previous intensity, and the inhalations were again begun and continued as before, on alternate days, until the 25th, with no change in the effect of the medicine, except that the duration of the freedom from noise was shortened to about 1½ hours.

The patient, a man of fine intelligence and a close observer, is confident that the noises are very materially diminished. He can no longer get up his imaginary conversations, which had previously been such a source of annoyance to him.

An effect of the inhalation of this agent, that I have not seen noted, was observed in this case, and is worthy of mention. At every inhalation, at the period of flushing of the face, he notices a round bright yellow spot in front of the eyes, which, projected on a white paper at a distance of 30 centimetres from the eye, has a diameter of 3 cm. As the circulatory excitement subsides, this gradually fades out.

This phenomenon, it seems to me, can have only one cause for its production. There must be an overfilling of the vessels in the interior of the eye, resulting from the general disturbance of the vaso-motor system from the action of the narcotic. This overfilling in the vessels of the choroid makes pressure on, and causes an irritation of, the layer of rods and cones in the region of the macula. I say in the region of the macula, because the scotoma was in the line of direct vision. From the known formula

$$b = \frac{B \cdot g'}{g},$$

we can calculate the size of the region of the retina affected. In this formula  $b$  = the size of this region,  $B$  = the size of the image as projected on the paper = 30 mm.  $g'$  the distance of this projected image from the eye = 30 centimetres or 300 mm.  $g$  = the distance of the retina from the second nodal point of the eye = 15 mm. Substituting, therefore, we have:

$$b = \frac{30 \times 15}{300} = 1.5 \text{ mm.},$$

or about the size of the optic disc. We judge this vascular pressure to proceed from the choroid, because the blood-supply of the retina at the macula consists of capillaries which, on account of their fineness, could hardly make the pressure requisite to call forth the scotoma.

We have tried the nitrite in another case of im-

paired hearing from nerve affection, which, however, was unaccompanied by tinnitus. In this instance no beneficial action was noted.

The employment of the remedy is purely empirical; we can explain its action only on the ground of its influence on the sympathetic system, and in what manner this action can exert a beneficial effect on the auditory nerve must, in the present state of our knowledge, remain a matter of conjecture. The benefits that have appeared to follow its use, however, justify its further trial, and it is only by an accumulation of cases in which the remedy has been tried that we can arrive at a just knowledge of its value. After we have fully demonstrated its usefulness we can indulge in speculations as regards its *modus operandi*.

1101 F St., June 1, 1877.

## A FEW WORDS ON THE PURPLE OF THE RETINA.

By ADOLF ALT, M.D.,

OF TORONTO, CANADA.

LATE RESIDENT AND ASSISTANT SURGEON TO THE NEW YORK OPHTHALMIC AND AURAL INSTITUTE.

ALTHOUGH the important discovery of the purple coloration of the retina during life by *Boll*, and the subsequent experiments of *Kühne* and others during the past few months, have afforded much food for discussion in European medical literature, as yet little seems to have been done in regard to this subject among American scientific men.

After having made some experiments myself, I took occasion to demonstrate the fact before my class of histology of the eye, when lecturing on the normal histology of the retina (on the 5th of May). This demonstration, perhaps, may present some points of general interest. It was done in the presence of Drs. H. Knapp, E. Grüning, and T. R. Pooley.

A small dog, which had been kept in a dark closet for six hours, was killed, and one of his eyes enucleated by the illumination of a small gas flame. I then removed the anterior portion of the eyeball and the vitreous, and everted the posterior part upon my finger. As long as the retina was smoothly applied to the underlying choroid hardly any color could be perceived. As soon, however, as it was drawn up into folds, these showed a faint but unmistakable roseate color. I then exposed the specimen to daylight, and in about one-quarter of a minute the color was transformed into yellow, which remained the same when the specimen was brought back into the dark room.

The other eye showed the same conditions.

The purple was seen also in that part of the retina which lay upon the tapetum.

Since *Kühne* had advanced the idea that the pigmented epithelial layer was the one to produce the purple, I made some more experiments on albino rabbits. They gave the same results as to the existence of the purple.

Leuckart (*Graefe and Saemisch*, II., 2, p. 217) states that the tapetum is covered with an epithelial layer similar to the surrounding pigmented epithelium, yet without containing pigment. In albino rabbits again we find a layer of unpigmented epithelial cells separating the choroid from the retina.

These experiments would thus clearly demonstrate that it is at least not the pigment of the epithelial layer between choroid and retina which produces the purple.

N. B.—In an article (printed in the *Verhandlungen des naturhistorisch-medizinischen Vereins zu Heidelberg*, Carl Winter, 1877), "Zur Photochemie der

Netzhaut, von W. Kuehne," page 484, Prof. Kuehne draws from the same facts named in the foregoing paper the same conclusion, that the pigment of the epithelial layer cannot be the agent by which the purple of the retina is formed.

## Progress of Medical Science.

A NEW METHOD OF DETECTING A SIMULATED MONOCULAR AMAUROSIS.—Although we already possess numerous means for determining the existence of monocular amaurosis, the following new and simple diagnostic point, which has been recently pointed out by M. Galezowski, is both interesting and valuable. When the patient is turned towards a strong light, and the healthy eye is closed completely, the pupil of the amaurotic eye dilates. When the light first strikes the healthy eye the pupil contracts, and the pupil of the amaurotic eye contracts sympathetically; but when the healthy eye is closed the pupillary sphincter of the diseased eye relaxes. As a rule, this dilatation of the pupil can be readily seen with the naked eye; the simultaneous and equal contraction of the two pupils is seen to be succeeded by a slow and progressive dilatation of the pupil of the diseased eye, as soon as the healthy eye is closed. The pupil, as a rule, attains a diameter of four and one-half to five millimetres, but in some cases the dilatation is less marked, and can only be distinctly seen by the aid of a lens. It is impossible for malingerers to simulate this sign.—*Gazette Medicale de Paris*, May 26th.

METHOD OF ARRESTING HEMORRHAGE AFTER EXCISION OF THE TONSILS.—In removing the tonsils with the guillotine it is important to remember that the organs are situated obliquely, like the pillars of the soft palate; more pressure should be made upon the lower than on the upper border of the instrument, and the tonsil will then be readily seized. It is better not to attempt to remove the whole of the organ, for after the removal of a portion the rest will atrophy, and removal of the whole is liable to be followed by dangerous and very obstinate hemorrhage. The hemorrhage may be due to the existence of inflammation at the time of operating, which inflammation also has a tendency to make the substance of the organ friable, so that it will have to be removed in small pieces; hence it is always advisable to defer the operation until the inflammatory stage has passed.

The great danger of hemorrhage, however, lies in the possibility of opening into the rich venous plexus which lies at the bottom of the tonsillar fossa, and which is very easily wounded when the tonsil is removed entire. The hemorrhage from this source is sometimes extremely profuse, and is kept up by the movements of deglutition and spitting. The bleeding is not always primary, hence it is necessary to keep the patients under observation for a time. Sometimes it recurs after it has been once arrested. All the usual methods of checking the bleeding are unreliable, with the exception of direct compression made by the finger of the surgeon. The finger should be introduced into the mouth and applied directly to the wound, while counter-pressure is made from in front. This position must be maintained for several minutes notwithstanding the attacks of suffocation, the effort at vomiting, and the cough which the method excites. The hemorrhage is generally arrested at the end of two minutes. Dr. Panas, of the Hôpital Lariboisière in Paris, has on three occasions been called on to stop considerable hemorrhages from this cause, an

succeeded in promptly arresting them by this procedure.—*Journal de Méd. et de Chir.*, June, 1877.

**THE EMPLOYMENT OF CATGUT TO STOP BLEEDING FROM BONES.**—Dr. Riedinger, in a paper with the above title, calls attention to the difficulty that is often experienced in checking hemorrhage from the nutrient vessels of the bones after amputations and resections. Cauterization does not always succeed, and the introduction of small tampons of wax is contrary to the principle of antiseptic dressings. He recommends, as a substitute, the introduction of one or more bits of catgut into the vascular canal until it is completely obliterated. This is a method which he has himself employed with success, the hemorrhage being arrested at once. One great advantage of the catgut is that it is completely absorbed from the midst of the tissues, and does not interfere in the least with union by first intention. This has been proved by experiments made on dogs. (See RECORD, No. 300.)—*Centrablatt für Chirurgie*, No. 16.

**ANOTHER CASE OF POISONING BY THE SO-CALLED "HOMŒOPATHIC SOLUTION OF CAMPHOR."**—Mr. Philip Grubb, of Warminster, England, reports the following case: A young gentleman aged eighteen years, reading for Oxford, of fair average health, in whose family no trace of hereditary tendency to epilepsy exists, took for the cure of a cold seven doses of homœopathic camphor between 6.30 A.M. and 12 noon, on April 11th. Each dose, he says, was three drops, but probably he took more than three drops each time. Within five minutes after taking the last dose, without the slightest warning, he had a severe epileptic fit, in which his tongue was badly bitten. Mr. Grubb did not see him during the convulsion, but the description given of it was such as to leave no doubt of its nature. It lasted more than fifteen minutes. After the fit, the patient felt, as he said, "queer," and complained of a peculiar cold sensation on the tongue, extending for about half an inch from the tip. After the immediate effect of the attack passed off, he was put on bromide of potassium, which, however, did not seem to agree with him. He was then ordered nux vomica, liquor potassæ, and infusion of cusparia. On May 7th he was all but well, though not quite what he was before the attack occurred.

The two labels on the bottle of camphor were as follows:

"Saturated Spirit of Camphor, as used by Dr. Rubini. Ten times the strength of the ordinary Spirit of Camphor."

"Concentrated Solution of Camphor. Dose, two or three drops on sugar, every fifteen minutes; less frequently when relieved."—*The British Medical Journal*, May 19th.

**ON THE EXCRETION OF INDICAN AND OF LIME IN DISEASE.**—Prof. H. Senator, of Berlin, in the course of his investigations on the quantity of indican excreted with the urine in various diseases, was struck with the fact that urine which contained an abnormally high percentage of indican was very frequently, but by no means always, remarkably rich in lime salts. In cases of pulmonary phthisis, for instance, an abnormally large quantity of lime is excreted with the urine, even when but small quantities of food are taken, and in spite of the existence of diarrhœa, and it is in this disease especially that the coexistence of large excretions of lime and indican is most easily demonstrated.

A similar coincidence is very frequently met with in children, in whom, as Dr. Senator has shown, the excretion of indican is very often abnormally large.

Next to rachitis he thinks that glandular swellings are most frequently attended by increased excretion of lime salts.

In acute febrile diseases (pneumonia, typhus), the indican and lime salts do not increase *pari passu*, but rather the opposite. The difference is probably in part due to the influence of the diminished supply of food on the lime salts. Pleuritis exsudativa is the only one of these affections in which, notwithstanding the existence of fever, he has noticed an increase in the quantity of lime excreted.—*Centrablatt für Med. Wissenschaften*, June 2d.

**TRANSFUSION SUCCESSFULLY PERFORMED IN A CHILD.**—At the stated meeting of the *Philadelphia Obstetrical Society* on February 1, Dr. A. H. Smith presented for Dr. Stokes, of Moorestown, N. J., the history of a case of transfusion in a boy nine years of age. The patient was suffering from an attack of typhoid fever, which ran the ordinary course until the middle of the third week. He then began to bleed freely from the nose and gums and to pass blood with his urine. The flow from the nose and gums was stopped by Monsel's solution, but would break out afresh on the slightest provocation. Every passage of urine contained, as nearly as could be judged, from two to five ounces of blood. Numerous petechial spots, varying in size from a silver dime to a half dollar, appeared on the skin. Despite the use of iron, alum, and gallic acid, the hemorrhage continued unabatedly for seven days, when transfusion was determined on. Two and one-half ounces of the father's blood were injected into the median vein of the right arm. The oozing from the nose and gums stopped almost immediately after the operation, and urine passed half an hour afterwards contained neither blood nor albumen. On the second day after the operation the patient was exceedingly prostrated, and there was some bleeding from the nose, which, however, was readily checked by a spray of equal parts of Monsel's solution and water. The improvement was subsequently rapid, and in three weeks the patient was able to go down stairs.

The influence of the operation on the hemorrhages in this case cannot be denied. It is an important point, however, that the urine which was passed half an hour after the operation, and which contained neither blood nor albumen, had been collecting in the bladder for two hours before the operation. The fact that the blood transfused was defibrinated, is of interest in view of the opinion of Lesser (*Boston Medical Journal*, June 26, 1876), that the transfusion of defibrinated blood has no influence in arresting transudation from bleeding surfaces, but is only useful in restoring the nutritive fluid when the drain has been stopped.—*American Journal of Obstetrics*, April, 1877.

**GASTROTOMY SUCCESSFULLY PERFORMED IN A CASE OF RUPTURE OF THE UTERUS.**—Dr. Hart, of Nieuwer Amstel, in Holland, relates a case of spontaneous rupture of the uterus, in which the patient's life was saved by gastrotomy. She was 37 years old, and was the subject of pelvic contraction. Of three previous labors, the first had been completed naturally after lasting three days; in the second and third the fœtus was extracted with difficulty by forceps. The fourth labor had advanced so far that a segment of the head was engaged in the pelvis, and Dr. Hart was about to use the forceps, when suddenly, while an examination was being made, violent uterine action took place, and considerable hemorrhage occurred from the vagina, after which all pains completely ceased. The fœtus gradually receded, and, after a few minutes,

was out of reach, slight sanguineous discharge continuing. The pulse rose to 100, but remained full.

Nine hours after the rupture took place, gastrostomy was performed, Dr. Hart having been obliged to defer the operation in order to perform craniotomy in another case. The pulse had then risen to 126, and there was severe abdominal pain. The fetus and placenta were found entirely within the peritoneal cavity, the former lying in a dorso-anterior position. The uterus was firmly contracted. In the supra-vaginal portion of the cervix, anteriorly, there was a transverse rent, 3 cm. in length. As no bleeding was taking place, and there was not sufficient room between the rent in the uterus and the bladder, no sutures were employed, but the pelvis was carefully sponged out. Convalescence was uninterrupted, the temperature never rising above 38° C. (100.3° F.), and the patient was able to go out of doors thirty-three days after the operation.

Dr. Hart contrasts the success of this case with the results in a series of thirteen cases collected by Prof. Lehman. In none of these was gastrostomy performed, but in most the fetus was extracted by version or the forceps. All the patients died within a few days.—*Nederlandsch Tijdschrift voor Geneeskunde*, 1876, No. 42, and *The Obstetrical Journal of Great Britain and Ireland*, June, 1877.

A SIMPLE MEANS OF SECURING THE BEST POSTURE FOR THE LEG IN A CASE OF COMPOUND FRACTURE.—Dr. Banga, of Chicago, has invented a very simple method of securing a fractured leg in a good position. His apparatus consists simply of a smooth board, eight to ten inches wide and long enough to extend from the heel to the popliteal space, and some oblong blocks of wood. The leg having been put up in plaster-of-Paris, as soon as this has hardened, is raised over the board and secured in position at the proper height (from six to eight inches) by two piles of blocks, one beneath the ankle and the other beneath the popliteal region. Three turns of a plaster bandage are taken around the leg above the ankle, and the bandage next carried three times around both leg and board. Another roller is then wound tightly around the parts of the bandage which extend from the leg to the edge of the board, so as to roll it up into round, slender cords, which are finally coated with plaster cream. A bandage is then similarly applied below the knee. When these have hardened completely, the block pillars are taken away, and the limb remains supported on the four slender pillars or stilts.

The advantages claimed for this apparatus are: that it is easy of application, and the material can always be easily obtained; that it renders the dressing of the wound easy for the surgeon and painless for the patient. All parts of the leg can be got at without difficulty, and dressings applied without moving the limb at all. The stilts, though apparently slight, are very strong, and large portions of the bandage can, when necessary, be cut away, without interfering with its usefulness. When desired, extra stilts can be made without difficulty.—*Chicago Medical Journal and Examiner*, June, 1877.

ON A NEW FUNCTION OF THE LIVER.—In a series of experiments, most of which were made in connection with Prof. Schuff, of Geneva, Dr. Lautenbach has tied the vena porta of mammals nearly sixty times, and always obtained the same symptoms, viz.: a great tendency to sleep, due to the abolition of both tactile and general sensibility; slow pulse and increased followed by decreased arterial pressure; paresis of the heart-arresting fibres of the pneumogastries; slow and fre-

quently stertorous respiration; death, without convulsions, in from half an hour to four hours. Ligation of the hepatic veins produced absolutely no symptoms. Dr. Lautenbach believes that the above symptoms were due to the accumulation in the blood of a poison, which, under normal circumstances, is destroyed in the liver. In thirty-four experiments, from one and a half to three cubic centimeters of venous blood, taken from dogs dying from ligation of the vena porta, were injected into the lymph-sacs of the thighs of frogs, and these animals always exhibited symptoms analogous to those following ligation of the vena porta in the higher animals, and almost always died within three hours. The injection of venous blood taken before the ligation never caused these symptoms. It follows from these experiments that the blood of the animal contains a poison, which does not exist to an appreciable extent in the blood under normal circumstances, but accumulates as soon as the vena porta is tied. It was impossible to isolate this poison, on account of its great volatility or destructibility; heating the blood but slightly in a water-bath was frequently sufficient to cause it to lose its poisonous properties.

Now, one drop of nicotine injected into the general circulation will kill even a large dog. Dr. Lautenbach found that in the normal dog the injection of one-half a drop never causes death, but that after the vena porta has been tied, the injection of even one-fifth of a drop is usually rapidly fatal. On the other hand, even two drops of nicotine failed to kill a normal dog, when injected into the intestine or into one of the veins of the portal circulation. One-fifth of a drop injected into the intestine of a frog produced slight symptoms of loss of sensibility, but one-fifth of a drop injected after the extirpation of the liver proved rapidly fatal. He claims that these experiments prove that the poison is destroyed in, or by the instrumentality of the liver. The nicotine lost its extremely poisonous qualities when kept for a time in contact with liver substance that had been removed from the body, but contact with kidney substance had no effect on it.

*Hyoseyamina*, also, loses its poisonous properties while passing through the liver, or when the liver is macerated with it out of the body. When, however, the kidney or spleen was macerated with hyoseyamina, this poison did not lose any of its virulence. The symptoms caused by hyoseyamina and by the ligation of the vena porta in mammals present a remarkable similarity. *Conia* is another drug the active properties of which are destroyed by the liver. This organ also destroys the active properties of the venom of the cobra snake. Curare, prussic acid, and atropia, on the other hand, are not affected by it.

Extirpation of the liver in frogs produces at first no apparent symptoms, but still it leads to the development of a poison. A few days afterwards, whenever they are placed or rubbed on the back, they croak even more constantly than a frog whose cerebrum has been removed. The same symptom is noticed in frogs poisoned by hyoseyamina. In both instances the symptom is probably due to the influence of the poisons on the brain, to a paralysis of the arresting influence which the cerebrum exerts on the reflex action of the voice.

Dr. Lautenbach closes his paper with the following conclusions, which he believes to be strictly deducible from his experiments:

1. The liver has for one of its functions the office of destroying certain of the organic poisons.
2. A poison is being constantly formed in the system of every animal, which it is the office of the liver to destroy.—*Philadelphia Medical Times*, May 26th.

## Reports of Hospitals.

### BELLEVUE HOSPITAL.

#### REPORTS OF PRACTICE AND PECULIARITIES OF TREATMENT.

##### LEUCORRHOEA OCCURRING IN A GIRL AGED EIGHT YEARS —ASCARIDES ELIMINATED AS A CAUSE.

THESE cases are sometimes very annoying, and an item may not be amiss. The girl had suffered from leucorrhoeal discharge during the past three months. It was suspected that it might be due to the presence of pin-worms. *Ascarides* as a cause was thrown out in the following manner: Injections containing one drachm of the muriate tincture of iron to the pint of water had been thrown into the rectum, and no worms were obtained. The following prescription had been written:

℞ Santonin ..... gr. iij.  
Calomel ..... gr. i.  
M.

To be taken at night and followed by oleum ricini the next morning. No worms were seen in the discharges, and the conclusion was reached that *ascarides* was not a cause of the leucorrhoea in the present case. It was maintained that astringent washes were not to be thought of, or used by means of syringes in the ordinary manner, for the instrument was very apt to produce irritation, which would cause more harm than the astringent solution would do good. Thorough cleanliness was insisted upon, and after cleansing the parts, a stream could be directed into the vagina from a small syringe containing a solution of sulphate of zinc of the strength of one drachm to a pint of water. It was remarked that these cases, as a rule, get well after a certain amount of persistence.

##### EPISTAXIS—INCONTINENCE OF URINE.

A girl, *et.* 14 years, complained of suffering from bleeding at the nose two or three times daily, and from being unable to control her water during sleep. Menstruation had not commenced, nor was it believed that the epistaxis was vicarious. The incontinence was nightly, and the epistaxis almost daily, and had continued for two months. The following remedies were administered: the ergot to control the hemorrhage, the iron to affect the incontinence and support nutrition.

Fluid ext. of ergot (Squibb's) was given in ten-drop doses after meals, and muriate tincture of iron in the same amount also after each meal. The improvement was immediate and marked, for during the first week after commencing treatment hemorrhage occurred only once, and incontinence not at all. During the second week she had no hemorrhage, and wet her bed only once. At the end of that time both remedies were discontinued, and the following ordered as a general tonic:

℞ Quin. sulph. .... grs. xlviii.  
Strychnia sulph.,  
Acid. arsenious, āā ..... grs. ss.  
Acid. phosphoric dil. .... ℥ ss.  
Syr. ferri superphos. . . . q. s. ad ℥ vi.  
M. et S. Teaspoonful three times a day, after meals.

##### ARTICULAR INFLAMMATION—COLD-WATER TREATMENT —PYEMIC RHEUMATISM—ACUTE ARTICULAR RHEUMATISM—CERTAIN POINTS OF DISTINCTION BETWEEN THE TWO CONDITIONS, AND THEIR TREATMENT.

The patient illustrated the application of cold

in the treatment of articular inflammation. Four weeks subsequent to her confinement she was seized with a chill, which was followed by arthritic trouble that had been called articular rheumatism. It was remarked that there was an affection which might be called pyemic rheumatism, and that it was altogether different from acute articular rheumatism. In what way does it differ? The pyemic form begins with a severe chill or chilliness, and is characterized by the occurrence of chills, more or less severe, throughout the course of the disease. The temperature is usually exceedingly high at the time of the occurrence of the chill, even higher than when the fever has set in, which soon follows the chill. The patient before us had a chill, fever, some sweating, but not profuse; some of the joints became involved, were hot and swollen and tender; but finally one joint remained affected out of all proportion to the duration of the acute attack in articular rheumatism. That fact was regarded as a feature of pyemic rheumatism. It settles upon one or two joints in the body, and they will remain inflamed and excessively tender and swollen, although all the other symptoms of the complaint have subsided. If a case of that kind is watched, it will be found that results follow which do not belong to articular rheumatism. It was said that rheumatism did not cripple the joints affected by it, although it might exist for ten or fifteen years. Rheumatism produces violent inflammation without causing much organic change in the parts. With pyemia it is different, for there will be manifested a tendency to disorganization of the joint, showing itself first in universal inflammation of all the structures, with excessive tenderness out of proportion to symptoms found elsewhere in the body. In articular rheumatism the tenderness is not when the fever has subsided, but it is when the fever is at its height. In the case before us, the joint which remained affected was the ankle. It was enlarged in all directions instead of antero-posteriorly, as in articular rheumatism. Suspecting that the case was one of septic infection of the joint, appearing after confinement, the visiting physician was led to believe, too, that the ordinary rheumatic treatment would not prove of much avail. The patient was placed upon quinine and salicylic acid in moderate doses, and the joint was attacked by the local application of cold in the form of ice. The effect of the ice was immediate and most satisfactory, for within one hour the excessive tenderness had all disappeared. The joint rapidly assumed its natural shape. The patient bore the ice applied directly in contact with the skin, with the exception of thin layers of lint intervening, and the cold was continued for about two weeks. At the expiration of that time the cold became disagreeable, and such applications as had been previously used, iodine, etc., were substituted. The local use of ice in the treatment of acute articular rheumatism was condemned, because the pain is secondary. There is a poison circulating in the blood, and the ice does not affect the cause of the disease. It was believed that the local application of ice in acute rheumatism had a tendency to produce cardiac complications.

##### PYEMIC RHEUMATISM FOLLOWING ABORTION.

In the case before us the wrist was the part affected, and the disease yielded at once to the local application of ice. The history was as follows: The patient had been in the hospital about ten days. She had had an abortion, and about ten days subsequently one wrist began to swell and be painful. Her trouble was confined to a single joint. She was treated about

two weeks for rheumatism, but without benefit. There was no history of injury. Another feature which distinguishes these cases from rheumatism was here pointed out, namely: a rheumatic joint can be moved without causing much pain, the pain caused being more in the tissues about the joint than in the joint itself in a majority of cases, whereas in the case under examination, and so with all belonging to that class, the movements of the joint itself gave pain. Poulitices and anodyne liniments had been applied without relief, the inflammation in the meantime extending. Ice was at once applied, and the patient had received more benefit from it than from any other application that had been made. As soon as she begins to complain of pain produced by the ice, it should be removed and some form of counter-irritation employed, and for this class of cases nitrate of silver was preferred. A saturated solution was applied to the back of the joint. If vesication was produced, it was said, so much the better, and the vesication from nitrate of silver was to be preferred to anything else, because it was the best for producing subsequent absorption. It was regarded as better than tincture of iodine, because iodine so often failed to produce anything more than dense cuticle. In this case the ice was borne one week. In connection with these cases it was also remarked that for controlling pain in fibrous tissue

#### BELLADONNA AND STRAMONIUM

ointments were far more serviceable than opium. The following was recommended as an application in

#### ACUTE ARTICULAR RHEUMATISM.

R.	Hydrate of chloral.....	ʒ i.
	Salicylic acid.....	ʒ ss.
	Stramonium ointment.....	ʒ i.

#### SYPHILIS—QUESTION IN THE CASE.

The following history was elicited: There had been a suspicious sore upon the penis; suspected chancre; there was enlargement of glands in the groin upon the left side; the post-occipital glands upon the same side were enlarged, and also the epitrochlear glands of the left arm. The supposed disease was believed by the man to have been contracted seven weeks previously. There was a mucous patch in the mouth, mucous patches upon both tonsils, but there was no eruption. The original lesion upon the penis was a "little pimple," which healed readily while a mild calomel dressing was being used, but there was left a hard lump about the size of a pea. About one week ago he had connection, and the sore had broken out again. It was a question whether the mucous patches had been developed unusually early, or whether the disease had been contracted a longer time ago than was supposed. If contracted longer ago, the patient had not been conscious of having had any initial sore. It was remarked that syphilis might exist for a long time without presenting all the practical marks of the disease.

#### WANDERING GOUT—THE ALKALIES MOST BENEFICIAL IN TREATMENT—COLCHICUM—ALTERATIVES AND SPECIFICS SHOULD ALWAYS BE ACCOMPANIED BY RESTORATIVES.

It was said that the most serviceable alkalies in the treatment of wandering gout with a tendency to attack the kidneys were potash and magnesia. Of these the potash was regarded as by far the more desirable, and could be administered as liquor potassæ in half-drachm doses three times a day. In larger doses it was thought to be liable to disturb the stomach.

It was also claimed that colchicum should never be administered alone, but should be combined with some restorative, and the one the most useful in combination was quinine. The statement was made in accordance with what was held to be a general law, namely: that specifics and alteratives should never be administered alone, but should be combined with the restorative which acted best with the article employed, in order to prevent unpleasant secondary effects that might be produced by such specific if given independently.

#### DISINFECTANT AND ANTISEPTIC COUGH MIXTURE.

It was said that disinfectants and antiseptics were always indicated in cough with muco-purulent expectoration, and the following prescription was written:

R.	Potass. iodid.....	ʒ i.
	Acid. nitric dil.....	ʒ iij.
	Tr. belladonnæ.....	ʒ i.
	Acid. salicylic.....	ʒ i.
	Aq. camph.....	ad ʒ iij.

M. et S. Two teaspoonfuls in water, three or four times a day.

#### LUXATION AT THE HIP-JOINT—EASY AND SUCCESSFUL METHOD OF REDUCTION—COROLLARY.

Place the patient on his back upon the floor; flex the femur upon the abdomen until it is brought at right angles with the pelvis; then, standing astride of the patient, clasp the hands under the legs close up to the thighs and suspend the body; when the body has been raised free from the floor, the sound limb can be so balanced against the leg of the surgeon that the entire weight of the patient's body can be utilized as an extending force upon the dislocated limb, and, assisted perhaps by a trifling rotation, will draw the acetabulum over the head of the bone. In this manner the reduction was effected without the use of any force at all, and it was believed that the principle was applicable to all forms of dislocation at the hip-joint. The theory was that the so-called  $\nabla$  ligament was the obstruction to reduction, and that, when it was most fully relaxed, as it could be by flexing the thigh at right angle with the pelvis, the weight of the body was sufficient to overcome the obstruction and bring the bones into their proper relation. An advantage which the method possessed over all others was that it made the patient *particeps criminis*, and, as a matter of necessity, he became one of the defendants in the suit, in case any one was subsequently disposed to sue for damages.

A NUTSHELL COUGHED UP AFTER A LODGMENT OF OVER THIRTEEN YEARS.—Dr. J. W. Luse, of Clyde, Ohio, writes: "I was called upon to treat a child, son of Geo. and Phoebe McFarlin, of Townsend City, Sandusky Co., Ohio, in February, 1863. The boy was 2 years and 2 months old, and was suffering from an attack of bronchitis, hard breathing, and suffocation. The parents supposed the child to have inhaled a small piece of the shell of a hickory nut. The proper remedies to allay bronchial irritation were administered, with but temporary effect. Other physicians were called from time to time with similar results. The child's life was finally despaired of, as it was supposed the left lobe of his lungs was entirely destroyed. But on Tuesday, June 5, 1877, after a lapse of 13 years, 3 months, and 17 days, he coughed up the piece of the nutshell, which measured very nearly  $\frac{7}{16}$  of an inch long, and  $\frac{1}{16}$  wide from point to point, in the shape of a cross, and curved lengthways, with rough points."

## MEDICAL CERTIFICATES.

WE are not of those who despair of any good coming out of our medical Israel, but we confess that the signs of the times do not give any brilliant promises for the near future. It would seem that the struggle for precedence, the desire for reputation, and the necessity for each one looking particularly to his own interests, give the hindermost ones very poor chances for escaping their fate. When the question whether a man is to succeed or not in his profession becomes one of simple conscientious adherence to the code of ethics, there is not unfrequently much temptation for the stretching of conscience in favor of the individual rather than the principle. While the letter of the law may be strictly followed, its recognized spirit may be as effectually ignored as if there were no relationship between the two. Hence, we find some of those whom we would gladly consider as our best men constantly resorting to devices which, although not open violations of the constitution, are liable to a very suspicious construction. We are led to make these remarks as bearing more particularly upon a practice, lately very much on the increase, of allowing the publication of medical certificates in the daily papers. We cannot shut our eyes to the fact that this is one of the covert means of medical advertising which should be stopped at once. There is only one way of viewing this matter, and that is, by holding every one to account who allows his name to be thus used. No respectable agent of any drug, liquor, or mineral water would presume to use the name of any medical gentleman, in an advertisement in any daily paper, without the consent of that gentleman. We speak advisedly on this subject, and because we do so we are the more mortified for the necessity of referring to the matter at all. It is legitimate enough for any medical man to give a certificate concerning his experience in the use of any particular medical preparation for the

use of his brethren, as they will be able to appreciate it at its full value, and at the worst nothing more can be done than the commission of an indiscretion or the violation of good taste; but the ease is very different when an appeal is made to the general public with the opinions of "distinguished physicians." The latter is so plainly an advertisement that the motive of allowing the name to appear is open to the gravest suspicion and the severest criticism. Even if it is claimed that such certificates are made in good faith, we ask if it is professional to recommend to the public any wine, mineral water, or medicine, for indiscriminate use?

In talking with an agent, not long since, in regard to one of these certificates, we were assured that medical men do not object to the widespread publication of their names, but that they frequently offer the use of their names of their own accord. In fact, some have gone so far as to hint in the broadest possible manner that such a publication would be rather desirable than otherwise.

It is well known that there are men who will sign everything that comes along, whether it is a certificate as to the efficacy of a pill, or the hygienic influences of a particular sewing-machine; but these names are not of much value to enterprising advertisers when they can obtain much better men with such little trouble.

## AMERICAN DIPLOMAS ABROAD.

IT would appear that our English cousins are never to learn what constitutes a true medical diploma in this country. The name American diploma is so constantly associated in their minds with the bogus certificates which are sold by *quasi* institutions here, that it is difficult for them to understand that we have any other legal guaranties for medical education. The facts of this abominable traffic have been brought to the notice of the profession across the water time and time again, and it should be pretty generally understood that the quacks who settle in London, and who claim to be "American" physicians, are no more recognized here than they are there. The profession here has done its best to check the bogus diploma trade, and to a certain extent it has succeeded. It should not be held accountable for what it cannot control; and further, it is hardly fair to class what are really well-educated medical men here with a class whom even our English brethren acknowledge are transparent frauds.

Every little while a new case comes into the London courts under the sensational caption of "Another American Physician in Trouble," and we read the account to find that a "Dr." Hamilton or "Dr." Jones has been guilty of unlawful conduct in assuming a spurious title, etc., etc.; and then, in the course of the comments upon the value of American diplomas and the laxity of requirements for a medical degree,

the usually absurd questions are asked if there be such a recognized medical school in the United States as the Metropolitan Medical College, the School of Medicine of New York, the Medical University of Philadelphia, *et id omne genus*. We protest that we have had enough of this, and think it about time that our critics should inform themselves of the true state of medical affairs in this country before indulging in further remarks.

## Reports of Societies.

### NEW YORK ACADEMY OF MEDICINE.

#### SECTION ON PRACTICE OF MEDICINE.

*Adjourned Meeting, May 25, 1877.*

DR. GOUVERNEUR M. SMITH, CHAIRMAN.

#### THE TREATMENT OF SCARLET FEVER.

THE subject for discussion being the ordinary complications, the treatment of scarlet fever, and the treatment of the ocular and aural complications,

DR. J. LEWIS SMITH spoke with reference to the ordinary complications as follows: He directed attention first to the *nervous complications*, which, when present, were accompanied by rapid pulse, marked elevation of temperature, and occasional eclampsia, and rendered the cases more than ordinarily grave. The causes of this complication were noted under two heads:

*First*, Active congestion of the cerebro-spinal axis.

*Second*, Direct disturbing influence of the specific poison upon the nervous system.

The earlier and milder eclampsia was not usually serious, but the protracted and later eclampsia was exceedingly grave. There was a predominance of blood poisoning as a factor in causing this complication, however early it might appear, but in the early cases it was rarely fatal. Eclampsia occurring in the later stages was usually fatal, and was dependent upon the scarlatinal poison. It had been observed that eclampsia occurring in scarlet fever always proved fatal except when occurring before or just in the beginning of the eruptive stage, but Dr. Smith was of the opinion that by the combined use of the bromides and chloral occasional cases of eclampsia occurring at a later period had been saved. By far the larger proportion, however, of cases with this complication perished, except when it occurred at the initial stage of the disease.

#### THROAT COMPLICATION OF SCARLET FEVER.

Inflammation commencing in the absorbents and lymphatic glands along the side of the neck, and extending to the connective tissue, which was serious in proportion to the induration and swelling. This complication was produced by the absorbents taking up the poisonous material upon the mucous surface. It was believed to be a less frequent complication since it had become customary to disinfect the fauces as a part of the treatment of scarlet fever, than it was in former times. There had been very much less of that complication in New York during the last five or six years than prior to that date, and it was explained by the use of the local disinfectant treatment. Formerly the sore throat of scarlet fever had been treated largely by means of external applications, but since the internal treatment by means of antiseptic and disinfectant applications had been employed, the cervical cellulitis

had been very much less than formerly. In this connection allusion was made to the fact that the type of the disease might change. Scarlet fever changed its type the most frequently of any disease, and diphtheria came next in order. It had been the case that the mortality from scarlet fever had been very much less of late years than formerly, and it might be that it was because the type of the disease had changed rather than due to any improved method of treatment.

The throat complication, cervical cellulitis, etc., produced death in one of three different ways:

1. By producing exhaustion as the result of ulceration, and sloughing and suppuration, with or without hemorrhage.

2. By causing edema of the larynx, either from pressure directly upon the larynx or upon the pneumogastric nerve.

3. More frequently by retarding the flow of blood from the brain by pressure upon the jugular veins. Such pressure gave rise to congestion of the cranial sinuses, veins, and capillaries of the brain and meninges, and perhaps, as a result, gave rise to transudation of serum.

Dr. Smith was of the opinion that in a certain proportion of cases, in which it was formerly supposed that death had been due to the effects of the scarlatinous poison, it had occurred as the result of pressure upon the jugular veins, produced by the cervical adenitis and cellulitis.

Reference was made to cases in which death was caused by conditions secondary to the pressure produced by an enlarged bronchial gland upon the veins at the point where they converge to form the descending innominate.

#### DIPHTHERIA AS A COMPLICATION OF SCARLET FEVER.

Diphtheria as a complication of scarlet fever had been of very frequent occurrence in New York, as it would be in any locality where diphtheria had prevailed and scarlet fever made its appearance. This complication occurred as early as the middle or at the close of the first week. In this connection reference was made to the fact that diphtheritic virus might remain in a room for two months and then give rise to the disease; the scarlatinous poison might remain in a room three months and still retain the power of producing the affection.

Scarlet fever invited diphtheria, but diphtheria did not return the compliment.

Sometimes, where the sanitary conditions were apparently good, where there had been no exposure to diphtheria outside of the house, scarlet fever had recurred, became complicated with diphtheria, and then the diphtheria became disassociated from the scarlet fever and appeared as an independent disease.

Dr. Smith referred to illustrative cases; four cases of diphtheria occurring without scarlet fever, the latter disease, however, bringing the diphtheria into the house.

Rheumatism was another complication; more commonly appeared in the joints of the upper extremities; was not usually of much gravity, and did not seem to retard the convalescence of the patient.

Gangrene of the mouth had been observed in a few instances; perhaps no more apt to occur as a complication of scarlet fever than of any other disease which equally prostrated the patient. Enteritis occasionally occurred as a complication; a relaxed condition of bowels was common in cases of malignant scarlatina, but the patients usually did very well when the discharges were controlled.

There was also a liability to the occurrence of se-

rous inflammations independent of kidney disease. Of course in acute Bright's disease there was a marked tendency to the occurrence of serous inflammations, like pericarditis and endocarditis, etc., usually attributed to the effect of the urea circulating in the blood; but when the kidneys did not become specially involved, such tendency to serous inflammation might be developed in connection with scarlet fever.

Nephritis was commonly regarded as a sequel to scarlatina, but Dr. Smith was inclined to regard the kidney disease as a complication, and one of earlier occurrence than physicians usually believed. It was thought that if the urine was examined at each visit it would be found that albumen was present before the eruption had faded away. Physicians, generally, were not in the habit of examining the urine until other symptoms of nephritis, as anasarca, etc., were developed; hence, it was believed that it was a complication of more frequent occurrence than was usually supposed.

#### GENERAL TREATMENT OF SCARLET FEVER, AND ITS ORDINARY COMPLICATIONS.

DR. WM. H. THOMSON, in speaking of the general treatment of scarlet fever, and of the ordinary complications, remarked that several years ago, when he had charge of a large number of patients at Quarantine, he had pursued three different courses:

1. To do nothing, except give the patients milk, with or without lime-water, and some placebo for a moral effect.

2. To use carbonate of ammonia freely.

3. To adopt the chlorine treatment, consisting in the use of chlorate of potash and dilute muriatic acid.

The diet in all cases was the same, namely, milk.

The complications were treated upon general principles. He was very much impressed in favor of the chlorine treatment in consequence of his experience in the treatment of scarlet fever at that time, extending over a period of time two years in length. In a certain class of cases, he came to regard with favor the treatment by the free use of the carbonate of ammonia. Since that time, his general treatment of scarlet fever had been by means of the chlorine plan. In exceptional cases he employed the carbonate of ammonia, and it was thought with noted benefit. For instance, there were certain cases in which there was marked tension of the pulse; the tension, perhaps, within the first two or three hours, being as high as is found in Bright's disease of the kidney or in gout. Marked tension of the pulse was regarded as characteristic of scarlet fever alone among the eruptive fevers, and was sufficient of itself to excite suspicion regarding the presence of the disease. When that condition was markedly developed, it was believed that there was a greater liability to hemorrhages occurring in the skin in the viscera, perhaps in the serous membranes, and perhaps in the substance of the heart itself. There was a tendency to the production of minute emboli and thromboses of the veins, and it was possible that the carbonate of ammonia might prevent hyperinosis of the blood with especial tendency to deposits of fibrin. But the chlorine treatment had so much the advantage in the statistics over the other plans adopted, that he had continued to employ it up to a certain date, hereafter to be mentioned.

The treatment consisted in the administration of grs. lxxx. of chlorate of potash and  $\mathfrak{z}$  ij. of the dilute muriatic acid every twenty-four hours, largely diluted with water; one quart being the quantity ordinarily used. Lymphatic enlargements complicated but very few cases under that treatment.

Since, he had somewhat modified the plan by the substitution of bromine for chlorine. The reason for the substitution was because bromine belonged to the same series of antiseptics and disinfectants as chlorine, and was far more powerful. The chlorine series acted upon chemical principles, setting oxygen free in the nascent state; hence doubly disinfectant.

The carbolic acid group, salicylic acid, oil of cinnamon, ginger, cloves, of wintergreen especially, all being closely allied, were disinfectants, but were to be chosen in the treatment of suppurative inflammations to prevent decomposition of pus, whether the suppurative inflammation was internal or external.

But against communicable diseases they failed utterly in comparison to the chlorine series. They were regarded as useless in the treatment of diphtheria, cholera, etc., for that reason; whereas chlorine was prompt in its action against cholera and communicable diseases.

Several years ago Dr. Thomson began to treat diphtheria by the use of bromine. His impression was that if we were to obviate the more serious developments of communicable affections, like scarlet fever, diphtheria, etc., it must be done by preventing changes in the blood, which were very closely allied in character in each disease. In bad cases of scarlet fever and in bad cases of diphtheria there was a septic condition of the blood, caused by the decomposition of the albuminous elements, quite analogous to fermentation and putrefaction.

Probably, in the majority of cases of death from scarlet fever, death was due to true septicæmia, rather than to poisoning by the specific agent of the disease. The same was true of diphtheria, bad cases of measles, and of small-pox. It was believed that the blood condition in all these cases was very analogous, and therefore should be treated by the use of antiseptics internally.

Bromine being far more powerful as an antiseptic than chlorine, was used both locally and internally in the treatment of diphtheria. Although the Doctor had not much reason to think that the chlorine treatment had not been as successful as possible perhaps in the treatment of scarlet fever, yet he had, of late, relied upon the use of bromine. Since he had adopted its use he had not seen cases of lymphangitis, and there was a full concurrence in the remarks of Dr. Smith, to the effect that the throat complication, the swelling of the glands about the neck, etc., had been much less frequent since the internal as well as the external use of antiseptics.

So far as general treatment of scarlet fever was concerned, Dr. Thomson placed first and foremost among the indications the internal use of antiseptics belonging to the chlorine class—his own preference being for the bromine, having formerly employed chlorine.

The manner of using the bromine was as follows: Dr. J. Lawrence Smith's solution was employed, consisting first of a saturated solution of bromide of potassium in water, and to  $\mathfrak{z}$  ij. of that  $\mathfrak{z}$  i. of bromine was added very slowly, shaking the bottle constantly while making the combination. It was better to add half of the quantity of bromine first, and then let the bottle stand for an hour or more before the remainder was added. When the bromine was dissolved in that manner, the bottle was to be filled with water until a four-ounce mixture was made. The solution thus prepared could be again prepared for administration by combining it with water in any proportion desired.

For internal administration  $\mathfrak{z}$  i. of the solution to  $\mathfrak{z}$  i. of water was used, and of that a teaspoonful was given in a tablespoonful of sweetened water,

p. r. n. The solution should be kept in a dark place. As a local application, equal parts of the solution and glycerine could be employed, or, in serious cases, the solution could be applied clear. The odor of diphtheria was entirely destroyed by the local application of the bromide solution.

Dr. Thomson also thought well of the suggestion made by Dr. Hood, of London, that occasional purges of calomel and jalap should be given; three grains of the former combined with five grains of the latter. The antiseptics could be discontinued until catharsis was produced, and then resumed.

The suddenness of the onset of the disease, and the rapidity with which it affected the cerebrum in certain cases, producing rapid rise in temperature, perhaps to 104°, 105°, or 106° F. or more, led him to advise very strongly the immediate douche of ice-water to the head. Wrap the child in blankets and donche it over the head until the pulse changes its tension. It was believed that there was a strong resemblance in the pulse in these cases to that exhibited in puerperal eclampsia. There was the same indication for relief by the immediate contraction of the twigs of the arterial neck. The steady use of cold water in this manner until the pulse changed its character, when high tension was present, it was believed, would be followed by good results in cases of scarlet fever at any period of the disease. When the temperature reached 104° F. the cold wet pack was recommended, and coupled with the statement that he had never seen any harm follow its use. The cold bath was not recommended; the cold wet pack was believed to be all that was necessary. Take a sheet, wring it from water at the ordinary temperature, wrap the child in it, and over that lay one wrung from ice-water. The prompt manner in which the symptoms had improved under such management had led him to regard the wet pack as one of the great therapeutic resources for that class of cases.

There was a tendency to parenchymatous degeneration of the internal organs, in connection with a high temperature, in scarlet fever, more marked than in typhoid fever. There was a greater tendency to blueness of the surface in a case of scarlet fever, with a temperature of 105° F., than in a case of typhoid fever with a temperature of 108°, 109°, or 110° F. Grave symptoms associated with high temperature, however, were regarded with more favor than grave symptoms without high temperature; for, as a rule, these cases took a more favorable turn. Those cases in which tympanitis, bronchitis, hemorrhagic tendency, constipated condition, and small, rapid pulse were present, with a temperature of nearly 101° F., were to be regarded as much more unfavorable than those in which similar symptoms were present in connection with high temperature.

Dr. Thomson recommended that, from the very commencement of the disease, the body should be oiled over three times a day. One reason was because it was one of the most effectual means of relieving the itching of the skin and the excessive restlessness of the patient, the restlessness being due to irritation of the peripheral nerves, caused by the heat of the skin. Such irritation was relieved more readily by oiling the surface than by sponging with tepid water. Another reason for resorting to the oiling was because it was truly antipyretic—it reduced the temperature. Another reason for its use was because of the close sympathy existing between the skin and kidneys. It was thought that in scarlatina there was present for the time a condition very similar to that developed by varnishing the skin of an animal.

In scarlet fever there were two periods in which albumen was found in the urine. It was found in the febrile stage, when it was of no more significance than when found associated with pneumonia. But subsequently an albuminuria was present, invariably at the end of the second week, perhaps not reaching its maximum until the fourth week, which spoke of congestion of the kidneys, and oiling of the surface of the body was one of the best means for relieving that engorgement, because the renal trouble was mainly due to the condition of the skin. The oiling kept the glands of the skin in an active condition.

Another reason for oiling the skin was because it removed the pressure from the subcutaneous vessels, and thereby promoted diaphoresis. With reference to the nephritic complication, no case was to be despaired of in its acute stage, for recoveries from apparently the most desperate conditions had taken place. Reference was made to cases in which suppression of urine had continued for seven and nine days, and yet recovery followed. The measures to be adopted for the relief of the nephritis were: oiling the skin; the hot-water pack; dry cups; wet cups, if necessary; counter-irritation by means of spoons heated in hot water, and applied momentarily over the kidneys; free use of infusion of digitalis; and, after diaphoresis, large injections of warm water. The injections were to be preferred to purgatives, for the reason that the action of the warm water favored the evacuation of water from the bladder. Large injections of warm water, a quart, perhaps, might be used as many as six times a day, and the final success in passing water might come with the last injection. The infusion of digitalis should be given to children in doses very nearly as large as would be required for adults.

#### TREATMENT OF OCULAR AND AURAL COMPLICATIONS.

Dr. H. D. Noyes remarked, with reference to the ocular and aural complications in scarlet fever, that they might occur early or late in the course of the disease, but usually late, especially with reference to the eye. The mode of origin was in the first place direct; that is, by immediate extension of the inflammation from the skin to the mucous membranes of these organs. That was by far the most frequent mode in which the eye and ear became affected.

*S. conil.* They became affected from blood-poisoning, and the blood-poisoning occurring as mæmia, embolism, or pyæmia.

The affection of the ear was most common and occurred at the earliest period, the affection of the eye occurring more commonly at a much later period. In the inflammatory affection of the ear and eye, which occurred simply as the result of an extension of the inflammation to those organs, there was nothing peculiar in the pathological process. The same pathological conditions were found without scarlet fever as occurred in connection with it; but the peculiar and important fact in the scarlet fever cases was that we were dealing with organs whose integrity was essential, and whose power of resistance was greatly impaired in consequence of the general condition of the system. An acute process, under such circumstances, was likely to be much more destructive, simply because the patient was in an unfavorable condition of health. As far as the actual lesions were concerned in the eye complications, there was, more commonly, inflammation of the conjunctiva, of the lids, and of the cornea. There was, however, no special line of treatment for such cases of inflammation, other than that which would be appropriate for the treatment of the same difficulty occurring in children without scarlet fever,

except that we were to take into consideration the general condition of the patient, sustain nutrition, and do what was possible to antidote the poison, and thus facilitate the action of local remedies. Any severe local applications to the eye were always out of place. If nitrate of silver was used it must be only in the weakest solutions—not more than grs. v. to the i. of water, and much more commonly grs. ij. to the i. of water. As a rule astringents of only the simplest kind should be employed, such as alum, etc.; and the sulphate of zinc, and sulphate of copper should be ignored, as they were liable to do mischief. Attention should be especially directed to the cornea, for it rapidly broke down, and became destroyed. It was needful, therefore, to use a local anodyne in the form of sulphate of atropia grs. ij. to the  $\zeta$ i. of water, of which from one to three drops were to be dropped into the eye three times a day; and in addition, the eyes were to be bathed freely with warm water. Such was the usual outline of treatment for affections of the eye in connection with scarlet fever. For the photophobia which might be present a moderate exclusion of light was recommended. The ear trouble more commonly produced disastrous consequences, and was developed in two ways: 1. By extension of the inflammation and giving rise to otitis externa; and 2. By extension from the pharynx up the Eustachian tube, and terminating in otitis interna. The history of otitis interna and otitis externa in connection with scarlet fever was precisely the same as when they occurred without scarlet fever, with the exception that the issues broke down more rapidly. It therefore became needful to make use of warm fomentations, and the warm douche externally, and very carefully to watch the condition of the drum membrane. If upon inspection it appeared sodden and swollen, and showed any signs of an acute process going on inside, it was far better to make an unnecessary puncture of the tympanum than to leave the ulcerative process to complete itself in the natural manner. The puncture did no harm, and the tissues would not be destroyed to anything like the same degree as if the ulcerative action was permitted to complete itself, thus allowing the pus to escape by the natural process.

In the same manner extension of the inflammation might take place into the mastoid cells, and the surgeon should carefully inspect the mastoid process, examine with the finger, and if any tenderness was present should, without hesitation, resort to leeches. If a marked degree of tenderness was present, he should make a free incision over the affected part.

Dr. Noyes did not hesitate to recommend injections through the nostrils in cases which seemed to demand local treatment of the nasal passages, notwithstanding so much had been said concerning the inefficiency and the deleterious results which might follow the use of the nasal douche.

When suppurative action occurred in the middle ear, the pus should be evacuated thoroughly. Sometimes it was necessary to resort to inflation with the Politzer bag in order to accomplish a thorough removal of the pus. In children such inflation was very easy, because all that was necessary was simply to place the tube of the bag in the nostril, shut the nose over it, have the mouth closed, and then simply blow; no water or swallowing being necessary. In that manner secretions could often be driven out from the middle ear better than with the syringe. The syringing should be by a copious stream of water.

When the secretions were removed by the simple douche, very warm water should be employed—99° F., perhaps a little higher. For syringing to be effi-

cient, not less than a two-ounce syringe should be used, having a long, slender nozzle, to which should be attached a simple bit of rubber tubing, to prevent the terminal extremity of the nozzle from doing injury.

The treatment of the aural complication when it became chronic, when perforation of the tympanum had occurred and a chronic discharge existed, it was not thought necessary to dwell upon.

There was another class of cases in which blood poisoning was the cause of the eye complication. The condition was that of neuro-retinitis, due to the Bright's disease incident to scarlet fever. The prognosis in those cases was usually good; sight was usually recovered, partially, at least, and sometimes completely. It usually occurred without marked symptoms, as far as the patient was concerned, saving, perhaps, a certain amount of flashes of light and a certain amount (perhaps very trifling) of dimness of vision. There was no condition of the ear which stood in an analogous relation to that affection of the eye.

Dr. Noyes, noting the value of anointing the skin, suggested the use of borax and glycerine, inasmuch as borax was a powerful solvent of the epidermis. It could be used in the proportion of  $\zeta$ i. of borax to  $\zeta$ i. or  $\zeta$ ij. of glycerine, and perhaps might assist the skin in resuming the proper performance of its function.

Reference was also made to the grayish, membranous exudation, pellicle-like, so frequently seen upon the different mucous surfaces, and called diphtheritic, and the question raised whether it was not really the product of inflammatory action, and not true diphtheritic exudation.

Dr. Thomson remarked that he had frequently seen the same kind of exudation in connection with typhoid fever, and under such circumstances he always expected trouble in the ear.

With reference to the borax solution, he was of the opinion that there was no use for it which would be of special value.

It was well known that desquamation in scarlet fever occurred last about the roots of the nails, and that the scales which fell off had the power of communicating the disease. It might be, therefore, that the strong antiseptic properties of the borax could be made available, hence the propriety of having the patients apply the solution recommended to the hands and feet for that purpose alone, namely, to assist the desquamation, and at the same time destroy the poison existing in the epidermal scales.

Dr. O'SULLIVAN remarked that he had often succeeded in tracing scarlet fever in the public schools by the condition of the cuticle about the roots of the nails. He further referred to isolation as a means of prevention. Reference was also made to the fact that he had seen many cases in which albumen had not been found in the urine in the later stages of the disease, although regular and frequent examinations were made.

Dr. HADDEX referred to the fact that scarlet fever could be communicated by means of cats' fur, and that the disease could be contracted by cats from children. With reference to bromine, he was especially pleased with its action, and had noticed that it did not cause soreness of the lips and mouth, as the chlorine preparations sometimes did.

THE CHAIRMAN raised the question of prophylaxis, and spoke of the protective influence of bromine in the management of hospital gangrene. Had any one any knowledge of any agent that could reasonably be employed to protect against scarlet fever?

Dr. THOMSON remarked, with reference to the use of belladonna as a prophylactic agent against scarlet

fever, that it was one of the oldest of heresies. He did not believe there was any way to prevent the development of communicable diseases when they were fairly introduced into the system; we could only prevent the severity of the development.

DR. SELL referred to the use of the bisulphite of soda in the treatment of scarlet fever, and also to the combined use of gelsemium and aselepias, given in warm water, to effect diaphoresis in febrile cases.

The Section then adjourned to meet in October.

### SHORTENING IN FRACTURES, AND BILATERAL SYMMETRY.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—I read your editorial on "Shortening in Fractures" with much interest, and also the few remarks that are reported of the discussion of the subject before the American Medical Association.

There is to my mind one all-important point bearing upon this matter which I think has not received due attention, and that is the question of bilateral symmetry as to length in those who have never been injured.

I wrote some remarks upon "Measuring," which are published in the *Medical Times* of this city, Jan. 16, 1875, for the express purpose of calling attention to the then forthcoming paper of Dr. W. C. Cox (see *Am. Journal Med. Sciences*, April, 1875, p. 438). Dr. Cox gives the measurements of both sides of 54 uninjured persons, and the differences range from 0 to  $\frac{1}{4}$  of an inch, exact symmetry only existing in six persons. Sir James Paget, after reading my remarks, wrote me in substance that he had long since abandoned the use of the tape and relied upon the eye, thus practically recognizing the fact that the thing to do was to bring the patient into proper relations with himself as it were, instead of trying to mould him to a mathematical standard.

A Long Island Hospital surgeon, I think, has also taken up this subject and confirms the statements made. Some time ago I wrote to Washington hoping to get the army and navy authorities to take the matter up. They have published a vast deal upon anthropometry, but nothing that I can find in this particular direction. I hope that they will take it up, for its importance in a medico-legal view, I think, cannot be exaggerated.

Very truly,  
WILLIAM HUNT.

## New Instruments.

### A NEW TRUSS FOR FEMORAL HERNIA.

By W. B. DE GARMO, M.D.

Those of the profession who have had experience in the treatment of femoral hernia appreciate the many difficulties attending such an undertaking, and are aware that it is almost impossible to select from the many trusses one which will retain hernia of this character fully and with any degree of comfort.

In constructing trusses for femoral hernia, the prevailing idea seems to have been to make the pad large enough to keep the hernia out of sight, and this, in fact, is about all they do, except to make undue pressure upon the vessels and nerves of this region; they are exceedingly uncomfortable to wear, move from

their place easily, and fail in most instances to retain the hernia perfectly.

In devising the truss represented in the accompanying cut I have endeavored to rectify the faults mentioned. The form of spring which I have found most convenient and successful is that known as the English pattern, which passes around the hip opposite the affected side. To the end of this is attached a movable curved arm, as shown in the cut; the movements of the latter upwards and downwards are limited by the clasp partially surrounding the main spring. To the larger end of this arm is attached a thin bar of steel, which carries two screws, with nuts beneath the plate on the hernial pad; the nuts move easily in a groove beneath the plate, even under strong pressure.

The pad differs in shape from those in ordinary use.

Its size is only one-third larger than represented in the cut; two thirds of its inner surface is thin and flat, the remaining one-third being quite prominent.

It is designed that the flat surface shall rest over Poupart's ligament, and the prominent portion pass immediately beneath. In this position the pad is securely held, and the hernia is completely retained without discomfort to the patient.

The advantages claimed for this truss over all others are:

*First.* Safety. It holds the hernia more secure, and with proportionately less pressure than ordinary trusses.

*Second.* Comfort. The combination which attaches the pad to the spring, allows a relative change in position of the latter in sitting or stooping, without displacing the former or crowding it against and compressing the femoral vessels.

*Third.* Ease in fitting. Every part can be shaped to suit individual peculiarities in form, after which it is perfectly self-adjusting.

114 EAST TWENTY-FOURTH ST., JUNE 6, 1877.

## ARMY NEWS.

*Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from July 22 to July 28, 1877.*

KINSMAN, J. H., Captain and Ass't Surgeon. Leave of absence extended one month. S. O. 165, Division of the Atlantic, July 26, 1877.

MATTHEWS, W. C., Captain and Ass't Surgeon. To proceed to-morrow to Boise City, Idaho, and join Major Greene's command with the least possible delay. S. O. 88, Division of the Pacific and Department of California, July 17, 1877.

BUELL, J. W., 1st Lieut. and Ass't Surgeon. So much of par. 5, S. O. 127, C. S., from these headquarters as directs him to accompany Companies D and L, 10th Cavalry, to Fort Clark, is revoked. S. O. 129, Department of Texas, July 16, 1877.

**THE TREATMENT OF CLUB-FOOT AND A SUIT FOR MALPRACTICE.**—The case of Joseph W. Harriman vs. Eugene F. Sanger, was lately tried in the Supreme Court of the State of Maine. The plaintiff, a bright intelligent boy of seven years, had talipes equino-varus, and was operated on by Dr. Sanger on May 22, 1871, the tendo achillis being divided in the usual manner, and the modified scarpa-shoe adjusted. The subsequent treatment consisted in directions given to the mother, adjusting other shoes, constructed in Bangor, under direction of defendant, etc. As the parents were unable to pay for the proper appliances, and, indeed, did not compensate the doctor for his services in any way, the visits were discontinued. Dr. Sanger, however, generously paid for the scarpa-shoes and other appliances out of his own pocket, and made several visits gratis. Notwithstanding all this, the plaintiff, who sues by his "next friend," his father, E. K. Harriman, a shoemaker by trade, and also suffering from distorted feet, claims from defendant the sum of seven thousand dollars (\$7,000) for malpractice in not using the ordinary skill when operating, and subsequently neglecting to take proper care of the patient's feet.

The chief point made by plaintiff's counsel was, that the defendant should have followed and recognized the theory and practice of Dr. Lewis A. Sayre, Professor of Orthopædic Surgery in the Bellevue Hospital Medical College, New York.

Now, Dr. Sayre certainly differs from other specialists in many particulars. He believes that in all cases of congenital talipes the muscles on the side of the foot, opposite to the side towards which the foot is distorted, are paralyzed, and the foot is distorted by the opposing muscles contracting with only their normal degree of force, and that all such cases can be cured without resorting to tenotomy, healthy action being restored by friction, electricity, etc. An improved shoe, with ball and socket joint, was produced, and it was claimed that the surgeon should have used it instead of the other shoes, which only gave lateral motion. Complaint was also made that even if it was necessary to divide the tendon, it should have been done without severing the theca, and that the operation should have been performed without spilling any blood, or, at most, but a drop or two, whereas in this case much blood was lost.

Many experts were called from various parts of the State, who testified that it is beneficial, and in many cases absolutely necessary, to cut tendons. Doctors Hill, of Augusta, Tewksbury, of Portland, and Robinson, of Norridgewock, fully sustained the defendant's treatment of the case, and they, with other surgeons, asserted that benefit has resulted from this particular operation, and that a small loss of blood is not injurious, and, in fact, immaterial. No one of the surgeons called claimed to have sufficient skill to cut the tendon

without severing the theca, and while some would not cut the theca if it could be avoided, others regarded it as immaterial whether it was cut or not, nor did they regard any pattern of shoe as indispensable.

Dr. Laughton, for the plaintiff, testified that he had operated four times, but had never seen three of the patients afterwards, and the fourth he visited only three or four times. He cut the tendons in every instance, and applied shoes with worsted tape for extension.

Dr. Seavey, for plaintiff, stated that he had never operated or used any kind of shoe; still, he favored Dr. Sayre's theory and shoe.

Dr. Jewell, who was present at the operation, says that defendant spilled no more blood than was usual in such cases.

Upon the point of want of ordinary care or neglect on the part of the defendant, most of the surgeons testified that when the operation had been performed, the foot adjusted in the shoe, and proper directions given to the nurse or person having care of the child, and everything seems to be doing well, it is not gross neglect on the part of the surgeon to discontinue his visits until sent for. The defendant testified that he visited the child on the 23d of May, the day after the operation, and adjusted the shoes, and that he called on the 4th, 11th, and 17th of June, and found everything doing well; that there was no neglect of the case up to the time that he left it, and that he discontinued his visits because the parents would not pay for what was necessary in the case. In short, that the present condition of plaintiff's feet is chargeable to the neglect of the parents and not of the surgeon. The jury returned a verdict for the defendant.

As there are many surgeons, both in the United States and in Europe, who differ materially in the treatment of club-foot, the argument of plaintiff's counsel stands for naught. According to Stromeyer, the rationale of the operation is as follows: The tendon being divided, its separated extremities heal by a new connective tissue, which renders it longer, and which, while recent, may be stretched to any desired length. The antagonist muscles, already wasted and inert, are relieved from a constant state of tension, and are enabled to resume their natural functions. This practice is followed by many eminent surgeons, some of whom, in a case like plaintiff's, might even divide the tendons of the tibialis posticus, tibialis anticus, and flexor longus digitorum.

On the second point made by counsel, we cannot see how defendant has neglected to take proper care of plaintiff's feet. He testified that he used all due diligence in attending to patient after the operation, not only visiting him on the 23d of May, 4th, 11th, and 17th of June, but even performing a work of supererogation in paying for the necessary appliances out of his own pocket, the scarpa-shoe alone costing ten dollars and sixty cents. The non-recovery of the patient was certainly due, not to want of skill in operating or subsequent neglect by the surgeon, but to the neglect of the parents, or, rather, to their parsimony in refusing to pay for the necessary apparatus and physician's fees.

**NINETEENTH ANNUAL REPORT OF THE WASHINGTONIAN HOME, BOSTON, MASS.**—In the summer of 1857 a small number of gentlemen, after consultation, formed the nucleus of a Home for Inebriates, and appointed a list of officers. Dr. Day was elected superintendent, and in May, 1858, he made an elaborate report, in which the principles were enunciated on which the institution has been conducted. The whole number of patients treated from the inception of the Home up to April, 1877, has been 5,233, and it is estimated

that more than fifty per cent. of the number admitted are permanently cured. This is very gratifying to the managers, for there are few if any institutions in the world which can show such a record. The man or woman who seeks an inebriate asylum is not the occasional drunkard, or even the inveterate tippler, but generally a person whose moral and physical natures are almost a total wreck, whose appetite for intoxicants cannot be restrained by the appeals of family or friends, and who is totally lost to any sense of moral responsibility. Under the rules, those placing themselves under the care of the Home are considered patients who have submitted themselves for medical treatment. They are under the orders of the Superintendent, and must not leave the building without his consent. All the moral and hygienic appliances at command are employed for the benefit of the patient, who must abstain entirely from the use of intoxicants of every nature. The Washingtonian Home is an elegant building of four stories, situated on Waltham Street, and having a frontage of eighty-two feet. It is heated by steam, has a hospital and chapel, and is fireproof throughout. Nothing that might conduce to the health or general welfare of the inmates has been omitted, the entire building being fitted up in a neat and substantial manner, and every possible improvement introduced.

**EMPHYEMA AND INCISION OF THE CHEST.**—Dr. J. H. Pooley, Sr., of Dobbs' Ferry, N. Y., writes: "As the treatment of emphyema by aspiration and incision is now earnestly engaging the attention of the profession, the following case may prove interesting to some of your readers. About four months ago I was called in consultation to see a boy about six years old, who had been suffering from a severe attack of pleuro-pneumonia. When I first saw him he had not been able to lie down for several days and nights. He was supported on his mother's lap, had entire loss of appetite, great dyspnoea, rapid pulse, high temperature, and hectic fever—in short, was almost moribund. I diagnosed considerable fluid in the left side of the chest—probably purulent—compressing the lung, and pushing the heart to the opposite side. I proposed making a free incision in the intercostal space, where there was some redness and fulness of the integument. The attending physician and parents wished me to do what I thought best, as it seemed impossible for him to live much longer in such a condition. I directly cut between the ribs below the nipple, and evacuated nearly two pints of purulent fluid. His most distressing symptoms were soon relieved; he lay down that night and rested tolerably well. He was ordered quinine and iron, every six hours, with nutritious diet, beef-tea and milk-punch; soon after, cod-liver oil, and made a rapid recovery. The discharge continued for five or six days, when the wound healed. The expansion of the lung took place gradually, and he is now in good health, showing only a scar on his side and a slight retraction of his chest. Perhaps we cannot often meet with such a favorable result, but it certainly ought to encourage us to repeat this plan of treatment."

**DEATH FROM CHLOROFORM.**—A death from chloroform occurred at Mercer's Hospital, London, June 25th. The patient was an intemperate man, a waiter and billiard marker, aged 27 years. The occasion for the administration of the anæsthetic was the firing of the knee joint for synovitis. Accordingly, on the morning of the 25th, after having given the man, who was rather nervous and excited, an ounce of undiluted whiskey, chloroform was administered by the experienced chlo-

roformist to the hospital (the apothecary), by means of a Skinner's inhaler. Very soon the patient began to struggle, and within three minutes was under the influence of the anæsthetic. Almost simultaneously, and before any operative steps were taken, a peculiar change in the man's expression was noticed; the face became livid, and at the same moment it was reported that the pulse had become very weak, and then that it had stopped. The tongue was immediately drawn forward, the face and chest slapped with wet towels, a simulating enema given, and nitrite of amyl held to the nostrils, etc. Artificial respiration by Sylvester's method was at once commenced, and vigorously carried on for an hour and fifty minutes; but, although a few gasps and inarticulate sounds occurred, no sign of returning life appeared to reward the persevering efforts which were had recourse to for his restoration. An inquest was held on Wednesday; and the jury, having heard the medical evidence, returned a verdict that the deceased "died whilst under the influence of chloroform, in consequence of fatty disease of the heart." The *post-mortem* examination revealed an advanced stage of fatty deposition upon, and degeneration of, an enlarged heart. There was also a layer of fat on the pericardium, and old pericardial adhesions. The walls of the heart were pale and flabby; that of the right ventricle was thinner than normal. The cavities were dilated and empty. The valves were perfectly healthy, but the aorta was atheromatous. The lungs were extremely congested, and the base of the right hepaticized and bound down by firm adhesions. The apices of both contained numerous nodules of caseous matter, which in several places had softened into small vomice. The liver, kidneys, and spleen were enlarged and congested. There was chronic gastritis and inflammation of the mucous membrane of the ileum. The coroner and jury and the legal adviser of the deceased widow expressed their opinion that the chloroform was properly administered, and that no blame was in any way attributable to any of the staff of the hospital.

**THE DANGERS OF ETHER.**—It has always seemed to us the height of folly to declare there could be no danger in any anæsthetic. The lesson taught by the late death from nitrous oxide has, it is to be hoped, been well learned, and we shall in future hear less of the absolute safety of any agent capable of depriving a person of all sensation. Some cases in which ether has been followed by alarming symptoms have lately been recorded. They have been termed syncope, but the word is not appropriate, as the heart continued to beat after respiration ceased. This is what should have been anticipated. When death is produced by ether the animal's heart continues to beat long after the arrest of respiration. The pulse is quickened by ether and maintains its force through a long state of anæsthesia. In these facts lies the safety of ether. But it should never be forgotten that there is danger at a certain stage, and the danger is from the side of the respiration, which at length ceases. Stertorous breathing proceeds from paresis of the muscles of the palate, and should lead to the ether being suspended. So respiration growing more and more shallow and less frequent is a warning, and should not be overlooked. It is very rare that the heart fails—perhaps never. Pallor is rare, too, and should excite attention if it occur. But, we repeat, the danger of ether is from the side of respiration, that of chloroform from the heart, and this fact goes far to explain their relative safety. In chloroform narcosis the danger is much more sudden. Ether gives warning.—*The Doctor* (London)

## Original Lectures.

## CLINICAL LECTURE.

By ALFRED L. LOOMIS, M.D.,

PROFESSOR OF PATHOLOGY AND PRACTICAL MEDICINE IN THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF THE CITY OF NEW YORK.

(Reported for THE MEDICAL RECORD.)

## PLEURISY—FIBROUS INDURATION OF THE LUNG—BRONCHIAL DILATATION—BRONCHIAL HEMORRHAGE.

GENTLEMEN:—The case which I shall first present has the following history: The patient, a shoemaker by trade, is 48 years of age; has a good family history, and has always been temperate. Eight years ago he suffered from an attack of pleurisy, which lasted nine weeks, when recovery seemed complete, with the exception of some pain in the side, which gave him some inconvenience, but was not so severe as to prevent him from pursuing his accustomed avocation. Two years ago he began to be troubled with a short cough, and one morning, after a severe fit of coughing, vomited about a pint of blood, but does not recollect whether it was of a dark red or of a bright red color. After vomiting the blood the pain in the side was relieved, but he became more feeble than before, lost flesh and strength, and began to expectorate considerable quantities of whitish "phlegm," especially in the morning. His cough became somewhat paroxysmal, and frequently continued until vomiting occurred, when, for a time, he was relieved. During the last two years he has suffered somewhat from shortness of breath.

*Comments.*—From the history of this case we might be led to infer that this man, nine years ago, suffered from an attack of subacute pleurisy from which he made a fair recovery, but from that date fibrous induration of the lung commenced, and as a consequence contraction of the chest-walls and retraction of lung-tissue has taken place, with probable dilatation of the bronchi upon the affected side. In other words, from the history I should be inclined to regard the case as one of fibrous phthisis; and if it shall prove to be such, upon further examination, it will be especially interesting to us, for we do not often have the opportunity at a college clinic to see cases showing a phthisical development which had its commencement in a pleurisy. I have, however, frequently directed your attention to the fact that there is danger that phthisis may follow subacute pleurisy. Whether our suspicion is correct or not, can only be determined by a

## PHYSICAL EXAMINATION.

From the appearance of the chest I should imagine that some portions of the lungs are emphysematous; there is sufficient of the barrel-like expansion to warrant such a suspicion. Again, you will notice that there is a prominence of the left side as compared with the right, which is due either to bulging of that side or to retraction of the right side, perhaps to the two causes combined.

As the patient takes a full inspiration it will be noticed that the left scapula moves considerably more freely than the right. Anteriorly there is a falling in of the chest-wall in the infra-clavicular region upon the right side, and upon full inspiration there is less motion than in the corresponding region upon the left side. Vocal fremitus is more marked upon the right than upon the left side, and is markedly increased as we reach the upper portion of the right lung.

Emphysematous percussion is distinct over the left

lung, anteriorly and posteriorly, and more marked above than below. There is marked dullness at the upper portion of the right lung, both anteriorly and posteriorly, the percussion note having a "wooden" character, so-called, and indicates a thickening of the pleura, with perhaps fibrous induration of the lung beneath.

There is dullness upon percussion at the lower portion of the lung, but it is much less marked than above.

*Comments.*—The exaggerated resonance upon the left side shows that the left lung is doing the major part of the work in respiration, and the distention has occurred as the result of the increased labor. We have then, in this case, a marked retraction of the chest-wall upon the right side, which indicates pleurisy; but the fact that there is increased vocal fremitus upon the same side tells us of something more than pleurisy, and is evidence of consolidation of lung-tissue—in this case due, probably, to fibrous induration of the lung. If there was pleuritic thickening only, the vocal fremitus would be diminished, whereas with lung consolidation it is increased, and that is the manner in which we step from retraction of the side due to pleurisy, to retraction of the side following consolidation and retraction of the lung.

*On auscultation.*—There is heard in the right infra-clavicular region a tubular breathing, amphoric in quality. Below, there is pure bronchial breathing, with absence of vesicular respiration except at the end of a full inspiration, when it can be heard, but is rude in character. There are no friction-sounds in front, either above or below.

The same sounds are heard behind as in front, and there are no evidences of fluid in the pleural cavity.

Over the left lung, besides the ordinary auscultatory signs of pulmonary emphysema, there is heard a kind of crumpling sound; it is not exactly like a pleuritic friction-sound, but has a peculiar crumpling character, heard at the end of inspiration, and is characteristic of interlobular emphysema. There is a diffused apex-beat, a distinct epigastric pulsation, but no cardiac murmur.

[The auscultatory signs were given by students and corrected or corroborated by the professor.]

*Comments.*—From these physical signs we conclude that this patient has fibrous induration of the lung-tissue at the upper portion of the right lung, with dilated bronchus, and also slight consolidation of lung-tissue throughout the lower portion of the same lung; at least sufficient to give rise to bronchial character of respiration. This man, eight years ago, had a pleurisy, and the result was adhesion of the lung to the chest-wall, and as the result of such adhesion the free play of the lung was interfered with, its expansion was limited, and as the result of that, dilatation of the bronchial tubes has taken place. The dilatation of the bronchi is secondary to the pleurisy and fibrous induration of the pulmonary tissue. Under such circumstances, when undue exercise throws an increased quantity of blood into the lungs, bronchial hemorrhage is quite likely to occur. Such hemorrhages are of rather frequent occurrence, and are due to what Niemeyer has called collateral fluxion; that is, there is more blood thrown into the lungs than can be returned by the other side of the heart, and pulmonary hemorrhage is the result. Under such circumstances hemorrhage from the bronchial membrane is rather the rule than the exception, for the bronchial mucous membrane is very commonly weakened, and often ulcerated, when dilatation of the tube has taken place, and the vessels are liable to give way when there is,

from any cause, an over-accumulation of blood in the lungs.

*Prognosis* in this case is not the worst possible for phthisis; and although recovery is doubtless out of the question, yet it is possible that the patient's condition can be very much improved. If he could be placed in an atmosphere in which he would be obliged to breathe but little, such as is afforded in Colorado, the atmosphere of a high altitude, he would get along very well. These are the cases which are specially benefited by such a change of climate; such a change as a transfer from New York to Colorado will afford. Any treatment further than that will probably benefit him but very little. As a matter of course, it is proper to sustain nutrition, and carry it to the highest possible degree. If he remain here the final result in the case is only a question of time, and when it shall be reached depends materially upon the amount of exposure to which he is subjected, and the condition of his digestive apparatus.

As a matter of routine he may take cod-liver oil if it agrees with him, although it does not usually benefit this class of cases. Arsenic, strychnia, and iron are the remedies upon which I should place most reliance, and believe them to be the most serviceable of any which can be employed. The arsenic is most advantageously combined with iron. I should, however, expect little present benefit unless from a change of climate.

#### CASE II. GASEOUS DISTENTION OF THE STOMACH— CIRRHOSIS OF THE LIVER.

The history of this case is as follows: The patient is 35 years of age, a well-built and powerful man, and complains simply of an uneasy sensation and a sense of fullness in the region of the stomach. He has vomited occasionally, but has never vomited blood, nor has he passed blood by the bowels. He has been addicted to the use of alcoholic drinks for several years; gets drunk occasionally, and takes his liquor "straight." As the abdomen is exposed you will notice while the man is in the standing position that there is a swelling in the region of the stomach. When the patient lies down, however, this distention entirely disappears. No tumor can be felt, there is no dulness upon percussion, but on the contrary there is marked tympanitic resonance over the region of the stomach as well as over the entire abdomen. Percussion over the region of the liver reveals the fact that the arc of normal hepatic dulness is very much diminished.

*Comments.*—The fact that this man has been a drinker of alcohol for a long time, that he has gaseous distention of the stomach and bowels, and that there is marked diminution in the size of the liver, leads us to the conclusion that he has cirrhosis of the liver, and that the symptoms of which he complains are dependent upon gastric catarrh. Such a distention of the stomach and intestines is perhaps the earliest symptoms of cirrhosis of the liver; it appears before vomiting of blood, hemorrhage from the bowels, before any noticeable change in the size of the organ; indeed, before any of the usual symptoms of that affection.

*Treatment.*—The only thing to be done, as far as the liver is concerned, in the way of treatment, is to stop taking alcohol. For the gastric catarrh, after stopping the use of alcohol, it is important to regulate the diet, being careful that only so much food is taken as can be retained, and of such kind as will be least liable to offend the stomach. Such a regulation of diet must be rigidly adhered to if the gastric catarrh is to be controlled. If the patient is willing to submit

to the rigid rules required with reference to diet and abstaining from the use of alcohol, improvement may be expected.

As soon as food can be received without being rejected, there is nothing which is so effectual in correcting this gaseous distention of the stomach and intestines as *nux vomica*. A prescription which I very commonly employ in these cases of rum stomach consists of equal parts of the compound tincture of gentian and columbo, with from five to fifteen drops of the tincture of *nux vomica* in each dose, and taken before meals. An occasional aloeetic and mercurial purge will also be beneficial.

#### VALVULAR LESION OF THE HEART.

The case before us has the following history: The man is thirty years of age, and says that he comes here because he has disease of the heart. When asked why he thinks he has disease of the heart, he replies by saying: "Because he feels a pulsation in the region of the heart;" in other words, he has been conscious of having had a heart during the last twelve years. Twelve years ago, or a little more, he had his first attack of acute articular rheumatism, and was sick in bed three or four months. He has had seven or eight attacks since, and each one has lasted for some time, one continuing for over six months before there was any marked improvement.

The first thing that attracted the patient's attention towards his heart was the palpitation, or "pulsation," and it became so annoying that it interfered with his work. When he turned around quickly a "kind of dizziness" came over him. He has been steadily growing worse with reference to these symptoms, but more particularly during the last two years. Of late there has been increased disturbance of the action of the heart, and he has suffered from vertigo more than usual. He knows of no special reason why his symptoms should have increased particularly during the last two years, unless it was due to the fact of his having had an attack of rheumatism about two years ago. Within this time, however, he has had "chills and fever," and, while sick, his heart troubled him very much, and has continued to trouble him more than before since that attack, especially on going upstairs. He has had swelling of both feet, the œdema, however, extending no higher than the ankles. He has not had any disturbance of the stomach; no disturbance of vision, except transient and in connection with the vertigo; and has never had cough and expectoration. His pulse is regular, and has a slightly jerking character.

*Comments.*—From the history of the case alone, it is quite probable that this man has organic lesion affecting the aortic valves. The reasons for suspecting that condition are, that he has had frequent attacks of vertigo, which rarely accompanies mitral lesion. This symptom almost always accompanies aortic lesion when there is considerable hypertrophy of the left ventricle. Again, he has not had cough and expectoration, a fact which points to aortic rather than mitral lesion. For, a mitral lesion continuing twelve years, without some evidence of bronchitis, would be rare. One good reason for suspecting that it might be a mitral lesion, is the fact that it was developed while young. His pulse is not characteristic of either aortic or mitral disease. So far then as the history can assist us, it favors aortic lesion, and we will now determine by physical examination whether our suspicion is well founded.

*Physical Examination.*—On inspection, it will be seen that his countenance does not indicate a very

great deal of suffering. It will also be noticed that there is an increased area of the apex beat, and that it is carried to the left and as high as the fourth rib; there is also a slight pulsation of the carotids. Upon palpation, it is found that the cardiac impulse is more forcible than normal.

On percussion it is found that the area of normal cardiac dullness is much increased. From the fact that there is an increased area of apex beat, from the fact that it is carried considerably to the left, and that the cardiac impulse is more forcible than normal, and that there is increased area of dullness in the precordial region to the left, we are led to the conclusion that there is hypertrophy of the left heart.

On auscultation, a blowing sound is heard, synchronous with the first sound, has its greatest intensity at the apex, is conveyed to the left, and is heard behind.

A slight murmur is also heard at the base, and is conveyed into the carotids. There is some question, however, as to whether the latter murmur is conveyed from the apex or belongs to a lesion at the aortic valves. It seems to possess a different character from the murmur heard at the apex; and from the additional fact that it is heard in the carotids, I should be inclined to regard it as a murmur indicating organic lesion at the aortic orifice. We have, then, in this case, aortic obstruction and mitral regurgitation. There is also hypertrophy of the left heart, with some dilatation of its cavity. There may also become dilatation of the right ventricle, indicated by the œdema of the feet; but before deciding this point I should wish to examine the patient's urine.

The treatment of this case is for the most part purely hygienic. He should take iron daily. When there is failure of heart-power, as is evidenced by the œdema of the feet, digitalis may be of service. The better treatment in that particular, however, is to prevent failure of heart-power by avoiding everything which calls the heart into active exercise. Life in the country is better for him than life in the city. He should, if possible, live in a climate where there is the least liability of having another attack of rheumatism. For, after one attack of rheumatic endocarditis, every subsequent attack renders the case worse and worse, until finally the heart gets into an unmanageable condition and goes over to complete failure of the right, when there will be no hope of affording permanent, perhaps not even temporary relief.

ON PERCUSSION OF THE BONES.—Prof. Lücke, of Strasburg, makes use of percussion in the diagnosis of affections of the bones, the nature of the osseous lesions being indicated by the character of the percussion note. He has found that in healthy long bones there is a difference in the percussion note over the apophysis and the diaphysis, the sound of the apophysis being sharper. In the same individual, the sounds produced by percussion of corresponding points on the two sides of the body are similar in pitch. Over the callus of recently consolidated fractures and in chronic central osteitis of the apophysis, the percussion sound is duller than normal, while, on the other hand, in chronic arthritis of the knee the sound over the rarefied extremity of the tibia is higher pitched than on the opposite side. The fine differences in the tone are difficult to appreciate, and can be most easily obtained over the bones of the extremities, where there are no subjacent cavities. The extremity should be raised while practising percussion.—*Gazette Médicale de Paris*, June 30th.

### THE TREATMENT OF SPRAINS BY MASSAGE,

WITH A RÉSUMÉ OF ITS RESULTS IN THREE HUNDRED AND EIGHT CASES OF JOINT CONTUSIONS AND DISTORTIONS, OR THEIR SEQUELÆ.

By DOUGLAS GRAHAM, M.D.,

BOSTON, MASS.

"THE physician must be experienced in many things, but assuredly also in *anatripsis*, the art of rubbing up; for things which have the same name have not always the same effects; for rubbing can bind a joint that is too loose, and loosen a joint that is too rigid; . . . and the joint must be moved about, not violently, but so far as it can be done without producing pain."—*Hippocrates*, "Peri Arthron," Littré, vol. iv., page 100 *et seq.*

On the contrary, says Dr. Wharton P. Hood, in his very interesting little book on *Bone Setting, So-called*: "A slight degree of mobility, checked by pain, and accompanied by a spot tender on pressure, is sufficient in the absence of any evidence of acute disease, to justify manipulation having for its object the breaking down of adhesions (page 52). The painful spot being discovered, the limb must be steadied on the proximal and grasped on the distal side of the affected joint, the thumb pressure applied to the seat of pain, and the joint sharply flexed, or flexed and extended, sometimes also abducted or adducted, as the case may be (page 69). In executing these manœuvres the chief thing necessary is for the operator to have the confidence to exert sharply and instantaneously the full leverage given to him by the limbs (page 88). The morbid states that are actually successfully treated in this manner are stiffness and pain of joints, etc., and sprains, whether of recent date or of old standing, but which have been treated by rigidly enforced rest" (page 26).

The following two cases will better illustrate the views of Hippocrates than those of Dr. Hood on this subject. The first should have been an admirable case for the breaking up of adhesions according to the indications, and in the manner just described by Dr. Hood. Nevertheless, the manner and result of the manipulations in this case would, it seems to me, go far to prove that there were no such adhesions about or in the joint as to require such forcible procedure. Although Miss C. was a young lady of good muscular vigor and firm tissues, yet, perhaps, from presuming too much on those very qualities, she had sprained her ankle three times within two years. The last injury was naturally the most serious, the foot turning violently inwards as she alighted on a coil of rope while jumping into a row-boat. For two or three weeks following she was treated with rest, bandages, etc., and after that she got about on crutches, walking stiffly and with pain, and thus she continued for three months without further improvement. Despairing of anything being done, she reluctantly consented to try massage, for she had had ordinary rubbing every day since her accident. About three months after her mishap I was called, and on examination found that there was still considerable effusion in front of the external malleolus and behind the internal, pressure on which excited sharp pain, in the former more than the latter, and to these places was

referred the pain, which was aggravated by passive motion of the foot, and this pain seemed to be the chief symptom in limiting the passive motion to a very slight degree of flexion and extension. Stiffness and weakness of the muscles from the knee downwards, with induration of the cellular tissue, were also marked features of the case. After twenty minutes' malaxation, or kneading with the palm of the hand and fingers, alternating with friction in an upward direction as far as the knee, the effusion was slightly diminished, the tissues were suppler, the limb felt more comfortable, and yielded more readily to passive motion. The patient could now flex and extend the foot herself somewhat, which, before the massage, was almost beyond her power to do. At the second visit I added a little resistance to the voluntary flexion and extension of the foot, but this was almost a make-believe, so feeble were her own efforts in moving it. At the third visit the spots, which had been painful on pressure, could bear vigorous manipulation very comfortably. Henceforth friction, malaxation, passive and acto-passive motion were persisted in half an hour or so daily, and after five massages the patient walked about the house without crutches or any other aid, and did not require the use of them again. After the sixth *massage* she went up and down stairs naturally, and after the eighth walked half a mile, then eight days from the time this treatment was begun. Four more visits were made on alternate days, and at the last one I tied a handkerchief around the metatarso-phalangeal joints (ball of the foot), and to this attached the hook of a spring-balance, the indicator of which was pulled out to 18 lbs. by flexing the foot (contraction of the anterior muscles), which is a severe enough test, as any one can ascertain if they will take the trouble to try. The patient has continued well ever since, and has had no relapse, now over three years.

Much of the immobility of the joint in this case seemed to me to be due to moderate tonic spasm of all the muscles of the leg, and I at once succeeded in convincing the patient that it was to a great extent within her power to cultivate the faculty of *voluntarily* relaxing them, so as not to resist the passive motion, which latter was proceeded with gently and tentatively, not forcibly, and with all the leverage afforded by the foot, but being limited by the slightest approach of pain and involuntary resistance, and thus in three or four days there was gained free movement of the joint.

In marked contrast with the condition of tissues observed in the affected limb of the previous case and the effect of massage upon it, is the flabby, atonic state of muscles and laxity of joint in the following case: Miss A. has been in a nervous, dyspeptic, half-invalid, loose-jointed condition for sixteen years. To pressure (I ought to say to touch), either on the spinous processes or on the muscles on both sides of them, her back is fearfully sensitive. High pressure in school life was said to be the cause of this state of affairs. There was no history of uterine trouble, nor anything of a hysterical nature about the case. For several years she had been growing flat footed, for which shoes of such a make as would preserve the arch of the feet were advised. Nine months before I saw her she was walking along an uneven road, her foot slipped, and in the effort to regain her balance so as to save her back, she made a misstep, twisting her left foot inwards or outwards, she could not tell which. The foot swelled to about one-half more than its normal size, and the pain was referred mainly to the instep. For five weeks the recumbent position

was kept and antiphlogistics used. Her further history to the time I saw her, eight months after, was one of ups and downs, aches and pains. Suffice it to say, that at my first visit I learnt that then a walk of a square would lay her up for a week with pain and weakness in the ankle and instep. She walked with a limp, and going up and down stairs was tedious and painful. When reclining, which was most of the time, the foot had a forlorn aspect, drooping forward and inward, and it admitted of too free passive motion in all directions except that of flexion, to which there was a yielding resistance, and this was felt by the patient as a disagreeable stretching sensation, not only in the calf muscles and those on the posterior aspect of the thigh, but also in the muscles of the back even to the nape of the neck. Along the inner border of the foot pain was said to be constant, and at the articulation of the first metatarsal bone with the cuneiform insertion of the tibialis anticus, there was too much mobility.

From six weeks after the injury to the time I was called she had had at various times three manipulators, non-medical people, who handled the limb as if they were afraid of touching it. There seemed to me to be no necessity for extreme gentleness in this case, as it was very evident the limb was now suffering more from impaired nutrition and innervation consequent upon the necessitated disuse than from anything else; so I at once began by giving it vigorous manipulation or deep rubbing as far as the knee, with brisk passive motion. That such could be done without causing any pain at the time seemed very wonderful to the patient, and no doubt the mental effect of this was good. I then asked the patient to move the foot herself as she was reclining, but it was a pitiful effort, scarcely visible. Nevertheless, I said, "That's first rate. Now move the foot up and down, and I will resist both ways." But this at first was a make-believe, for my so called resisting motion was a simple aiding of the patient's voluntary effort, and no resistance at all. The object was to encourage the effort of the will, which in this condition might be one-half or two-thirds what was necessary to do the required movement. Under these procedures the defective will-power and impaired nutrition improved *pari passu*.

After the first *séance* of twenty minutes it was to be expected that such a hyperæsthetic individual would be quite tired out and much worse generally, as was the case; but I firmly adhered to the theory that the more strength the limb gained the better able would she be to bear her numerous aches, in which she agreed with me. The patient was directed to try to flex and extend the foot a few minutes twice daily when lying down. On the day following the third massage, February 11, 1877, the patient walked without limping any more. From this time onward resisting motion was no longer a make-believe, for it was evident that the limb was gaining strength from day to day, so that after half a dozen visits in eight days she went up and down a long flight of stairs naturally and easily. At the end of ten days, after seven massages, I tied a handkerchief around the ball of the foot (metatarso-phalangeal joints), and put one loop of this over the hook of a spring-balance, the indicator of which was pulled out several times to 12 lbs. by the upward movement or flexion of the foot. The other foot pulled 16 lbs. in the same manner; this one had also been getting a portion of the same treatment, for it too had suffered somewhat from disuse. In the next four weeks half a dozen more massages were administered, and the foot and ankle gradually increased in strength so that she could do anything with the limb that her

general strength or the state of her back would allow, from going upstairs with an elastic step or walking half a mile to utter indisposition to move from the couch. The foot and ankle were no longer the weakest parts which "had to stand the strain," the muscles of the leg were firmer and stronger, and it seemed as if there was more of an arch to each foot, a result which an improved state of tonicity of all the muscles of the leg and foot, but particularly of the tibialis anticus and peroneus tertius, might tend to produce by supplementing any natural or acquired laxity of ligaments.\* Six weeks later the patient wrote to me that "both ankles were certainly stronger than before the accident last spring." †

To Dr. Stoddard, of Northampton, I am indebted for the history of the following case: "Some three months ago I was called to see a young lady who 24 hours previously had made a misstep in descending a flight of stone steps, twisting her right ankle. Considerable pain was experienced in the foot and ankle at the time; but as she was not actually incapacitated for motion, she continued to hobble about until a few hours before my visit, when increasing pain and swelling alarmed her, and my advice was sought. I found the foot and ankle much swollen, and their temperature considerably elevated. When motion of the foot to any extent was practised, she cried out with pain; the power of voluntary motion was much impaired. With some hesitation, for I had not then ventured to employ massage in a case of recent sprain, I suggested a trial of this method. A gentle but thorough manipulation was not only surprisingly well borne, but the patient expressed considerable relief from pain at the close of the operation, the swelling was reduced one-half, and at my request she practised voluntary motion of the foot. To meet the prejudices of the friends a flannel bandage wrung out of arnica-water was applied, and quietude enjoined. At my second visit, 24 hours afterwards, the relief experienced had been maintained, and both temperature and swelling were still further reduced. A second manipulation was as well tolerated, and appeared to be of the same relative value, as the first. Passive motion was practised with but little expression of pain; accordingly moderate voluntary motion was directed. A third application of *massage* two days subsequently secured almost complete subsidence of swelling, the temperature of the parts had become nearly normal, and no pain was experienced on passive motion, so the patient was advised to walk about a little. The flannel bandage had been discontinued after the second day of treatment. The case went on well, and, after two more applications at intervals of two days each, was dismissed. At that time she walked with a scarcely perceptible limp, and complained only of a little weakness of the ankle. These symptoms soon disappeared and a few days later she was walking as well as ever."

Dr. Corey, of Westboro', has very kindly sent me a report of the following case which he also treated with massage: "J. M., young man *æt.* 16, fell from a fence, striking upon the right arm in such a manner as to cause what seemed to be a severe sprain at the elbow-joint. In less than an hour after the injury I saw the arm, when the joint was so much concealed

by the swelling as to make it very difficult to make out the landmarks. I could discover no fracture nor dislocation, but wishing to be certain, I at once went to work to reduce the swelling, so that I might the better learn the condition of the joint. I began massage on the upper border of the swelling, and in about twenty minutes, much to my surprise, the arm was reduced to nearly its natural size, and the joint was easily traced in all its points. I predicted, as is usual with such cases, a lame arm for several weeks; but, upon the second day after, I met the young man carelessly swinging his arm, and on inquiry as to how it was, he answered that he had had no trouble with it since the day of his fall. Now, one of two things: either the condition which caused the swelling was different from that which usually attends such accidents, or the massage restored a natural state of the tissues and prevented the inflammation which so constantly follows."

Mullier\* gives a comparison of the treatment of sprains in the Military Hospital at Namur, from 1871 to 1874. In 1871 and 1872 there were treated 42 sprains with immovable dressings, tight bandages, etc. The average duration of this treatment till recovery was 25.6 days; whilst in 1873 and 1874 there were 37 sprains treated with massage alone, the mean duration of treatment till recovery being nine days. The latter procedure offers important advantages in fractures; and several cases are cited in which the presence of fixed pain, of ecchymosis around and over the external malleolus, of swelling and functional disturbance, would have led to the diagnosis of fracture of the fibula. After a few massages, the uninjured continuity of the bone could be recognized, and a proportionately speedy recovery obtained. In one case, after daily massage for five days, the swelling was so diminished as to reveal the existence of a fracture. (When the swelling is so tedious and difficult of removal, one might reasonably suspect more serious mischief than a sprain alone.—G.)

In the *Allgemeine Medicinische Central Zeitung* for Sept. 4, 1875, is a report, entitled, "*Results of Massage in Joint Contusions and Distortions*," by Dr. Gassner, Military Surgeon, Würzburg. Gassner quotes from Billroth, Volkmann, and Erichsen, to show that, in spite of the most careful and conscientious treatment in the usual manner, even apparently light sprains sometimes lead to secondary consequences. He states that since Dec., 1874, he has made use of massage exclusively in 24 cases of acute serous joint inflammation occasioned by sprains, with the result in every case of speedy and complete cure. Of these 24 cases, there were 9 of the ankle, 7 of the knee, 6 of the wrist, and 2 of the elbow-joint. Most of the patients were strong, robust men, who reached the hospital on the second or third day after the injury, with the contours of the injured joints completely effaced, and the surrounding tissues hot and painful. The presence of bone or of muscular injuries, or of considerable rupture of ligaments, could not be proven in any of these cases. The average duration of the stay in the hospital for all of the 24 cases was 8½ days; for those of the ankle-joint, 9½; for those of the knee, 9 days; for those of the elbow, 9 days; for those of the wrist, 5 days. A chronic case of serous inflammation of the knee-joint after having been in the hospital for 118 days under the usual treatment, then had massage for 24 days, and was ready for military duty. Gassner wishes it to be understood that the duration of the treatment in all these cases

\* Dr. L. Faye, of Christiania, has seen favorable results from massage in relaxation and slackness of joint capsules and ligaments.—Schmidt's *Jahrbuch.*, Bd. 168, page 278.

† In the *New York Medical Journal* for January, 1874, there is an interesting article by Dr. Wm. R. Fisher, on an old, troublesome sprained ankle which was successfully treated by massage, in a comparatively short time.

\* Virchow u. Hirsch's *Jahresbericht*, 1875, vol. II., p. 533.

could be put down as much shorter, if the time were deducted which the patients remained in the hospital after "perfect cure," until they were unequivocally able to do full duty without hindrance. The majority of the patients were free from pain, swelling, and other disagreeable symptoms on the second day of the treatment, some of them were on the first, and all were by the third.

Like favorable results did Gassner obtain in five similar cases also treated by him with massage, outside of the hospital. These cases, says he, convinced him of the real benefit, indeed, almost magical effect, of the massage, which he thinks was materially aided by making the patients use the injured limbs in spite of the pain. It cost him no little doubt as to the propriety of laying aside the dogma of absolute rest.

For the sake of comparison, Gassner places the above-mentioned 30 cases treated by massage against 13 quite analogous cases which were treated by him in the usual manner of rest, immobility, etc., and which also recovered, but only after weeks in place of days. The duration of the stay in the hospital of these 13 cases was on the average 28 days; for 6 cases of the ankle, 22 days; 3 of the knee, 37 days; 3 of the wrist, 30 days; and 1 of the elbow-joint, 28 days. He also mentions two more cases which he treated after the ordinary methods, in which but limited usefulness of the limb resulted, so that after all the patients had to be considered as half-invalids. Only in severe injury of the joints, attended with considerable rupture of capsules, ligaments, or muscles, or harm to the bones, would he make use of immobility by plaster-of-Paris dressing; and after the parts have been kept at rest long enough to allow time for repair, he would then apply massage to get rid of the consequences of the previous immobility. But he would give massage the preference to all other methods in such cases as those he has treated by it; for well he remembers the tardiness of recovery of his own sprained left ankle and contused right knee, in 1862, under the many weeks of regular treatment, followed by months of painfulness and irritability of the joints, and much he regrets not then having had massage.

Dr. G. Berghman,\* of Stockholm, has treated, by means of massage, 145 cases of recent traumatic joint affections not over 8 days old, contusions and distortions with or without effusion, synovitis with serous effusion or effusion of blood into the joint capsule, etc. Of these 145 cases, there were 70 of the ankle, 41 of the knee, 8 of the tarsus, 10 of the wrist, 5 of the elbow-joint, 6 of the fingers, 2 of the acromioclavicular, and 3 of the humero-scapular joints. The ages of the patients varied from 6 to 70 years. (One case 88 years of age is given in detail.) In no case, it is said, did the treatment by massage leave them in the lurch, for there followed always "perfect recovery;" and none of the patients, almost all of whom Berghman saw long after, complained of any trouble worth mentioning. Two sittings were given daily, and of the number necessary till "cure," it was evident from the statistics that these depended on the time when massage began, for recovery was so much the sooner the earlier after the injury this method was put in use. For the 70 cases of the ankle in which massage was used within four days after the injury the average number of sittings was 11.70, time nearly six days till recovery; for other cases of 5-8 days' duration before massage, 19.37 applications, or 9½ days on the average. The knee cases of 4 days'

standing required 10.46 sittings, time occupied 5½ days; those of 5-8 days old, 19.33 massages, or a little over 9½ days on the average. I have been unable to find the statistics in full of these cases, but the summing up is given in the second journal referred to, as follows: 104 cases in which massage was applied within 4 days after injury were "cured" with an average of 12.44 sittings, or in about 6½ days; 41 were treated by massage after 4 and before 9 days had elapsed after receipt of injury and required on the average 17.60 massages, or nearly 9 days till recovery. In order to show that the older the results of such injuries were before this method was used upon them, the longer did it take them to recover, a table has been given of 38 cases in which from 9 days to 3 months had elapsed before massage was begun, and the average number of sittings required was 44.68, or 22½ days.

In traumatic joint affections Berghman finds that the massage has an antiphlogistic and sedative effect, not an irritating one, as was formerly supposed; and that it does not have the disadvantages of other antiphlogistics, whilst it speedily obviates or removes blood-stasis, furthers the absorption and removal of accumulated parenchymatous exudation as well as of the out-wandering white blood-corpuscles, and thus restores the normal relations of pressure in the circulatory system. Clinical histories are amply communicated to show that in severe cases massage afforded relief in an incredibly short time. One or two sittings were usually sufficient in apparently very unfavorable cases to allow the patients active motion of the injured joints, even of the lower extremities. B. considers that the earliest possible use of the injured joints is very useful. Quite a number of these patients were brought before the Society of Swedish Physicians during and after treatment.

It may not be amiss to give a few of Berghman's cases here: A man, *æt.* 26, of unusually large and heavy frame, sprained his ankle so badly that he could not walk. The foot was enormously swollen, the skin around the ankle hot and shining; there was extravasation of blood under the skin, which extended far up the leg, and effusion of blood had taken place into the joint.\* The sensibility to touch over both malleoli was so great that Berghman feared fracture. After one massage of 15 or 20 minutes, the pain was so much decreased that the patient could walk a little. The next day two sittings were held at the house of the patient, and on the third day the patient came to the house of Berghman. On the ninth day the patient could dance. Still, as some swelling and a feeling of stiffness remained, the treatment was kept up for some time longer; and after forty-six massages the patient had no more trouble.

A man, thirty years of age, formerly suffered from traumatic effusion into the left knee-joint, which confined him to bed for eight weeks before he could make any use of the limb. Again, by a fall, the same knee was forcibly bent, and thus injured the second time. Immediately there was severe pain and great swelling in the knee-joint. In spite of the knee being

\* It would seem to be stating it rather too positively in saying that effusion of blood had taken place into the joint. In view of what is known about such an occurrence, *probably it had*; for Billroth says that "when the patient has died of more serious injury and afforded opportunity to examine such lesions we find in a moderately contused joint extravasations of blood in the synovial membrane, and even blood in the cavity of the joint itself; in contusions without fracture the effusions are rarely so extensive that the joint is tensely filled with blood, though this may occur."—Surgical Pathology, p. 214.

† Effusion of blood into the joint is indicated, should swelling of the articulation follow immediately upon the injury, contusion, sprain."—Bryant, page 711.

surrounded with ice, neither did the swelling nor redness abate; and it still remained hot and sensitive. After the first massage the pain all disappeared, and the patient was able to walk without much difficulty. After twelve massages in six days the effusion and all the other annoyances disappeared, and the patient complained no more of pain and weakness in the knee.

The shoulder-joint was considered difficult to manipulate on account of its anatomical peculiarities. The following is certainly a severe and unfavorable enough case to test the merits of any treatment whatsoever. But few men would have sufficient enthusiasm for massage to make use of it in such a case. A man, eighty-eight years of age, by a fall got a contusion of the shoulder-joint. Two hours after the injury, B. found considerable swelling and such exquisite sensitiveness to touch that a proper examination could not be made without chloroform. From the axilla there was felt in the joint capsule a good deal of fluctuation. Luxation was not frequent, but upon rotation of the head of the humerus crepitation was observable, yet this was less than and different from what is usual in fractures, and there was no preternatural mobility; so that B. came to the conclusion there was no fracture, but that the crepitation was due to the churning of blood in the joint. Massage was used, and by its influence the pain was allayed on the following day. Sensitiveness to pressure and incapability of motion remained somewhat longer, for the arm had become extraordinarily swollen, much of this being due to extravasation of blood. After sixty-six massages the patient was so well that only slight difficulty of motion supervened after unusual exertion with the arm, but this disappeared by degrees under the use of gymnastics (!). A similar case of injury to the shoulder-joint in a man forty-eight years of age follows, in which, after thirty massages with gradually increasing passive motion, the effusion, swelling, and pain had subsided, and the arm moved well, though still somewhat weak. "Perfect cure" resulted under continued exercise.

"If previously," says Berghman, "a plaster-of-Paris dressing has been applied, even if but for a short time, then there is no prospect of speedy cure by means of massage. The dressing, to be sure, exercises pressure upon the swollen tissues and diminishes the edema in part, but not altogether; the injured limb is kept motionless, the connective tissue proliferates, and soon assumes a plank-like hardness."

Though this *matted, board-like* condition of the areolar tissue was a very marked feature in a case of old sprained ankle, which as a last resort of the therapeutics of despair, had had a plaster-of-Paris dressing applied for six weeks, which had been just left off before recourse was had to massage, yet having had but two massages in one week the patient began to walk the following week without crutches, and two weeks later walked well. As it was with the utmost difficulty that this patient could have any massage at all, I extended each of the two sittings to three-quarters of an hour, and it was very interesting to observe, every few minutes, the suppleness of tissue that was manifestly being gained. For several weeks at first the sprain was regarded as of no account, and the patient limped about, but gradually it became worse, and for more than a year the patient had used crutches, except when at rest.

Dr. F. W. Westerlund,\* of Helsingfors, has treated cases of acute traumatic joint affections by massage

with like favorable results to those of Berghman. As illustrations, six of his cases are given: One, a sprain of the metacarpo-phalangeal joint of the middle finger, with pain, swelling, and impossibility of motion, was well after four massages in three days. The second, an acute traumatic synovitis of the ankle-joint, was restored to its normal condition after six sittings. The third, a case of severe contusion of the right foot, with fluctuation in the ankle-joint and great suppuration of blood under the malleoli, was no better for five days' rest alone, but after eight massages was well, and could walk a mile and a half. The fourth, a contusion of the knee, in a child five years of age, was able to walk without hindrance after three massages, and, after five, swelling and sensitiveness were no longer present. The fifth and sixth, sprains, with redness and swelling, said to be well in three days, after six massages each.

M. Panas (*Journal de Médecine et de Chirurgie*, vol. 43) has treated twenty-three cases of sprain, of which there were twenty of the foot and three of the wrist. Of the twenty of the foot there were twelve of the left and eight of the right. The treatment consisted invariably in the use of massage combined with compression with a roller bandage, alone or with the interposition of wadding. Cure has been the rule in a space of time comparatively short, viz., from the fourth to the seventh day after the accident.

M. Fontaine (*Allgemeine Med. Central-Zeitung*, Oct. 3, 1874) says he has used massage in a number of sprains with extraordinary favorable results. One was attended with laceration of the tendon of the plantaris muscle, another was a sprained hand and thumb, besides about a dozen cases of *distorsio pedis*, mostly light ones, only two being of the severer kind. Recovery resulted in a comparatively short time, the duration of the treatment on the average being from four to nine days, and for the more severe cases from fifteen to twenty days.

In a monograph, entitled "*Du Traitement de l'Entorse par le Massage*," by Dr. F. Rizet, *Médecin Major*, published at Arras, the details are given of fifteen cases of sprains in which massage was employed with results so surprisingly speedy and favorable to M. Rizet, that he would not allow the patients to make use of their injured joints as soon as they desired. The average length of time (probably too short) for the recovery of all being set down at three days, for the knee and ankle four and two-thirds days. Of these fifteen cases, twelve were recent and three were chronic. Of the recent cases four were sprains of the finger-joints, with pain, heat, swelling, and impeded function, which were treated with two or three massages daily, and got well in from two to three days after the injury; six were sprains of the ankle, all of which showed marked improvement by the second day of massage; one of the knee, in which the swelling and redness ceased by the third day, the pain not till the fifth, and the patient was discharged as well and able for military duty on the seventh day after the injury; and one of the wrist, which got well in four days.

The sprains called chronic were from seven weeks' to three months' duration; two were of the wrist and one of the foot, and they are said to have done as well under *massage* as the recent ones, notwithstanding the experience of others that such cases usually take longer. The following seem to be two of his most severe cases:

N., sergeant, fell the 1st of January on the stairs of the barracks, the left foot in the fall being turned outwards so that the entire weight of the body came

\* Schmidt's Jahrb., Bd. 173, page 173.

upon the internal border of this organ. At once there followed pain of the most lively character, great swelling, which concealed the two malleoli, ecchymosis upon the dorsum and internal lateral surface of the foot, absolute impossibility to place the foot upon the ground, and two or three successive syncopes. The evening of the accident there was practised a *séance* of massage of half an hour, which so relieved the patient as to allow him to place his foot upon the floor; the swelling was sensibly diminished, so that the malleoli could be distinguished, which till then were confounded in the general puffiness. If the patient had been allowed he would immediately have left the infirmary, whither he had been transported after his fall, but his entreaties were in vain. Next day two massages, and applications of cold water were continued, which had been used immediately after the accident, before we had seen him. The two nights following his injury the patient rested well, and on the third day after the accident movements were given to the articulation which did not occasion any suffering. During the following few days there only remained slight swelling, and the patient was allowed to leave the infirmary on the 8th of January—seven days after the mishap. He had no more trouble of any kind from the joint.

M., sapper, *et.* 23, on the 27th of June, in attempting at a running jump to go over a wide ditch, failed to reach the summit upon the further side, and fell upon the escarpment, severely spraining both ankles. Deided pain at once set in, and swelling soon was very great on the dorsal aspect of the left foot, and on the external lateral surface of the right; the intermalleolar spaces of both ankles were completely filled up, and it was absolutely impossible for the patient to stand. At his entrance into the infirmary, the same day, a massage of nearly an hour's duration was given, which was borne with much pain. Compresses soaked in lead-water were applied. June 28th, patient passed a comfortable night; diminution of restraint of movement; three more massages and gentle passive motion given to the feet. By the upward pressure, made slowly and gradually with the palm of the hand, the effused liquids are repelled from around the ankles and out of the grooves on each side of the tendo-Achillis towards the superior parts. This day the patient began to stand on his feet, and wished to walk, so much did he feel relieved. Lead-water was suspended and massage alone continued. On the 29th the right foot seemed well and the left evinced but one painful point. On the 29th there was more swelling, and pain reappeared on passive motion of the articulations; redness disappeared. In the evening the feet pressed but slight swelling, and the patient felt well. Massage was continued till the 8th of July, and then suspended, but the patient was not allowed to depart until five days later, on account of the weakness which he experienced in walking.

If in some of our recent sprains, says Rizet, we still have had recourse to cold water or *résolutifs*, it must be avowed it was more the force of habit than of reason which dictated this precept to us, and which, with this mode of treatment, we regard as entirely useless, for in a very short time the massage relieves the pain better than cold water. The duration of the pain at first occasioned by the massage he has found to vary from five minutes to half an hour; the pain of the injury from two to five days under massage treatment. He expresses his appreciation of the value of massage in sprains in the following manner: "Struck by the words of Baudens at the Academy of Sciences, that 'of 78 amputations of the leg or of

the foot, 60 had sprains for their origin,' it was with eagerness we seized opportunities to experiment with a means which, far from deceiving us, has given unlooked for success. They have strongly shaken the faith we had in the therapeutics preconceived by our predecessors and our masters, in forcing us to recognize that the application of immovable bandages in acute sprains has been the most powerful cause of the deplorable effects disclosed by the venerable surgeon-in-chief of Val-de-Grace."

It seems to me that Rizet must have inflicted more pain than was necessary upon his patients, for he states that he began the massage at once over the tumefied and painful places, though gently, and not as most of the others here mentioned seem to have done, and I think as one would naturally do who understood the effects of massage: first, centripetal and circular rubbing at some distance above the injured parts, which can be gradually approached as the soothing effects of this procedure manifest themselves; then alternating with the friction, *pétrissage*, kneading or manipulation, which can also be gradually increased in force and approach the painful spots as its anæsthetic allow; and thirdly, passive motion, which, besides its therapeutic effects in aiding the before-mentioned manœuvres in promoting absorption and preventing blood-stasis and the formation of adhesions, also shows by its degree of toleration what improvement is being gained; and lastly, if the case be a chronic one, varying these procedures with acto-passive or resisting motion.

Thus far I have given but a brief résumé of some of the more recent results of massage in sprains. A copious bibliography of this subject can yet be found in the last edition of the *Nouveau Dictionnaire de Médecine et de Chirurgie*, which lack of space forbids inserting here. And now I may as well sum up what has already been given, for I can find no different or adverse testimony about the matter, and if any one else can I hope they will publish it forthwith. With the exception of the first four cases and my one with the matted, board-like condition of the areolar tissue, we have, then, the results of massage by seven independent observers, whose cases of joint contusions and distortions, sprains or their sequela, thus treated, amount in all to 308, of all grades of severity, of which the average length of time till recovery is 9.1 days. This time would be much less if the 39 cases were omitted in which massage was not begun until from ten days to three months had elapsed after the injury, "in many of which," says Berghman, "other methods of treatment had failed," and which required, on the average, about three weeks' massage till recovery. Of the 55 cases treated by the usual method, the average length of time till recovery was 26½ days, or nearly three times as long as similar cases required by massage. The advantages of massage, then, in such cases would seem to be more speedy relief from pain and swelling, and earlier and more perfect use of the injured joints than by any other method.\*

It requires a good deal of patience, tact, and delicacy of touch in order to gradually approach swollen and painful tissues so as to be allowed to make pressure and movement upon them; and the busy prac-

\* Since writing the above, Dr. T. A. Foster, of Portland, Me., has told me that he thinks there are but few physicians who are aware of the value of massage in sprains. He has used it himself in very severe recent cases, with great or complete relief from pain at the first sitting, and he finds that he can allow his patients the use of the injured joints much earlier than he formerly dared to do under classical treatment. Yet if a case of this kind should come into court he very much doubts if such treatment would not be regarded by the profession at large as malpractice.

itioner, in his haste to get the patient well, is apt to overdo the matter at the very commencement of it. Manual dexterity acquired by constant practice—other things being equal—is the secret of success of operative procedures of all kinds, as well as of the art of applying massage. Incident to all occupations are found anatomical peculiarities of structure largely acquired, and so we find the hand of the *masseur* large and muscular, but soft and delicate, the finger pulps greatly developed with a delicacy of touch that can usually detect the tender spots when there is no external evidence of them, and before the patient has told or shown by reflex action where they are.

## Progress of Medical Science.

**DISEASE OF THE ANTERIOR CORNUA.**—At the meeting of the *Société de Biologie*, of Paris, in March, M. Raymond presented a marble-worker, 49 years of age, who had received at the age of four years an extensive burn of the left arm. The hand is at present a deformed stump. In consequence of excessive use of the right arm the right hand became paralyzed without pain or tingling, and subsequently atrophied. M. Vulpian expressed the opinion, that the paralysis was due to a lesion of the anterior cornua, caused by the irritation induced by increased use of the arm. He recalled a case he had seen in consultation with M. Chareot, that of a tanner, aged 20 years, who was afflicted with infantile paralysis of the left arm, and in whom the right arm became atrophied in consequence of excessive work. He also referred to the case of a soldier, who was wounded in the outer part of the leg, at Reichsoffen, and who was attacked two years later by violent sciatic pains, followed by almost complete atrophy of the entire limb.—*Lyon Medical*, May 27th.

**ENDOCARDITIS BLENNORRHOICA.**—In a paper published in the *Archives Générales*, Dr. Marty gives the history of a case of gonorrhœa in a man 22 years of age, which was complicated by acute endocarditis located at the aortic valves. The principal symptoms were initial chill, fever (104° F.), systolic murmur over the aortic valves, palpitation of the heart and precordial oppression. There was no rheumatism or metastatic articular affection.

Dr. Marty has collected nine other cases from the French literature, in which a disease of the heart or of the pericardium developed itself four or five weeks after the commencement of a gonorrhœa. Of the ten cases (including the above), seven were endocarditis and three pericarditis. Of the former, the affection was located four times at the aortic valves, and three times at the mitral valves. In eight of the cases the cardiac affection was preceded by gonorrhœal rheumatism; in the other two cases there was no articular affection. The complication was sometimes ushered in by a chill, and frequently coincided with a cessation of the discharge from the urethra; in other respects its course did not vary from that of the ordinary form of endocarditis. The frequency with which the affection was located at the aortic valves was noticeable, the converse being the case in acute articular rheumatism. The case reported above ran a favorable course; the patient left the hospital with a systolic, aortic murmur, but without demonstrable enlargement of the heart. The urethral discharge was re-established when the acute symptoms disappeared.

Dr. Marty concludes his paper with the assertion

that any serous membrane may be attacked by inflammation during the existence of a gonorrhœa, and that this inflammation is consecutive to the primary disease of the urethra.—*Allg. Med. Central-Zeitung*, June 2d.

**ON THE NATURE AND SIGNIFICATION OF THE SMALL RED BLOOD-GLOBULES.**—M. Hayem, in a note addressed to the *Académie des Sciences*, states that his physiological and clinical investigations have convinced him that the so-called microcytes, which are described by some observers as specific elements, are simply small red globules modified by external agencies. They do not pre-exist in the blood, and their number varies according to the way in which the preparation has been made. The smallest elements that can be recognized as possessing the character of the red globules measure only two-thousandths of a millimetre. Despite their exiguity they are perfectly disk-shaped and biconcave, but they are sometimes lighter in color than the larger globules. In pathological conditions these globules may lose their disk-shape, but the biconcave form is always retained. The so-called microcytes are spherical in form, some being strongly refractive and dark, and others pale in color; the former appear to be red globules in a sort of tetanic condition, for certain reagents, in destroying them, restore their normal biconcave form. The latter are the more tender elements, which offer less resistance than the others to the effects of endosmosis. The small globules are liable to undergo these changes of form in the normal as well as the pathological state, but certain morbid conditions render the transformation more easy. When blood containing a certain proportion of these globules is examined in the moist chamber, many of them may in fact be seen to assume a spherical, vesiculate, and sometimes even a mulberry form.

The blood of the healthy adult very rarely contains small and dwarf globules, but the blood of the newborn child and of the menstruating woman always contains them. In pathological conditions they are often met with, as after hemorrhages, at the commencement of convalescence after acute diseases, and in chronic anemia of moderate intensity.

The small red globules are found both in the normal and the pathological state, whenever an active production of new elements is taking place; they characterize blood in process of evolution or reparation. From this M. Hayem concludes that they are young, incompletely developed globules, differing from the adult globules only in their exiguity and the facility with which some of them become spherical when removed from the vessels. In organisms which present the conditions necessary for their normal evolution, they are only found in the blood at times when they are formed in large numbers (first weeks of life, menstrual period), and are then never very abundant. In pathological states, on the other hand, when they do not meet with the conditions necessary for their normal evolution, they remain small and accumulate in the blood, so that they sometimes become exceedingly abundant. This is doubtless the reason why the small globules are met with in such abundance in the blood of some anæmic persons; many young globules are formed, but they do not attain their normal development.—*Gazette Médicale de Paris*, June 16th.

**DIPHTHERIA.**—From a recent discussion before the Therapeutical Society of Paris we learn that our materia medica contains only doubtful resources against diphtheria.

# THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, August 11, 1877.

## ADVERTISING PORTRAITS.

It would seem that medical advertising in one of the necessities of the times, so prevalent is it, and so much is it on the increase. With a certain class we are never astonished at any amount of advertising. Whenever the latter is going on, no matter in what shape, these men are expected to be in the front. As no one is to blame, the modest men get tired of guessing at the remarkable coincidences in the law of accidents, and simply view them as matters of course. But it is not our purpose to repeat the old story regarding these chronic and constitutional offenders, as the majority of them are beyond hope of reform, but we wish to call attention to the reprehensible practices of some professional men of standing and of reputation. In the sharp competition for business and in the crowded state of the profession it appears that extraordinary means must be used occasionally to make success reasonably certain. With these men medicine is a business, and must be managed as such. Consequently no opportunities must be neglected for securing pecuniary prosperity. Judicious advertising is such a recognized foundation for this success that it is hazardous to neglect any chance which may offer itself. Hence we are hardly surprised at any manœuvre which has the required end in view. In this connection we will take occasion to refer to a somewhat novel method of gaining public notoriety.

There is being published in this State a cyclopaedia or gazette of useful information, in which are contained the lives and exploits of distinguished men of all callings and professions. No one can deny that there are in our ranks men who can grace any page in history of scientific achievements, and it is proper to say that they should have a fair show. There is no objection to the history of any man's life being written before he dies. If it serves no other useful purpose, it furnishes reliable data for obituary notices. We contend, however, that there is a way of publishing these auto-

biographies in which ordinary modesty and good taste are not offended. But a step has been taken so far beyond the ordinary proprieties that we allude to it with pain and mortification. The publishers of the volume in question have hit upon a rare business expedient in forestalling the success of their undertaking. It is a simple appeal to the personal vanity of certain individuals for a certain sum of money. Besides a flattering notice of the subject of a sketch, a fine steel portrait is executed of him and inserted in the body of the work for a sum ranging from two to three hundred dollars. If this is not a deliberate, paid advertisement of any person whose portrait so appears, we are at a loss what to call it. No matter how worthy any man may be, if he is not able or willing to pay the required sum for the engraving, he is, in the public eye at least, not a distinguished person. It may be hard to believe that some of our medical men, who have earned good reputations for themselves, and who hold professional places of honor and trust, have stooped to such a bad species of taste, but such is the fact nevertheless. And after all, does it not prove the injustice of voluntary advertising in the fact that it must always be a question of money rather than merit? As in advertising in any business the longest purse must tell, certainly the round sum for the portrait settles the question of preference for the one who pays. As an encouraging offset, however, to this miserable business we know of many gentlemen who have declined to become parties to such frauds upon the profession and the public, and whose portraits will consequently not appear in the forthcoming work.

## THE PROVIDENT DISPENSARY PLAN.

THE attempt to establish the medical provident system seems to have been a failure; at least nothing thus far has been done by the committee having the matter in charge. We have had the meetings, the reports, the speeches, and the resolutions, and now the matters. In the meantime the abuses of medical charity are, if anything, increasing in extent, the dispensary classes are more than ever crowded with applicant for relief, and the institutions themselves are appealing to the charitable for aid to carry on their work. The promises for reform which were held out by the advocates of the provident plan have vanished into the emptiness of deferred hope. Even the out-door department of the New York Hospital, which should have been brought to some account, still sells gratuitous medical services for a dollar a month to any one who applies, and many young practitioners must either underbid the wholesale price or prepare themselves to enter some other business.

## THE AMERICAN PUBLIC HEALTH ASSOCIATION.

THE coming meeting of the American Public Health Association will doubtless be equal to the most sa-

guine expectations of all who are interested in its success. Judging from the programme which has been sent to us, the topics discussed will be sufficiently numerous and varied to command the attention of scientists, humanitarians, economists, sanitarians, and physicians. Looking back five years ago, when this Association was first organized, it is hard to believe that so much valuable work has been done. In fact, its remarkable success has proved what can be done by a handful of competent and earnest workers in a great cause. Probably no association of its size or kind can command a more extended hearing through the press, and is more capable of exciting a greater influence for good with the public. If it were necessary to ask its support by the profession, we should do so most heartily. But already by its faithful work it has commended itself to respectful countenance, not only of the entire medical profession, but of learned men in every calling.

## Reports of Societies.

### OHIO STATE MEDICAL SOCIETY.

*Thirty-second Annual Meeting.*

FIRST DAY AT PUT-IN-BAY.

(Special Report for MEDICAL RECORD.)

THE Society met at 2 o'clock P.M., June 12th, and was called to order by Dr. T. W. Gordon, first Vice-President, in the absence of the retiring President, who introduced President-elect, Dr. W. J. Scott. Dr. Scott thanked the Society for the honor conferred by being invited to the responsible position he was called to occupy.

The Executive Committee reported the regular order of business, and fixed the hour of meeting at 9 o'clock A.M. daily.

#### SULPHATE OF QUININE AND FEVER HEAT.

DR. T. W. GORDON then read an able paper on the use of "Sulphate of Quinine in Controlling Fever Heat." This paper was discussed at length. The prevailing opinion seemed to be that when fifteen to twenty grain doses of quinine were given, the extreme fever heat was susceptible of being controlled. Some thought the same result could be reached by giving moderate doses of from three to five grains.

After some miscellaneous business was transacted, the Committee on Obituaries reported the death of the following members: A. B. Jones, Portsmouth; J. S. Bailey, Freeport; Alex. McBride, Berea; S. H. Farrington, Ashtabula; E. Thorn, Yellow Springs; Stephen Benner, Cincinnati.

DR. POOLEY, of Columbus, read a memorial upon the death of Dr. William Awl, in which the services of Dr. Awl as a surgeon and philanthropist were forcibly depicted.

DR. JONES spoke in feeling terms of the character and services of Dr. Awl.

The Society adjourned until 8 o'clock P.M., when DR. POOLEY, Professor of Surgery in Starling Medical College, delivered an interesting lecture on the art of surgery. The Doctor traced its rise and progress from the time of Hippocrates to the present. He showed conclusively that American surgeons are not inferior

to the best in the world, and that to them surgery is indebted for some of the best operations known to the art.

### SECOND DAY.

#### MILK SICKNESS.

The Society was called to order on the second day by the President. Minutes read and approved. After miscellaneous business, DR. S. S. GRAY read a paper entitled "Milk Sickness." His deductions were that this disease is the result of the consumption of some noxious plant that is only found in some uncultivated fields, by various animals, and thence communicated to the carnivorous and omnivorous species.

DR. POOLEY thought it possible the disease was caused by the development of a peculiar fungus.

DR. FORBES, of Toledo, read a paper in which he treated of Reed's method of reducing dislocations by manipulation, citing numerous cases which occurred in his own practice of dislocations of the hips, shoulder, and wrist. With an assistant Dr. F. illustrated the manner of reducing a supposed dislocation of the wrist of one of the members. A lengthy discussion of this paper was had, taking a wide range.

DR. DUNLAP, of Springfield, read a paper on "Fibroid Tumors of the Uterus." This paper was met with many manifestations of interest and appreciation at the hands of the Society, and was warmly discussed by Drs. Reamy, Dunlap, and others.

#### ELECTION OF OFFICERS.

Election of officers resulted as follows: *President*, Dr. W. H. Phillips, Kenton, O.; *Vice-Presidents*, Drs. Forbes, Muscroft, Hubbard, Reed, A.M.; *Treasurer*, S. S. Gray; *Recording Secretary*, J. W. Hallock; *Assist. Secretary*, J. F. Baldwin.

#### PRESIDENT'S ADDRESS.

The President then read his address, the subject being the necessity of greater preliminary instruction for the medical student before entering upon his studies proper, and before commencing the study of medicine.

A committee of five was appointed to consider and report at the next regular meeting on the subject of the President's address.

#### THE PRESENTATION OF PAPERS.

DR. SCOTT introduced the following: *Resolved*, That the author of any paper to be read before the annual meeting of the Society must send its title six weeks in advance to the Secretary; and that he shall send a printed notice of all such papers to every member of the Society one month previous to its annual meeting. Volunteer papers shall be read after the regular papers have been disposed of. Carried.

DR. S. C. AYERS read a paper on "Paracentesis of the Cornea," which was favorably commented upon by Drs. Scott and Noyes.

DR. POOLEY read a paper entitled, "Surgical Treatment of Perityphlitic Abscess."

### THIRD DAY.

#### PREVENTION OF SYPHILIS.

After reading the minutes of the previous day, and attending to some miscellaneous business, DR. MUSCROFT read a voluntary paper on "The Prevention of the Spread of Syphilis." This paper was warmly discussed, some thinking we had all the laws necessary to control the spread of this disease, so far as it could

be controlled; others that we needed stringent laws, etc., etc. Paper referred to Publication Committee.

DR. MORRIS read a paper on the "Use of Hydrate of Chloral in Puerperal Convulsions." The time growing short this paper was not discussed, but referred to proper committee.

#### EXPERT TESTIMONY.

DR. PHILLIPS offered the following resolutions:

*Whereas*, It has become a very prevalent custom, throughout the several counties of the State of Ohio, to subpoena physicians and surgeons to give testimony as experts in courts of law; and

*Whereas*, There does not appear to be any provision upon our statute books to make proper compensation for such services; therefore

*Resolved*, That we hold that our professional opinions are our own, often obtained by great labor and expense, and if considered of value to the State as to parties in civil actions, ought to be paid for. 2d. That a committee of — be appointed to the Society to memorialize the Legislature of this State to enact some statutory provisions to correct this evil, and do justice to the medical profession upon this subject.

The discussion of these resolutions evinced the fact that it would be better to modify the second resolution so that it read as follows:

"That a committee of three be appointed to investigate and obtain the legal facts pertaining to the subject, and report at the next meeting of the Society, and recommend a plan of action."

DR. POOLEY offered the following, which was adopted:

*Resolved*, That the committee of three already appointed to inquire into the rights of expert witnesses be instructed to report, at the next meeting of this Society, a draft of a bill for approval for the protection of physicians in suits for malpractice.

After some further miscellaneous business the Society adjourned to meet at Columbus, Tuesday, May 20, 1878, at 2 o'clock p.m.

This meeting of the Society will long be remembered as a laborious one. Besides the many warm and interesting discussions had on the various reports and papers, a vast amount of miscellaneous business was transacted, and all went away feeling they had profited by being present.

#### ASSOCIATION OF THE PHYSICIANS FOR IDIOTS.

THE Association of Medical Officers of the American Institutions for Idiots met this year at Columbus, in the Ohio State School for Idiots. There, amidst 340 pupils, who were often visited, or brought in the council chamber in support of theories advanced during the discussion, the members held a protracted meeting of four days, in which rose questions of great interest.

DR. EDWARD SEGUIN, President of the Association, read a paper on

##### THREE VARIETIES OF SENSORIAL IDIOCY;

that is, of idioey in which the arrest of mental development is due to imperfections of the nerves and ganglia transmitters of impressions, rather than to the paucity of convulsions or other alterations of the hemispheres.

DR. H. B. WILBUR, Superintendent of the mother institution of this country, read a paper on

##### GENERAL CLASSIFICATION OF IDIOTS,

the value of which was enhanced by the comparison

of his ideas with those developed in the work of Dr. William W. Ireland, Superintendent of the Larbert Scottish Institution for Idiots—a volume which contains, among many matters of interest, the classification of this learned observer.

There was something like piquancy in the presentation by Madam Brown (of the private institution of Barre, Mass.) of a paper on the influence of the unhappy impressions of a mother upon her child during pregnancy and lactation, just after her husband, Dr. George Brown (of the same establishment) had read another on the influence of heredity in the production of idioey. The same ground was viewed from a feminine and masculine standpoint. Both writers, traversing an almost untrodden field of etiology, brought out the points mere familiar to them; the man, those which his mind could trace; the woman, those which touch her great sympathetic; an operation defined by men—who perhaps do not know better—as reflex action; a definition which shows already signs of decadence, by being served up *à toutes sauces*.

The great interest of the meeting was concentrated on the paper of DR. ISAAC KERLIN, on

##### THE ORGANIZATION OF INSTITUTIONS FOR IDIOTS.

It will appear to better advantage in print than when cut up in shreds by the teeth of discussion. It is to be approved without reserve as the expression of Dr. K.'s experience in organizing the Pennsylvania Training-School for Idiots; but it could not have been accepted as the expression of the experience of other older or younger organizers. These creators of institutions for idiots in this country did not find the wants of all the States alike in this respect, nor the mind of the people prepared to accept this uniformity of organization. The majority believed that this uniformity can be reached only through many more experiments. They point out the grievous fault committed by different public charities, and cast in incorrigible forms and structures immature ideas which too soon become dwarfed and crippled; and they want to spare this shame to the young and vigorous undertaking of improving idiots.

Through all these objections, the paper of the vigorous manager of the school of Media, though denied the honor of representing the views of the Association as a whole, has been accepted, and will be published in the *Transactions* of the Society, where it will take for this country the place occupied in England by the *Agenda* of Sir Charles Trevelyan. It will remain the basis of the coming discussion of the great questions, hitherto latent, regarding charitable asylums for children born maimed in their mind. In this direction alone the physicians for idiots can render great services. In the scientific direction their work is far more promising than that of the alienists. The physician for idiots will soon be conceded the right to study the concordance of the native deficiencies of structure with the native deficiencies of function which he has had opportunities to record; whereas the alienist too often finds behind the crazied functions no organic alterations, or such ones as may be results, not causes, of the *mens deuenus*.

The Ohio State institution realizes the latest improvements in buildings, teaching, training, and husbandry. The hospitality of Madam Doren was earnest and profuse, at the same time that the children had an abundant food, and milk three times a day. For that service alone sixty cows are kept; the rest of the farming on the Scioto bottom is on the same scale.

The next meeting of the physicians for idiots will be held in the institution of Syracuse, about the time

of the meeting of the American Medical Association at Buffalo. The members of this Association are cordially invited to the meeting of Syracuse.

E. S.

## Correspondence.

### THE SUCCESSFUL TREATMENT OF HAY FEVER.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—A gentleman from Chicago recently consulted me for what he had supposed to be a persistent cold, but which was really a pretty severe case of hay fever, with the usual signs, sneezing under the provocation of dust, brimstone, matches, and so forth, itching of the nose and eyes, cough, and asthma. He had been troubled for several years, and some years he appeared to have all three forms: the early form, or rose cold; the middle form, or July cold, as I have designated it; and the later form, or autumnal catarrh. Thus he was a sufferer, more or less, for six months out of the twelve. He seriously thought of changing his place of residence to some part of the world where hay fever does not exist, and asked me where he should go. I told him that I believed he could fight it out on this line.

He remained in New York two weeks, transacting some business, and took the treatment I suggested, which consisted in:

1. Central galvanization.
2. A mixture of Fowler's solution and nux vomica, internally (3-5 drops to 10 or 15 drops).
3. The inhalation of a mixture of equal parts of camphor, carbolic acid, and chloroform.
4. Gin and glycerine at night for the asthma and cough.

This plan of treatment is based on the nerve theory of hay fever, and the result so far forth confirms the theory.

The central galvanization gave, as it always or almost always does, immediate relief. The nasal symptoms were quickly helped by the carbolic mixture, the asthma and cough by the gin and glycerine. I should say that I used experimentally, and for the sake of instruction, several other remedies. The spray of bromide of ammonium, as suggested by Dr. Seguin, gave relief, as it usually does, to the throat symptoms. A mixture of chloral and bromide of potassium and ammonium gave relief at night for a number of hours, and is a good suggestion when needed; it also relieves other distressing symptoms of hay fever. The chloral should be used in small doses. Nitrite of amyl gives quick but brief relief in the asthma. On the whole, it has disappointed me in hay fever and asthma.

This patient, whose sufferings had been very great, rapidly recovered. That his recovery was not due to an interval in the disease alone is clear from the fact that the effect of the remedies was felt at once. I advise him to continue the Fowler's solution and nux vomica combination for the present, to provide against relapse or the appearance of the later form in August.

I mention this case as a test and illustration, rather than as an argument. It would be contrary to all my own teachings in regard to hay fever to claim that all cases should be treated alike, or that any specific can be found for it. But the same general principle of treatment—tonics and sedatives—applies to all cases. None of the remedies to be used are painful: none even

disagreeable. The treatment of hay fever should be pleasant treatment; the time for starvation and caustics and cruel injections has passed by. The overthrow of the parasitic and germ theories of the disease revolutionizes the treatment. Judging from my personal observations, and from correspondence with physicians and sufferers in all parts of the country, I should say that we can now do as much for hay fever as for chills and fever. Electricity alone has broken up attacks; so has arsenic, nux vomica, and Turkish baths.

Under the most successful treatment, there will probably be a tendency to revival of the symptoms under exposure to the worst irritants, such as smoke, dust, cinders; but chills and fever also recurs when the poison is constantly entering the system, even though kept down by quinine and arsenic.

Those who can leave home during the attack, and desire to do so, will find Bethlehem, White Mountains, the best and most attractive relief region for hay fever in the country. Next in order come the Adirondacks, and Marquette, Michigan. Fire Island is the best sea-coast place, but the seaside everywhere is untrustworthy; even on the Isles of Shoals the land breezes bring trouble.

### DILATABILITY OF THE URETHRA.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—There has been much discussion of late with regard to the degree of dilatability of the urethra. In all this the histological characteristics are not once referred to.

That the urethra is wonderfully dilatable it seems to us preposterous to deny; and yet we hear at the last meeting of the American Medical Association that this point was actually called in question by some whose experience must certainly have been at variance with the views they have expressed.

There are really two divisions to the mucous coat of the urethra, an inner and an outer one, called, as we believe, by Heule, respectively, *tunica mucosa* and *tunica submucosa*. The *tunica mucosa* is about 0.13 mm. thick; the *tunica submucosa* about 0.65 mm. Now, this mucous coat proper has developed in it numerous papillae which project into the epithelium. In the tissue of which these papillae are the prolongations we find interspersed a large number of cells, similar to lymph-corpuscles; and in some of Prof. Heule's preparations (at Göttingen) we have remarked that this infiltration is so extreme that the mucous tissue consists only of a delicate network, which is completely filled with cellular bodies, which Prof. Heule, if we remember correctly, denominated *agglomerations of gland substance*; and there can in such cases be observed no distinct line of separation between the cells of the tunic and those of the deeper epithelial layer. All conglomerate tissue is highly distensible; and if there were no actual demonstration of the fact, the dilatability of this coat would be sufficiently established upon an *a priori* basis.

As to the other coat, the *tunica submucosa*, it is nothing more nor less than cavernous tissue formed of a stout venous network. There are also two layers, an outer and an inner one, to the muscular sheath; the former longitudinal, the latter circular. The large vascular and nervous trunks lie outside of the muscular tunic; the arteries, after furnishing numerous branches for this substance, penetrate the mucous tis-

sue and end in the sub-epithelial venous capillaries of the papillæ, as single and double capillary loops. These vessels, increasing rapidly in size, and communicating with one another by numerous anastomoses, constitute a venous plexus proper for the mucous membrane, the general direction of which is parallel to the urethra. Muscular bands, derived from the muscular coat, press in between these large veins. The thickness of the network gradually increases towards the membranous portion of the urethra. The venous branches passing outward diminish in size and number, and take up the veins of the muscular tunic. We have described the urethra about the membranous and prostatic portions, as these are the parts concerned in the operation of lithotomy; and we thus see that Heule is correct in regarding this portion of the urethra as having a cavernous body (vide *Handbuch der systematischen Anatomie des Menschen*, Splanchn., p. 365), for it is evident from the explanation given that with an increased influx of blood to the arteries of the urethra, the reflux through the returning veins cannot be proportionate, and that stasis of the surplus blood in the large venous networks must result.

All this clearly demonstrates the fact, that of all canals the urethra is formed of most dilatible structure; and, if any one will take the time and pains to test this upon the cadaver, he will find that the facts will fully bear out the histological characteristics of the canal.

T. O. SUMMERS, M.D.

NASHVILLE, TENN.

### SHORTENING IN FRACTURES.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—In the report of the proceedings of the American Medical Association, held at Chicago last month, contained in THE MEDICAL RECORD for June 23, 1877, it is said that on the third day of the sessions of the Surgical Section (Thursday), and immediately after the reading of a paper by Dr. Jones, of Chicago, on Otolaryngology, Dr. Lewis A. Sayre, of New York, rose to a question of privilege, and entered his protest against the resolution adopted by the Section on Tuesday, to the effect that shortening followed fracture, in spite of any methods of treatment now in use. It was a confession that the profession couldn't properly treat a fracture, and he protested against such a declaration.

I was chairman of the Surgical Section, and was not out of my place from the opening to the close of its sessions. Dr. Sayre addressed the Section on several occasions in reference to other matters, but he never "rose to a question of privilege"—he never entered a "protest"—and never said a word upon the question of the results of treatment in fractures of the long bones.

This is a simple matter of fact, attested by the Secretary, Dr. Owens, and which I am sure Dr. Sayre, who is now in Europe, will thank me for correcting.

Very truly yours,

FRANK H. HAMILTON.

### EXTERNAL PRESSURE IN DELAYED LABORS.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—While reading the "Transactions of the Cincinnati Obstetrical Society," as published in the *Am. Jour. Obstetrics* for July, 1877, I was reminded of a case in my own practice where external pressure, after Von Ritgen's method, was favorably employed.

The case is as follows: Mrs. W., aged 35, third pregnancy, called me about 9 A.M., April 22d; complained of pains most of the night from midnight; found the os quite well dilated; membranes ruptured about 10 A.M., and at 11.15 A.M. was delivered of a small male child. A few moments' time sufficient to determine the existence of a second child to come.

All pains ceased upon the birth of the first one, nor could they be provoked by a liberal administration of fl. ext. ergota, borate soda, or exercise. After waiting till 3 P.M., I resorted to interrupted external pressure, and had the satisfaction of delivering the second child (female) at 4 P.M. Both placentas soon followed with only slight hemorrhage. The second child lived but a few minutes.

The mother made a good recovery. Query: Did ergot injure the child? I think it did.

I believe the advantages referred to by Dr. McMechan as set forth by Abegg, of Dantzic (see Transactions of Cin. Obs. Soc.), are real, not imaginary, and that many tedious labors may be materially shortened by a judicious employment of external pressure.

If you deem this note worthy of publication in THE RECORD you may use it.

Respectfully yours,

D. J. CHITTENDEN, M.D.

MCINTYRE, PA., July 18, 1877.

### THE SO-CALLED MILK FEVER AND ANTISEPTIC MIDWIFERY.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—In THE RECORD for June 2, 1877, there appears an article by Blair D. Taylor, M.D., on the above named subject, in which he gives his experience in the use of antiseptic injections after delivery as a preventive of the so-called milk fever. He claims that the fever, usually observed at or about the time the milk is secreted, is not due to that process, as was formerly taught, and is now taught, I think, by the majority of obstetricians, but that it is due to the absorption of decomposed *debris*, etc., in the uterus and vagina through the lacerations and abrasions necessarily produced by the act of delivery. This fever, then, must be a form of septic poisoning, and can be prevented by antiseptic means. Dr. Taylor states that he has never observed any fever in any case where injection of a weak solution of carbolic or salicylic acid has been used. I wish to state that my experience during the past two and one-half years in this matter fully agrees with the statements made by Dr. Taylor. A much-respected teacher, Prof. E. S. Dunster, used to teach this view, and I presume does so now. I can go a little further than Dr. Taylor, and say that when only simple tepid water was injected, within six hours after the birth of the placenta, and continued, I have never seen a temperature above 99°.

It is my rule to order tepid water to be used twice a day for a week, commencing about six hours after the placenta has been delivered. If any factor is observed in the discharges, carbolic acid, salicylic acid, or Condy's fluid is added to the water in small quantities.

Now and then I have found a patient who will object to the use of these injections, but in no case who they have been faithfully used have I heard patient express any other than much comfort from their use they will, in fact, ask to have them continued.

Respectfully yours,

URANUS O. B. WINGATE, M.D.

WELLESLEY, MASS., July 27, 1877.

A NEW BANDAGE ROLLING MACHINE.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—In a conversation with Dr. Frank H. Hamilton, the evening of June 6, 1877, in Chicago, he remarked that one of the greatest drawbacks to the use of the plaster-of-Paris bandage in the treatment of fractures was the length of time occupied in preparing them. I then described a machine I had constructed for me for that purpose by my able friend Frederick N. Elliott, D.D.S., in 1873.

The machine consists of a second-hand sewing-machine stand, with the treadle arranged so as to bring the fly-wheel and pulley to the left. Above the lower pulley is a smaller one, between a forked support that is bolted to the stand. This pulley should be five or six inches above the top of the table, with a screw on the right free end, external to the fork, to fit an ordinary gas-burner. Solder into the end of the gas-burner an hexagonal wire some six inches in length, screw this on the upper pulley and attach a band over the two pulleys, and you have an excellent foot-power bandage-roller, leaving both hands free to manipulate the bandage, which is rolled very rapidly. It is difficult to draw a bandage off a round spindle when wound tightly. To wind a plaster bandage take a small cigar-box and pass two wires parallel to each other, two inches apart, and half an inch from the bottom of the box. Now bolt this box to the table so as to have the wire opposite and parallel to the spindle, between the spindle and the operator, so that the bandage, in passing under both wires as it goes from under the wire nearest the spindle, will make an angle to the plane of the table of about forty-five degrees.

When rolling the bandage, which should be of the flimsiest flannel, let it pass under both wires and on the spindle, so that in rolling it will pass under instead of over the spindle. By keeping the box full of plaster, and not rolling the bandage too tight, the proper amount of plaster is rubbed in. The reason for having two wires for the bandage to pass under is that, as it passes over the edge of the box and under the first wire, all wrinkles are smoothed out and the meshes of the cloth held open better for the reception of the plaster.

The next day Dr. Henry O. Marey, of Massachusetts, exhibited before the Surgical Section of the American Medical Association a hand plaster-roller, when Dr. Hamilton called on me to describe my apparatus, but not being present in that Section I could not do so, but send you the description.

I only claim the invention of the plaster-rolling attachment in the above machine, as the rest of the credit belongs to Dr. Elliott, and as an ordinary bandage-roller it is superior to any hand machine I have ever seen. Mr. E. T. Dobbins, of the firm of John Wyeth & Brother, of Philadelphia, being in my office the other day, was so pleased with the machine that he said he would have one made as soon as he reached home, as with the hand machines the winding was much slower and required two boys, and this can be managed easily by one.

It is needless for me to say anything in favor of plaster dressings, since Drs. Hamilton, Sayre, Marey, and others, have written so much better than I could about them. I would especially commend Dr. Henry O. Marey's article upon Plastic Splints in Surgery, in the June 28, 1877, number of the *Boston Medical and Surgical Journal*.

By fastening a dentist's emery-wheel on a gas-bur-

ner with shellac varnish you have an excellent attachment to the machine for sharpening knives, needles, etc.

I remain, very respectfully,

WILLIAM A. BYRD.

327 JERSEY STREET, QUINCY, ILL., July 12, 1877.

ARMY NEWS.

*Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from July 29 to August 4, 1877.*

HALL, WM. R., First Lieut. and Asst. Surgeon. To accompany, until otherwise ordered, the cavalry commanded by Capt. Whipple. S. O. 20, Hdqrs. Dept. of the Columbia, in the field, June 29, 1877.

BUELL, J. W., First Lieut. and Asst. Surgeon. Granted leave of absence for one month on surgeon's certificate of disability, with permission to leave limits of the Department. S. O. 137, Dept. of Texas, July 28, 1877.

Medical Items and News.

CONTAGIOUS DISEASES.—Comparative statement of cases of Contagious Disease reported to the Sanitary Bureau, Health Department, for the two weeks ending August 4, 1877.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-Spinal Meningitis.	Measles.	Diphtheria.	Small-pox.
July 28.....	1	13	43	4	36	28	0
Aug. 4.....	1	5	36	3	31	22	0

THE LATE DR. WILLIAM E. H. POST.—At a special meeting of the Vaccinating Corps of the Health Department of the City of New York, held July 26, 1877, the following resolutions were adopted:

*Whereas*, Death has removed from us Dr. William E. H. Post, in the opening of an earnest and useful life.

*Resolved*, That in his death we have lost a valued and beloved friend, an earnest and efficient associate, and that the profession has lost an able and promising member.

*Resolved*, That we tender to his family our warmest sympathy in their great affliction.

*Resolved*, That this expression of our sorrow at his unlooked for death, and testimonial of our appreciation, be forwarded for publication to THE MEDICAL RECORD, of this city, and that a copy be sent to the family of our late fellow-member.

P. B. WYCKOFF, M.D., *Chairman*.

W. J. PURCELL, M.D., *Secretary*.

A CASE OF SPINA BIFIDA.—At the Congress of German Surgeons held in Berlin in April last, Prof. Langenbeck presented a boy, twelve years of age, who, when an infant, presented a spina bifida in the lower part of the back. The tumor, which was about as large as the fist, was treated by puncture and injection of iodine. At the present time the only mark of the affection is a small cicatricial depression; the bones have developed, and now close the spinal canal completely.

**BOYLSTON MEDICAL PRIZE QUESTIONS.**—The Boylston Medical Committee, appointed by the President and Fellows of Harvard University, consists of the following physicians: J. B. S. Jackson, M.D.; D. H. Storer, M.D.; Morrill Wyman, M.D.; Henry J. Bigelow, M.D.; Richard M. Hodges, M.D.; Calvin Ellis, M.D.; Samuel Cabot, M.D. At the annual meeting, held June 4, 1877, it was voted that no dissertation worthy of a prize had been offered on either of the subjects proposed for 1877.

The following are the questions proposed for 1878: 1. Antiseptic Treatment. What are its essential details? How are they best carried out in practical form? 2. Diphtheria. Its causes, diagnosis, and treatment. The author of a dissertation considered worthy of a prize, on either of the subjects proposed for 1878, will be entitled to a premium of seventy-five dollars.

Dissertations on the above subjects must be transmitted, post-paid, to J. B. S. Jackson, M.D., Boston, on or before the first Wednesday in April, 1878.

The following are the questions proposed for 1879: I. The relation of animal contact to the disease known as hydrophobia. II. Evidence showing that so-called "filth diseases" are not dependent upon "filth." The author of a dissertation considered worthy of a prize on either of the subjects proposed for 1879 will be entitled to a premium of two hundred dollars.

Dissertations on these subjects must be transmitted as above, on or before the first Wednesday in April, 1879.

**ST. JOHN'S GUILD.**—The floating hospital of St. John's Guild is making its usual summer excursions, and with the usual success. Although it sounds well to the public, there is something more needed than the mere crowding together a number of children for a daily excursion of a few hours.

**THE AMERICAN PUBLIC HEALTH ASSOCIATION** will hold its fifth annual meeting in the city of Chicago, Sept. 23d-25th. An unusually interesting meeting is expected.

**DR. R. L. PARSONS** has resigned his position as Medical Superintendent of the New York City Lunatic Asylum, to accept a similar position in the Kings County Lunatic Asylum, Flatbush, N. Y.

**MEDICAL DEGREES FOR WOMEN.**—The Senate of the University of London decided at its last meeting, by a majority of five, not to postpone the admission of women to medical degrees until all the other faculties are open to them.

**RHODE ISLAND MEDICAL SOCIETY.**—At the last annual meeting of this Society, the following officers were elected for the ensuing year: *President*, Dr. Charles H. Fisher, North Scituate; *Vice-President*, Drs. Edward T. Casswell and Geo. P. P. Baker, Providence; *Recording Secretary*, Dr. W. E. Anthony, Providence; and *Corresponding Secretary*, Dr. E. M. Harris.

**DEATH FROM ANESTHETICS.**—A death recently occurred at the East Suffolk Hospital (London) during the administration of bichloride of methylene and ether for the removal of diseased bone from the leg of a patient, aged fifty-six, who was suffering from syphilitic caries. Death occurred during a convulsion. For some unexplained reason, the coroner forbade a post-mortem, and consequently the immediate cause of death was not ascertained.

**WESTCHESTER CO. (N. Y.) MEDICAL SOCIETY.**—The Seventy-Ninth Annual Meeting of the Westchester Co. Medical Society was held at White Plains, N. Y., June 26th. Papers were read as follows: Lead Poisoning, by

Dr. Chapman; Life as a Source of Disease, by the retiring President, Dr. Sawyer; Fractures of Spine, by Z. Edward Lewis; Modern Facilities for Early Diagnosis of Disease, by Dr. Helm. The annual election resulted as follows: For President, Isaac T. Collins, M.D.; for Vice-President, H. Ernest Schmid, M.D.; for Secretary, J. F. Chapman, M.D.; for Treasurer, J. T. Wood, M.D.; Censors, Drs. Helm, Linson, and Pelton. Essayists, Drs. Schmid, Coutant, and Horton; Delegates to Amer. Med. Association, Buffalo, 1878, Drs. Sawyer, Wood, Parsons, Schmid, and Coutant. The Society adjourned at 4 o'clock to meet at Rye Beach, Tuesday, Oct. 16, 1877.

**THE RUSSIAN ARMY.**—The medico sanitary arrangements of the Russian army are said to be very complete.

**CAPSICUM IN ALCOHOLISM.**—Dr. C. A. Owens (*Lancet*) finds capsicum very useful in alcoholism. He uses it in combination with nux vomica and dilute nitrohydrochloric acid, in an infusion of gentian. The tincture is a good form to give the remedy. The prescription is particularly valuable in the treatment of drunkard's dyspepsia, morning sickness, faintness, etc.

**CARELESS OVARIOTOMY.**—A case of rather peculiar nature which occurred at the Alfred Hospital, Melbourne, has given rise to considerable discussion among the profession at the antipodes. It was that of a woman operated on in the hospital for ovarian tumor, and in whose abdomen after death a *sponge* and a pair of small *bull-dog forceps* were found. The *Australian Medical Journal*, No. 187, reproduces the report of the hospital committee, and gives a long account of the inquest held on the exhumed body of the patient.

**FEMALE CLINICAL INSTRUCTION.**—The Royal Free Hospital is to administer to the clinical wants of the Women's Medical School of London.

**TRICHINOSIS.**—One hundred and seventy-one soldiers have been suffering from trichinosis at Dudenhofen, Germany.

**HOME HOSPITALS.**—The British medical press is agitating the feasibility of establishing hospitals exclusively for pay patients.

**SMALL-POX IN LONDON.**—At last accounts the weekly mortality from small-pox in London was 55.

**THE HOSPITAL SUNDAY FUND.**—The Hospital Sunday Fund in London lately reached £20,000, and much exceeds the amount received within the same time in a previous year.

**CALCIFICATION OF TUBERCULOSIS OF LUNG, AND THE RISKS OF THE MUTUAL LIFE INSURANCE COMPANY OF NEW YORK.**—Dr. G. S. Winston, Medical Superintendent of the Mutual Life Ins. Co., in regard to Dr. Both's article (July 21), writes: "So far as he supports his statements by references to the 'New York Mutual' as having insured, subsequent to his treatment, Messrs. B. I. Baker and W. G. Craibe, he is laboring under a misapprehension. No such parties were ever insured in this company. Please make this public, as the Mutual Life Insurance Co. of New York, popularly called the 'New York Mutual,' never under any circumstances insures such risks."

**OVARIOTOMY DURING PREGNANCY.**—Mr. Spence Wells, of London, has performed ovariectomy nine times during pregnancy, and with but one fatal result.

**DR. EDWARD WARREN (Bey)**, a prominent American physician of Paris, has just been created a Knight of the Order of Isabel the Catholic, as a recognition of the professional skill displayed by him in the successful treatment of some Spanish personages of high position.

## Original Lectures.

### GENERAL BRONCHITIS — BRONCHIAL HEMORRHAGE — GENERAL CARDIAC HYPERTROPHY AND DILATATION — PNEUMONIA AT THE APEX.

A CLINICAL LECTURE DELIVERED AT BELLEVUE HOSPITAL,

By ALFRED L. LOOMIS, M.D.,

PROFESSOR OF PATHOLOGY AND PRACTICE OF MEDICINE IN THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF THE CITY OF NEW YORK.

(Reported for THE MEDICAL RECORD.)

**GENTLEMEN:**—This man, *æt.* 35 years, a marble-cutter by trade, was admitted to the hospital to-day. On account of the stupidity present, apparently in consequence of the disease, only an imperfect history of his case can be obtained. The most that can be learned is that about ten days ago he was taken with spitting or vomiting of blood, not certain which, and the hemorrhage has continued up to the present date. He has been in the habit of drinking lager-beer freely. He is not emaciated, his face is somewhat puffy, and his feet and legs are moderately œdematous. His abdomen presents about the normal appearance, and the superficial veins are not enlarged. The apex beat of the heart is so diffused and indistinct that it cannot be located by palpation. The area of cardiac dullness is normal. There is tenderness in the epigastrium. The spleen is of normal size. The area of hepatic dullness is normal. There is some dullness upon percussion over the right lung, but it is not sufficiently marked to be regarded as abnormal. On auscultation sibilant and sonorous râles are heard over the anterior portion of the chest, with prolonged expiration.

Respiratory murmur is heard over the entire chest posteriorly, although from the spine of the scapula downwards there is increasing dullness upon percussion, and at the bottom of the pleural cavity on both sides there is flatness.

Sonorous and the finer sibilant râles are also heard over the upper portion of the chest.

Mucous râles are heard over the entire chest, both anteriorly and posteriorly. There is no cardiac murmur. Nowhere over the chest is the percussion sound emphysematous. The pulse is 72, and the temperature normal.

The urine is light colored, and contains albumen in considerable quantity. It has not been examined for casts. He has not had a chill so far as can be ascertained. There is a marked tendency to stupor.

There are three important points which have been obtained from the history and our examination:

1. From the history we learn that there has been hemorrhage, and probably it was hæmoptysis.
2. From the examination we learn that there is œdema of the feet, legs, and face.
3. There is a feeble heart-sound, and the contractions are so weak that the apex beat cannot be located by palpation. There is no evidence of enlargement of the heart.

From the evidence obtained by physical examination there can be no question but that this man has general bronchitis.

There is probably but little doubt that he is also suffering from Bright's disease, although examination in that direction must be continued. Granting that these two diseases are present, do they explain all the symptoms, and constitute a complete diagnosis?

There is probably some pulmonary œdema at the lower portion of the lungs posteriorly, although there are no crackling sounds to be heard.

I think it is quite possible to have pulmonary œdema affecting the intervesicular tissue without giving rise to râles, but simply to dullness upon percussion. Probably such is not infrequently the case in connection with Bright's disease, for any disease in which there is an enfeebled capillary circulation.

But how is it possible to have bronchial hemorrhage with Bright's disease, or without the physical signs of pulmonary consolidation, or valvular disease of the heart? In this case, I think, the bronchial hemorrhage can be accounted for by reference to one point in the history, namely, he is a marble-cutter, and has followed that occupation during the last twelve or fourteen years. In that class of persons bronchial hemorrhage is quite apt to occur when some disturbance of the circulation ensues, such as arises from slight attacks of bronchitis. The occurrence of such hemorrhage does not indicate the necessary development of phthisis, but such persons are very likely to develop phthisis of the fibroid variety, because when the bronchitis is once established in those engaged in this and kindred occupations it is persistent: they do not usually recover from it.

The prognosis in this case is rendered more unfavorable than it would otherwise be by the kidney complication. The fact, however, that there is general bronchitis, accompanied with hemorrhage, leads almost certainly to the conclusion that the bronchitis will be a permanent one if he continues at the same kind of work. He has doubtless had more or less cough with expectoration for some time, and that will continue. After a while he will have another attack of bronchitis, and farther changes of a fibrous character will take place in the bronchial tubes, ultimately will extend into the lung substance, and after years of such persistent bronchitis, with repeated attacks of a more acute character, fibrous induration of the lungs becomes marked, and he has that form of phthisis known as fibrous phthisis. In all probability this man will not live until such extensive changes have taken place in the lungs, for the condition of his kidney is probably such as will soon bring about a fatal termination. It seems probable that it is a case in which the kidney disease had had considerable duration.

The treatment should be first directed to the relief of the symptoms depending upon the Bright's disease. In addition, it is well to apply dry cups over the chest. If he dies within a week or ten days he will probably die with œdema of the lungs and brain. He would be more likely to have pulmonary œdema did he not have the bronchitis. I do not think that the bronchitis in this case is secondary to the Bright's disease. Bronchitis secondary to Bright's disease is not an infrequent occurrence, but occurring under those circumstances it has a character differing from that which is present in this case; there are more moist sounds than we have here. In this case the physical signs indicate that we have to deal with a condition in which there is marked congestion of the bronchial tubes, without that abundance of secretion which so often occurs in connection with the bronchitis accompanying Bright's disease. In the bronchitis secondary to Bright's disease, there is usually a profuse liquid secretion. In this case we have, for the most part, the dry râles indicating tumefaction of the mucous membrane of the bronchial tubes as the result of congestion. The attending hemorrhage shows that this congestion has been considerable, therefore has a local cause, and is not due to Bright's disease.

GENERAL CARDIAC HYPERTROPHY AND DILATATION—  
PLEURISY WITH EFFUSION—PHYSICAL SIGNS OF  
PNEUMONIA WITHOUT THE DISEASE.

This patient, gentlemen, gives us the following history: Previous to twelve months ago she supposed herself to be in perfect health, but at that date she began to suffer particularly from palpitation of the heart, and soon afterwards her feet began to swell. She did not suffer from pain in the back at that time, nor did she have headache or nausea. Her urine was passed in diminished quantity, and, as she says, was "heavy looking." She has always been temperate, and has never had rheumatism. She has had cough during the last two weeks, and has suffered somewhat from pain in the precordium; she has never spit blood. She has suffered from palpitation more or less for a number of years, but it became a distressing symptom twelve months ago, and she was obliged to leave her work because of it and shortness of breath. She is not able to tell us whether there was any swelling of the face at the time the œdema of the feet first appeared. There is no œdema of the feet at the present time. The urine contains a small quantity of albumen.

On *inspection*, it will be noticed that there is a certain amount of blueness of the lips, and the capillary circulation in the skin is somewhat interfered with. Respiration is rather hurried. There is a heaving motion over the entire anterior portion of the chest, and the apex-beat is visibly diffused over a great area. There is a distinct epigastric pulsation.

On *percussion*, it is found that the area of dulness in the precordial region is very much increased; extending from an inch to the right of the right border of the sternum over to two and a half or three inches to the left of the left nipple.

On *auscultation*, it is to be noticed that there is loss of rhythm in the cardiac pulsations; one in about every four or five beats is lost, and there is also great irregularity of the heart's action. The sound which is heard over the precordium is rather continuous; it is not difficult to distinguish the first from the second sounds, but it is difficult to separate the one from the other. There is a murmur present, but you will not be able to place it with either sound of the heart. At times the murmur is lost entirely in the confusion of the heart's action. When present, it is difficult to say that it is connected with the first or the sound of the heart, but it has a blowing character, which suggests that it comes with regurgitation. Another thing to be noticed in auscultating the precordial spaces is the entire absence of the respiratory murmur.

From these physical signs the question seems to be settled that there is hypertrophy of the right and left side of the heart, with dilatation of the ventricles and the aorta. But why do we not hear the murmur of them in either regurgitation or obstruction? I feel almost positive that there is regurgitation at the aortic and also at the mitral orifice, for there are times when I am confident that both an aortic and mitral murmur can be heard. When the patient gets excited the murmur is temporarily lost, and that is not an uncommon occurrence in connection with heart disease, when the disease is as extensive as it is here. If for any reason the action of the heart becomes a little irregular, the distinctness of the murmur is lost to such an extent as to make diagnosis difficult, if not impossible. In such a case, however, you may take it almost for granted that there is regurgitation at the aortic, and also at the mitral orifice. As a general statement it may be said that the more extensive the disease, the less distinct

are the signs of valvular lesions of the heart. When the heart is extensively diseased in the way of dilatation and hypertrophy, and becomes excited, for instance by the presence of a pneumonia, while the pneumonia continues the signs of valvular lesions will be absent, simply because the heart is beating more rapidly than usual. So it is when the heart's action becomes accelerated from any cause, there may be temporary absence of the valvular murmur. It has been maintained by some observers that simple disturbance of the pulmonary circulation is sufficient to cause loss of murmurs; but it seems to me, and I think the majority of observers entertain the same opinion, that the loss of murmur under these circumstances is due to increased rapidity of the heart's action, and not to pulmonary obstruction.

We may reasonably expect in this case to find some evidences of pulmonary œdema. On examining the lungs posteriorly, however, we find no special evidence of such trouble, but there is found a peculiar condition which perhaps is worthy of special notice.

As may be noticed, there is flatness upon percussion in the infra-scapular space on the left side. It is a noteworthy fact that, when pericarditis occurs with such an amount of effusion as to fully distend the pericardium, the physical signs of pneumonia in the second stage, dulness on percussion and bronchial breathing, will be present on the left side posteriorly in a great many instances in which there is evidently no pneumonia whatever.

The idea which Dr. Scott (student) has advanced with reference to explaining these physical signs by pressure of the heart upon the lung, thus giving rise to pulmonary changes, is one which has been entertained by others, but pressure will give rise to evidence of pneumonia as shown by bronchial breathing only; the dulness upon percussion does not appear to bear out the diagnosis. In this case, however, percussion gives evidence of something which encroaches upon the pleural cavity in such a manner as to produce flatness, and as we auscultate it is found that all respiratory murmur and voice sounds below the lower border of the scapula are abolished. Formerly I regarded the bronchial breathing and dulness upon percussion which were developed upon the left side posteriorly during the progress of a case of pericarditis, with a large quantity of serous effusion, as evidence of pneumonia in the second stage; but I have come to believe that these physical signs may be present under those circumstances, and in that situation, without the presence of pneumonia. I believe so for the reason that, as the effusion accompanying the pericarditis disappears, the bronchial breathing and dulness upon percussion disappears, and without any râles being present at any time during the progress of the case.

It is well for you to make a note of this fact, as it may save you from a good deal of perplexity at some future date.

In the case before us, we obtain the normal respiratory murmur down to a point corresponding to the lower border of the scapula, but below that point there is flatness upon percussion, absence of respiratory murmur, and the presence of other physical signs, indicating fluid in the pleural cavity. The question can be settled positively by the introduction of an exploring needle.

[The house physician, Dr. Morris, stated that the chest had been aspirated, and bloody serum obtained.]

But you may ask the question, why should this woman have heart disease, inasmuch as she gives no history of having had rheumatism? Endocarditis

may occur independent of rheumatism; it may occur in connection with Bright's disease or the infectious fevers. It does not occur often, independent of rheumatism, but such an occurrence is not an impossibility.

In this case, the kidney disease, if present, is probably due to chronic congestion.

This is a heart which, probably, will fail to respond to digitalis, for the reason that the dilatation is secondary to the hypertrophy.

The insufficiency upon the right side of the heart is that which gives rise to the greatest danger in this case.

PNEUMONIA AT THE APEX ASSOCIATED WITH ALCOHOLISMUS—QUESTION WITH REFERENCE TO PROGNOSIS.

The patient before us gives us the following history, which has one or two points of interest:

Female, *at.* 30 years; intemperate. Three weeks ago, when considerably under the influence of liquor, she got her feet wet. The next day she had "a kind of chill," but suffered from pain nowhere, except under the sternum. She took to her bed, and was kept there, because of the headache, nausea, pain in the chest, and general feeling of discomfort. About two weeks subsequently she had a chill, followed by fever, and soon after began to cough and expectorate. During the past four or five days she has been expectorating a sticky, semi-opaque material, having a creamy-yellow color, characteristic of pneumonia in many cases. It has not the ordinary brick-dust color. Her countenance, as you see, is flushed; her tongue is flabby, red at the edge, coated in the centre, and brown and dry, and there are sordes on the lips and teeth. Her pulse is regular, full, easily compressed, and numbers 105. The temperature has ranged between  $101\frac{1}{2}^{\circ}$  F. and  $103^{\circ}$  F., and the respirations are 40. There is no delirium.

From the cough, the character of the expectoration, and the rapidity of the respiration, we turn our attention to the lungs, with the expectation of finding evidence of pneumonia.

On *pulpatio*n it is found that vocal fremitus is absent upon both sides of the chest at the lower and posterior portion, the voice not being sufficiently strong to develop it.

On *percussio*n there is slight dullness over the lower portion of the right lung, but more marked over the scapula.

On *auscultatio*n vesicular respiration is heard all over the lower posterior portion of both lungs, and there are no râles. When the apex of the lung is reached, over the region where the dullness upon percussion is most marked, bronchial breathing is distinct.

Over the anterior portion of the chest marked dullness upon percussion is found in the infra-clavicular region upon the right side, and bronchial breathing is distinct down to the nipple. As we listen close under the breast, some crackling sounds, short and sharp, are heard at the end of inspiration and commencement of expiration.

They are probably subcrepitant râles and pleuritic friction-sounds.

From the history of this case and the physical examination, we reach the conclusion that this patient is suffering from pneumonia affecting the apex of the right lung. It is not a case of pleuro-pneumonia, because pleurisy has not preceded the pneumonia. The ordinary history of pleurisy is absent, while the ordinary history of pneumonia is present. Again, she has not sufficient pleurisy to give the disease the name

pleuro-pneumonia. In a case of pleuro-pneumonia, the pleurisy is a prominent element and precedes the development of the pneumonia. We will, therefore, call this a case of pneumonia.

Within the last twelve hours the temperature has fallen to  $101^{\circ}$  F., which indicates that the disease is progressing favorably. The pneumonia is in the third stage, has had sufficient duration to be on the way towards recovery, and the general appearance of the patient is such as indicates approaching convalescence.

Let us suppose, however, that at the end of the tenth, or twelfth, or fourteenth day of the disease some remedy is administered for the purpose of controlling the temperature, does the fact that the temperature declines a few hours after the administration of the remedy prove that it has done so because of the influence of the agent employed? It does not. In this case, for example, the temperature has fallen within the past twenty-four hours, and although quinine was given for the purpose of lowering it, we must also take into consideration the fact that the disease had reached a point where we might reasonably expect a decline in temperature *without* treatment.

Fifteen grains of quinine were administered last evening, and this morning the temperature was found to be  $101^{\circ}$  F. instead of  $103\frac{1}{2}^{\circ}$  F., the height before the exhibition of the remedy; but it is altogether probable that the quinine merely assisted the decline. Again, the dose administered was not of sufficient size to produce a fall in temperature.

We have here a woman with intemperate habits, a pneumonia at the apex of the lung and in the third stage, and what is the prognosis? Is there any more danger on account of the pneumonia being at the apex instead of at the base of the lung?

In a very large proportion of cases the pneumonia of drunkards will be found at the apex, and if they recover at all, they recover about as rapidly as those cases in which the disease is found at the base. It is not so much the situation of the pneumonia in this class of cases as it is the amount of pleurisy that affects the prognosis. In proportion to the amount of pleurisy present, I expect the resolution to be rapid or slow. If a large amount of pleurisy accompanies the pneumonia, complete resolution is a very fortunate occurrence, and, perhaps, in the great majority of cases, does not occur.

On the other hand, where pneumonia occurs at the apex in persons whose habits of life have been correct, there is always a suspicion that there is some condition behind the pneumonia which will favor phthisical development.

[At the clinic the following week, it was reported that resolution of the pneumonia was nearly complete and the general condition of the patient rapidly improving.]

GROWTH OF THE HUMAN HAIR AFTER DEATH.—Dr. Caldwell, of Iowa, states that in 1862 he was present at the exhumation of a body which had been buried two years before. The coffin had sprung open at the joints, and the hair protruded through the openings. On opening the coffin, the hair of the head was found to measure eighteen inches, the whiskers eight inches, and the hair on the breast five to six inches. The man had been shaved before being buried. In 1847, a similar circumstance occurred in Mercer County, Pa. In digging a grave, the workmen came upon the skeleton of a man that had been buried ten years. The hair was as firm as during life, and had grown to a length of eleven or twelve inches.

## Original Communications.

### CASE OF FISTULA VESICO-UMBILICALIS CONGENITA—PATENT URACHUS.

By A. ROSE, M.D.,

NEW YORK.

THE urachus is a plainly visible stem which connects the sac formed by the allantois with the anterior wall of the rectum. About the second month of the fetal life its posterior portion is enlarged and becomes the bladder, the upper part of which is continued into the umbilical cord by means of a tubular canal, which is still called the urachus, remaining for some time pervious, and then becoming obliterated. This tubular canal tapers off, while the bladder is enlarged into a receptacle, although it retains its spindle-shaped form and passes into the urachus without any particular definition. The anterior portion of the urachus is that part which forms the above-mentioned canal; it is obliterated in the adult when it becomes a fibromuscular cord, and forms the so-called ligamentum suspensorium—seu medium—vesicæ.

Already at the end of the 17th century Peyer maintained, in opposition to Caspar Baubin and Regner de Graaf, that the urachus was pervious during the fetal period. J. G. Walter (*Annot. acad. Berol.*, 1775) tried to prove that the urachus was formed by a continuation of the inner membrane of the bladder, being in the healthy and natural state a pervious canal at every period of life and in both sexes, which admits of the passage of a small probe or mercury. Ruysch and Hildebrandt also agree as to its being a hollow canal, while Meckel and Arnold claim that it is impervious and only occasionally found hollow. According to other investigators it is obliterated either towards the end of gestation or soon after birth. E. H. Weber believes it to be a continuation of the vesicular mucous membrane. Husehke, however, thinks the urachus is connected with the bladder only by the muscular layer of the latter.

Luschka's recent anatomical and microscopical investigations of the urachus on male adult bodies demonstrate that, at least in a majority of individuals, it is at least partially hollow, being lined, as claimed by Walter, by mucous membrane, although it does not always communicate with the bladder. In many cases he found the mucous membrane of the bladder to continue into a tubular prolongation of the base of the bladder, about 2 mm. thick. A small opening, as if produced by the insertion of a needle, can be perceived within the bladder; usually, however, there is only a small indentation or no trace whatsoever visible. He also observed that, wherever a cavity existed, its calibre was not of equal size, but crinkled and modulated, resembling acinous glands. Some of these nodules are tubular, while others are pediculated, thus forming small cysts. A partial constriction of the canal itself causes the formation of cysts, reducing the rest of the canal to a threadlike size. These cysts are usually very small, but sometimes they attain the size of a millet or pea. The abnormal permeability of the urachus is mentioned in several works of pathological anatomy (Foerster, Rokitsansky, Voigtel, Klebs, and others). In many cases reported it was only proved by the escape of urine through the umbilicus without making any further investigation about the condition of the

urachus. In other cases a considerable widening of the urachus has been ascertained. Mention is also made of the existence of urinary calculi in the urachus, and cases are also reported of acquired permeability of the urachus. Such a case is described only recently by M. Jacoby, of Bromberg (*Berlin. klin. Wochenschrift*, 1877, No. 15). In this case retention of urine, brought about by a stricture of the urethra, caused the formation of a vesico-umbilical fistule.

The most remarkable and instructive cases are, in my opinion, those communicated by Dr. C. E. E. Hoffmann, of Basel. Believing that his valuable essay (Carl Ernst Emil Hoffmann, "Zur pathologisch anatomischen Veränderung des Harnstranges," *Archiv der Heilkunde*, Leipzig, 1870, pp. 373-390) is not yet known in the current English literature, I shall here give a short synopsis for the purpose of directing attention to the exceedingly valuable original:

The first case of Hoffmann is reported in connection with one observed by Meckel, who found in a ripe embryo of a sow a sac-like enlargement of the urachus one inch in breadth and width, distant about four inches from the umbilicus. Hoffmann's specimen comes from a grown hog, appears like a sac constricted in the middle, thus dividing into two equal portions. On being inflated, both halves appear to be of an elliptical shape. The lower portion measures, while inflated, 31 centimetres in length, and 22 centimetres in diameter; the upper portion is 25 centimetres long and 24 centimetres broad. Both portions communicate with each other through an opening 9 centimetres in width. The upper portion was closed towards the umbilicus; the entire sac was situated between urethra and umbilicus.

The following is the second case: Herman R., a student of divinity, born 1842, had from his youth a large abdomen, creating a good deal of laughter among his schoolmates on this account. Thinking adiposity to be the cause of it, he tried to reduce it by fasting, but without avail. Since May, 1866 (in his 24th year), his abdomen increased considerably in size, followed by shortness of breathing, which latter circumstance caused his father and brother (both being physicians) to examine him thoroughly, when fluctuation was plainly revealed in and around the umbilical region. As the dyspnoea had in the meantime increased, a puncture was made in August, 1866. Fever, vomiting, and abdominal pains ensued. A thin, reddish-yellow liquid was emptied. No account was kept of the quantity.

Afterwards the patient was subject, from time to time, to attacks of fainting, but enjoyed otherwise good health until 1868, when the abdomen again increased in size. He entered the hospital on June 30, 1868.

His general appearance is cachectic; suffers greatly from dyspnoea. On August 25th a puncture was made, and about 6 litres of a bloody liquid emptied, which contained a good deal of cholesterine, red globules, and detritus. A third puncture was made on September 12th, when 18½ litres of liquid came away. 17 litres escaped at the fourth puncture, November 4th. The last puncture was made May 12, 1869, when 6 litres of liquid were obtained. The post-mortem examination was made on the 18th of May, 1869. Fifty litres of liquid were found within the sac, which filled the larger portion of the peritoneal cavity.

The contents of this sac weighed about 100 pounds, while the body itself weighed, previous to the section, only 192 pounds. Its external side is lined by a serous membrane of the peritoneum. This is connected

internally with a firm layer of fibro-cellular tissue, abounding in elastic fibres, which is lined by several layers of well-developed pavement epithelium. The bladder is contracted, and contains but a small quantity of yellowish urine. The mucous membrane presents a pale appearance. The urachus is completely closed at its vesicular termination; along its course towards the umbilicus an exceedingly small sized cavity was found. Near the umbilicus the fibrous tissue of the urachus passed into the subperitoneal layer of the anterior abdominal wall.

The third case was that of a post-office employé, who died of acute peritonitis, May, 1869, at the age of 28 years. At birth the umbilicus was still open; its closure was effected in the third year by the application of caustics. In 1868 an induration of the size of a goose's egg was observed about midway between umbilicus and symphysis pubis. This gradually increased and was punctured several times, followed by the escape of urine and a purulent bloody liquid. The patient grew rapidly thin, losing 25 pounds in 4 months. On January 31, 1869, he weighed only 88 pounds. On account of objections raised by the family of deceased, only an incomplete post-mortem examination could be obtained. The attending physician removed the entire tumor, with the bladder, and sent it to Dr. Hoffmann for further examination. A very small opening was found in the centre of the navel communication, with a sac which extended to the base of the bladder, measuring 18 centimetres in length, and, at its middle portion, 2.5 centimetres in width. The cavity opens into the bladder through an opening 3.5 centimetres wide, which is found to have undergone carcinomatous degeneration.

The following cases occurred in my own practice:

Charles King, 11 years of age, was brought to my office in May, 1876, by his grandmother. She informed me that she was present at the birth of the child, and observed in the region of the umbilicus a roundish, whitish swelling, of the size and shape of a duck's egg, which was easily reduced and kept so by means of a proper bandage by the attending physician. An opening had, however, remained, through which nearly constantly urine escaped. From his first to his seventh year the child was taken to an orthopaedic institution of this city, where compresses were applied by means of adhesive strips, without obtaining any result. Considerable urine escaped through the navel, wetting the clothes and causing a terrible smell.

The boy presented a strong and healthy appearance. In the centre of the umbilicus an opening existed large enough to admit the passage of a uterine sound. The urine passed both through the urethra and the fistule. Dr. A. Jacobi, to whom I showed the child, introduced a catheter through the umbilical fistule into the bladder, through which he injected water into the bladder and again emptied it.

On June 3, 1876, I performed the operation, kindly assisted by Drs. F. H. Hamilton, A. Jacobi, and others, by making a raw surface above the fistule, detaching from below the fistule a flap corresponding in size to the freshened surface, and drawing it over the fistule and sewing it to the wound, which was then covered by compress of cotton wadding. But little suppuration occurred, which I controlled by the application of a solution of acetate of alum. At the end of the first week a very small quantity of urine escaped through a small opening, which, however, soon closed upon the application of nitrate of silver.

I saw the patient again several months after the operation, when I convinced myself that the fistule

was entirely closed, and that the urine passed through the natural channel only.

On June 22, 1877, I showed the patient to Dr. Jacobi, who filled the bladder with water through an elastic catheter. He succeeded in injecting 12-13 ounces; the organ expanded evenly and in a normal pear-shaped manner.

Very complete and valuable reference to the literature of our subject is found in the above-quoted essay of Hoffmann, also in a thesis of Dr. Ernst Veiel, "Die Metamorphose des Urachus," Tübingen, 1862. H. Luschka has reported the results of his researches about the construction of the human urachus in the 23d volume of *Virchow's Archiv*. A drawing of vesico-umbilical fistule by Froriep is contained in W. Roser's *Handbuch der anatomischen Chirurgie*.

Since the publication of Hoffmann's paper, I. I. Charles has published an essay on the treatment of patent urachus (*British Medical Journal*, Oct. 16, 1875. Meeting of the British Medical Association). This case is of great practical importance; it concerned a boy, one year old, in whom the urachus had remained patent; nearly all the urine escaped through it, and but a few drops passed through the urethra.

Charles found the cause to be congenital phimosis. After performing circumcision the urachus closed spontaneously, and the urine passed through its normal outlet. He therefore recommends thorough examination of the urethra and penis before deciding upon a plastic operation for closing the patent urachus, since the removal of any existing anomaly of the former may be followed by the closing of the latter.

M. Jacoby has also reported a case of congenital vesico-umbilical fistule (*Berlin, klin. Wochenschrift*, 1877, No. 15, "Zur Casuistik der Nabelfisteln"), in addition to the case of acquired fistule mentioned above. In this case of congenital fistule at first compression was tried, but as this did not succeed, the red-hot iron was twice applied, and the fistule closed.

## DISLOCATION OF THE STERNAL END OF THE CLAVICLE UPWARDS.

By W. C. SHAW, A.M., M.D.,

PHYSICIAN TO MERCER HOSPITAL, PITTSBURGH, PA.

This form of dislocation is very rare. Malgaigne has recorded four such cases, and Dr. Frank H. Hamilton two, in his fourth edition of his excellent work on Fractures and Dislocations. Mr. Bryant has seen a double dislocation of this variety in a sewing-girl at 20 years, produced by being violently crushed while in a crowd.

His second case was caused by a fall on the shoulder. The first case which Dr. Hamilton met, a patient of Dr. Rochester's, was caused by being caught under the bar of a gateway, while riding on a load of wood; the second by a fall upon the shoulder; in one of my own cases, by a drunken man falling down a flight of stairs, striking upon his shoulder; in the second, most likely, occasioned by a difficult labor, lasting the greater part of two days, according to the mother's story. This dislocation seems to have been produced in all the reported cases by a force exerted upon the end and top of the shoulder, in consequence of which the clavicle at the sternal end is lifted or pushed upwards from its bed, freeing it from its numerous ligamentous attachments to the sternum, and in some cases rupturing the costo-clavicular ligament. The symptoms are depression of the shoulder of corresponding side, and elevation of the sternal end of the clavicle.

There is increase of space, consequently, between the clavicle and the first rib.

There is shortening of the space between the acromion process of affected side and centre of sternum. There is an apparent tumor above the sterno-clavicular articulation.

The sterno cleido-mastoid muscle is relaxed on affected side; but this depends upon the position assumed by the patient, being more tense in upright position, especially the sternal fibres of the muscle. There is considerable pain at seat of injury, on motion of the arm. Reduction has been found easy; but retention has not been accomplished perfectly in any case reported, or under my observation. The dislocation has in no case seriously impaired the functions of the arm.

**CASE I.**—Michael Mulay, 25; male; Ireland; laborer. Admitted to Bellevue Hospital April 24, 1874. Family and personal history good. Is an occasional drinker. Denies venereal. On week previous to admission, after taking a drop too much, he fell down a flight of stairs, striking upon the top of his shoulder and the side of his head.

Next morning, after recovering his senses, he felt the bone out of place on his chest, and found that it hurt him to move his arm.

On admission, was found to have a dislocation of the clavicle upwards, and slightly forwards.

*Oct. 27th.*—To-day his arm was put up in Dr. Sayre's apparatus for fractured clavicle, and, in addition, a strap of adhesive plaster was first fixed to his back, or, rather, to the band passing around the body, and then brought forwards across the clavicle. At the point of articulation of clavicle with the sternum, a tightly rolled bandage was placed over the free extremity of the clavicle, and the strap of plaster drawn tightly across this, and then carried downwards, and fixed to the chest in front. This addition to the apparatus brought the bone into position, and held it there.

*May 1st.*—Patient has been kept in bed upon his back. Deformity is scarcely perceptible.

The strap across the clavicle gets loosened frequently, and is adjusted by the orderly, and tightly pinned to the waist-strap below.

*May 6th.*—Since last note patient has remained constantly in bed, lying upon his back.

To-day the straps were removed, and it was found that the deformity had been removed to a great extent, there being merely a slight prominence over the upper margin of sternum, perceptible to the touch. Would not be noticed by the eye, except by careful inspection. His arm was carried across the chest, and confined by a roller of bandage, and patient was allowed to sit up.

*May 7th.*—Patient wishes very much to go home, and, as it is not deemed advisable to keep him constantly on his back in bed, a bandage was applied so as to confine his arm to his chest; and he is this day discharged.

Deformity has been to a considerable extent removed. Patient has free use of arm of that side.

**CASE II.**—Charles L., 2½ months. The mother has always been healthy. Denies venereal. Her husband is a brakeman, and, although I have repeatedly left invitations for him to call at my office, have been unable to learn his history personally. His wife says that he is very delicate, is 28 years old, and partially paralyzed.

Fell on the street, with hemiplegia of left side, about one year ago. Is troubled with headache. This is their first child.

The mother says that she had a very difficult labor, and desired the application of the forceps; but the attending physician did not think it best to use them. The child was fine and large, having apparent health till it was about two months old, when it began to lose flesh, and seemed to suffer pain, especially on washing. A friend suggested that there must be something wrong with the child, and, after diligent search, noticed a "lump on its neck." Owing to sore breast on right side, this breast dried up, and, not having enough milk, she gave it cow's milk, with crackers broken into it. Baby not thriving well for two weeks, she sent for me, April 11, 1877.

Found it emaciated, of a peculiar hue of skin, uttering a moaning, husky cry, snuffling through the nose. Temperature normal; pulse 160. Abdomen was tense and tympanitic.

Presented a copper or light reddish, dusky eruption on all the extremities, neck, and back of head, and on the face, averaging in size that of a coffee grain. Some were larger, and others were smaller. It seemed to me a clear case of inherited syphilis, though the mother gave no such history. I prescribed a colic remedy at the time and a change of diet.

The mother then directed my attention to the "lump in its neck," which I recognized as a dislocation of the clavicle upwards, at the sternal end. It seemed to project forward some little as the child sat upon its mother's knee. As it would lie back, with its head extended over the mother's arm, the deformity would almost become reduced; but the end of the clavicle would project backwards somewhat while in this position.

The patient always rested better in this position, and the indication for successful treatment would seem to be to keep the patient as much in this position as possible, or, when up, to have such an apparatus applied which would as nearly answer the indications as possible. The child was too weak, and the skin too tender, to make use of any regular dressing.

*April 13th.*—Child is not suffering much pain when kept upon its back, with head extended over pillow; but the eruption was more marked. This does not appear in the least itchy. Seems to take its nourishment better.

*April 16th.*—Child breathes freer, but will not recover.

I placed a band of adhesive plaster obliquely across the chest, over scapula of affected side, and over point of injury, placing a pad of lint over the sternal end of the bone, beneath the plaster. Ordered anti-syphilitic treatment, but with little hope of recovery.

*April 17th.*—Patient was evidently dying when I saw it this morning. Died soon afterward.

From the history of the delayed and difficult labor, and the positive assurance given that the child has met with no accident since birth, I am inclined to think that the dislocation took place at birth. The violent contraction of the uterus, forcing the shoulder upon the floor of the pelvis, would fulfil the conditions as cause of such an accident.

The syphilitic taint may have formed an element as to causation.

However, I will leave this for my professional brethren to solve.

The plumpness and apparent good health of the child prevented the discovery of the accident until it became emaciated from the fatal malady, which also was congenital.

I present, therefore, this case as the second disloca-

tion of clavicle at birth. The first case was that of Mr. Fergusson.\*

This is the only one of this variety, the rarest of the three forms of dislocation, which has yet been reported, to my knowledge, as occurring at birth.

As to treatment in dislocations of the clavicle, referring only to those at the sternal end as being dislocations of this bone, there is not very much encouragement to be hoped for in the treatment, at least as derived from those on record.

In order to reduce any of the three dislocations, the shoulder must be carried upwards, outwards, and backwards, precisely as we would reduce a fracture of the bone. There are innumerable modes of applying as many kinds of apparatus. Should I meet another case, I would use the same dressing as employed in Case I, or try that employed by Tyrrell in his case of dislocation backwards of the clavicle, as related by South in his note to *Chillus's Surgery*.

He placed a splint across the shoulders, with a pad between it and the spine, and bandaged the shoulder back to this.

The splint was kept on a fortnight, and the bone being then quite steady in its place, she was then allowed to remain in bed without a bandage.

The articulation became in four weeks quite as firm as that of the other side.

I should feel disposed to use some such mode in all the varieties, with oblique strap and pad in addition in cases of dislocation upwards or forwards.

Very fortunately, the usefulness of the arm in all cases is very little diminished, except to raise weights above the head, and there is comparatively little pain or disturbance to the person afflicted, except in some cases of dislocation backwards.

In the December number, 1875, of the *Monthly Abstract of the Medical Sciences*, is a note of a case taken from the *Archiv der Heilkunde*, vol. xvi., where a girl, *æt.* 16, had on one side only a rudiment of a clavicle, an inch and a half long, loosely connected with the sternum, and on the other side, where also the sterno-cléido-mastoid was also absent, one clavicle only  $\frac{3}{4}$  inch in length. Both humeri could be easily brought in front of the chest until they touched; yet there was no functional disturbance, the absence of the clavicles being compensated by muscular action, especially in regard to fixations of the scapulae.

## Progress of Medical Science.

A CASE OF PERNICIOUS ANÆMIA TERMINATING IN MEDULLARY LEUKÆMIA.—The history of this case was given in a paper recently read before the *Gesellschaft der Charité Aerzte*, in Berlin, by Dr. Litten. The patient, a previously healthy young woman, was confined in November, 1875. She nursed her own child for five months, and then another child for nine months, her milk being always abundant, although her food was poor and insufficient. In the latter part of January, 1877, she began to feel badly, and became weak and pale. Vomiting soon set in, and was repeated several times daily. On February 11th, when she was admitted into the Charité, she presented the signs of the most extreme anæmia; the skin and membranes were of a waxy paleness, but at the same time she was quite corpulent. She had no appetite, and vomited what she did eat. The pulse was 112, and moderately full;

a loud and sharp systolic murmur was heard all over the precordial region; there were numerous small retinal hemorrhages, some with whitish centres; the retinal arteries had a strikingly pale-red color, and the optic nerves were exceedingly pale. Microscopical examination of the blood showed the red corpuscles to be greatly diminished in number, but unchanged in form. Microcytes were almost absolutely wanting; the white corpuscles were slightly increased in number, most of them belonging to the larger variety. There was no enlargement of the spleen or liver. For three days the condition of the patient remained unchanged, but on the fourth day a marked increase in the white blood-corpuscles was discovered: on that day the proportion was fifteen red corpuscles to one white; on the next day it was nine to one; on the third day four to one, and on the fourth day, on which death took place, the ratio was still smaller. About half of the white corpuscles were of the large variety, with distinct, vesicular nuclei, and sometimes nucleoli. The nucleoli were generally large, and in many took up most of the cell. Some cells had two nuclei. Meanwhile no enlargement of the spleen or glands, and no tenderness over the bones could be discovered. During these four days the patient suffered from frequent, severe attacks of dyspnoea. During the entire course of the disease fever, œdema, and albuminuria were entirely absent.

*Autopsy*.—Heart, marked fatty degeneration; valves normal; cavities slightly dilated. General muscular system of body, in contrast to the heart, exceedingly dark-red in color. All the internal organs excessively anæmic. Spleen, Malpighian follicles slightly enlarged. Kidneys presented a number of whitish-gray, miliary nodules, which projected slightly above the surface. The medulla of the long bones was of a dirty gray color, and contained circumscribed spots, which were greenish-yellow in color, and almost fluid in consistence, and also smaller spots which were more gelatinous, and were surrounded by red zones. Microscopical examination showed the puriform and gelatinous masses to consist principally of the same large, round, granular cells, with distinct vesicular nuclei (medullary cells), which were found in the blood, along with a few lymph-corpuscles of ordinary size, some red blood-corpuscles and cells containing blood-corpuscles. Fat-cells were almost entirely wanting, as were also nucleated red blood-corpuscles. In the Malpighian corpuscles of the spleen the lymph-corpuscles were more closely packed than normally; the nodules in the kidneys consisted of masses of lymph-cells, which extended a short distance into the cortex. The muscular fibres of the heart were fatty.

In his remarks on this case, Dr. Litten asserted that from the history it was evident that it was, in the beginning, one of simple pernicious anæmia. The leukæmia set in only four or five days before death, although it was not impossible that a disease of the medulla of the bones existed before the blood gave evidence of its existence. He ascribed the fatty degeneration of the heart to the pernicious anæmia, and stated that leukæmia never gave rise to such general and intense fatty degeneration of that organ. In four fatal cases of pernicious anæmia that had come under his observation, the fatty degeneration of the heart was very marked, while, in sharp contrast to it, the general muscular system was well developed, and of a deep-red color. The adipose tissue in these cases was well developed, and in some of them abundant. The abdominal organs were exceedingly anæmic; in two of the cases the spleen was slightly enlarged and hard, and contained large numbers of cells that enclosed blood-

\* Fergusson, *System of Practical Surgery*, Amer. Ed., 1853, p. 202.

corpuseles. Fatty degeneration of the liver, kidneys, and pancreas was present in some, but not in all of the cases. The medulla of the bones was examined in only two of them. In one it was macroscopically unchanged; when examined with the microscope it was found to contain nucleated red blood-corpuseles and large numbers of microcytes, but very little fat. In the second case it looked like raspberry jelly, was very poor in fat, and contained a few microcytes and a considerable number of nucleated red blood-corpuseles. The latter were rather large and round, and contained a vesicular, usually eccentrically located nucleus, which was generally colorless, but sometimes colored. Some cells had two or three nuclei. The medulla cells were increased both in number and size. During life microcytes had not been constantly found in the blood in these four cases. The white corpuseles seemed sometimes slightly increased in proportion to the red, but the increase never reached such a degree as to raise the suspicion of a leukemic disease of the blood.—*Berliner klinische Wochenschrift*, November 19 and 26, 1877.

**RESECTION OF THE INFRA-ORBITAL NERVE.**—At the meeting of the *Société de Chirurgie* in Paris, on June 13th, M. Tillaux reported a case of resection of the infra-orbital nerve in the canal of the same name. The patient, a servant, thirty-one years of age, had suffered for eleven years from facial neuralgia, and from purulent discharge from the antrum. A free opening had been made into the antrum and drainage secured; injections of iodine, and cauterization of the interior of the antrum with nitrate of silver, chromic acid, and the hot iron, had been tried in turn, but these and all other methods of treatment had secured only temporary improvement. The pains were exceedingly severe, and started from the infra-orbital foramen, extending into the globe of the eye. The side of the face was excessively tender. Resection of the nerve having been decided on as a last resort, M. Tillaux made a horizontal incision analogous to that recommended by Nélaton for disarticulation of the upper jaw, and then a vertical incision terminating at the ala of the nose. The nerve was exposed at its exit from the canal, and was surrounded by a ligature, and the branches given off from it were dissected out for some distance. The periosteum of the floor of the orbit was then stripped from the bone and the globe of the eye raised up in a coffee-spoon. The nerve could now be seen in its canal through the transparent bone; it was laid bare by the aid of a chisel, and was divided deep in the orbit by a pair of curved scissors. By drawing on the thread previously applied, the entire nerve was removed. It appeared a little large, but microscopical examination showed it to be normal in structure. After removing the nerve, an opening was made into the anterior wall of the antrum Highmore, and on introducing his finger M. Tillaux found osteophytes on the superior wall. The floor of the orbit presented no lesion. The operation was performed on May 1st, and eleven days later the patient was able to return to her home completely cured. Since then she had not complained of any pain at all.—*La France Médicale*, June 16th.

**ARSENIC IN ALBUMINURIA.**—Dr. T. Lauder Brunton reports the case of a man, who for nine years suffered from intermittent albuminuria, with debility, and at times loss of flesh. The albuminuria was worse in summer, was brought on by exertion in the morning and by the use of meats and fats, and completely disappeared when a farinaceous diet was rigidly adhered to. The patient suffered much from acidity, especially

in the morning. There was no œdema. The heart and lungs were healthy. No casts were found in the urine, but it was not very frequently examined for them. Quinine increased the albuminuria, and so did phosphorus. Digitalis caused it to diminish slightly, but the drug disagreed with the stomach, and had to be stopped. On account of its supposed action on the secreting structures of the kidney, Fowler's solution was finally ordered at meal times in three-minim doses. The albumen disappeared from the urine almost at once, and the patient was able to do much more work than before, without bringing it back. Dr. Brunton thinks that the albumen in this case was derived in great measure from the intestinal canal—that, in consequence of the imperfect digestion of albuminous substances, albumen was absorbed from the intestines, and excreted by the kidneys, much in the same way that white of egg would have been, if the patient had swallowed several raw eggs at once. As the pancreatic juice first converts coagulated albumen into a soluble form, before finally digesting it, it seemed probable that imperfect pancreatic digestion was the cause of the albuminuria. Pancreatic emulsion was administered on two occasions, but it did harm rather than good. This was probably because the fat caused acidity of stomach, for, when pancreatine alone was given, without the fat, the albuminuria disappeared.—*The Practitioner*, June, 1877.

**DRAINAGE OF THE EYE BY CATGUT.**—M. de Wecker, who introduced the use of drainage in ocular therapeutics, has of late successfully employed catgut for this purpose. He has used it in cases of glaucoma, detachment of the retina, and corneal and sclerotic staphylomas. The catgut he uses is preserved in carbollated oil, and after the fat has been dissolved out with ether, it is carefully dried. A single or double thread of it is then passed through the eye, and lightly knotted in front. It falls off, in children at the end of three or four days, and in adults after six or seven days. An active filtration without symptoms of irritation takes place at the points of entry and exit of the thread. M. de Wecker claims that by this treatment the intra-ocular tension can be reduced much more efficaciously than by iridectomy.

Dr. Nicati has studied experimentally the influence of drainage by catgut on the eyes of animals, and draws the following conclusions from his observations:

1. Drainage by catgut introduced across the equatorial region of a healthy eye, diminishes its tension to a considerable extent, and for a period as yet undetermined. Drainage of the anterior chamber has a much less pronounced durable influence on the intra-ocular tension.

2. The catgut is dissolved in a few days in the fluid of the conjunctival sac, but in the vitreous humor, the aqueous humor, and the cornea, it takes a long time to disappear.

3. The absorption of the catgut is preceded by a vascular new formation in the vitreous humor and the cornea.

Dr. Nicati believes that the happy results obtained by M. de Wecker in the treatment of anterior staphyloma by drainage are due to the development of a sclerosis consecutive to the marked vascularization of the cornea, the sclerosis being developed while the tension of the eye was diminished.—*Gazette des Hôpitaux*, June 28th.

**PRESCRIBING DRUGGISTS.**—The *Med. Press and Cir.* quotes the portion of our report of the Connecticut State Medical Society bearing upon the above subject.

# THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, August 18, 1877.

## MEDICAL CLIQUISM.

THE filling of several hospital vacancies during the past few months calls to mind the means which are usually adopted to secure the end. The desirability of these appointments always fills the lists with eager applicants, and compels a competition of interests which is widespread and various. In fact, no professional man knows how strong or how weak he is until he becomes a candidate for a hospital position. Every part of his character is thoroughly canvassed before the board of managers, and if they do not know everything concerning his social antecedents, his professional standing, individual merit, and all other details concerning him, it is no fault of his friends or of his enemies. So evenly matched are the two parties that when one blows hot the other blows cold, so that by the time the managers get ready to vote they always have a very exalted opinion of physicians in general and the candidates in particular, and yet we are invariably told that the contests are always honorable, and the parties behind the curtain smile accordingly.

It is always interesting, on all such occasions, to note the particular influences which are generally at work. But above all, those of the different cliques are brought out perhaps with a distinctness which, if not glaring, is at least sufficiently defined to be unmistakable to the initiated. We make these remarks in no disparagement of the candidates who have been successful, but merely for the purpose of illustrating some general facts connected with professional cliquism as it exists in this and other large cities.

We are often informed, with the seeming positiveness of authority, that there is no such influence in existence; that true merit is always the recognized basis of preferment, and that he who works will surely win. Contrary to our wish, we are beginning to think that this is oftener the exception than the rule.

There are always several so called professional rings which exist in large towns and cities. The principal ones are those which revolve around a particular college, and are almost absolute in their exclusiveness. The members of the faculties and the lesser lights are bound by an honorable understanding to look after each other on any and every occasion.

And no one can conscientiously say that they do not do so. In fact, such action to each other shows cliquism to perfection.

It would be amusing, if it were not somewhat serious, to witness the anxiety of the college men concerning the proper filling of these places, for there has never been a vacancy in any of these institutions in which the colleges have not in some way meddled. These schools seem to own the majority of the hospital appointments. The faculties vote themselves in as teachers, and then claim, on that account, the usual facilities for clinical instruction. Of course every reasonable person acknowledges the force of this argument, and it is only occasionally that any one dare to defy those who claim the right to farm out clinical material. They often come to grief, as in one of the later struggles; but the principle upon which the fight is fought is always good, and never can lose in strength by defeat. On the contrary, we think that there is a growing disposition on the part of competent men—if the existence of such can be allowed outside of a faculty—to ignore college influences, and boldly assert their rights.

The college ring is usually a perfect one, and contains all those elements of self-interest which give it its greatest strength. It is well understood that no case for consultation goes begging outside the circle. The professor of medicine always sends his surgical cases for opinion to the professor of surgery, and so on to the end of the chapter. Unless we can conclude that a given college contains all the talent, we may sometimes doubt if the dealing with the patient is just. But this is an affair of conscience, upon which we do not care to dwell. What is true of colleges is also true of smaller associations, and even of individuals. It is hardly possible to estimate the number of smaller influences and interests which make up the complete history of medical cliquism.

No one would object to the extent of the latter if it were governed by those principles which stimulate honorable motives and sanctify ordinary friendship.

Generally speaking, the moving power rests in a few individuals who have merit and management combined. They are kings for themselves and Warwicks for others. Naturally they gather around them numerous hangers-on, who rejoice in the privilege of doing the bidding of their chief. To be outside of such influences is to have few, if any, chances of success; to be in the ring is often the making of professional fortune. The youngster who strikes the fancy of a great man has the world, in a professional sense,

at his feet. As assistant, partner, or special consultant, patients are crowded upon him, and he becomes a success from the start. Hospital positions are found him; college lectureships and the like come from the mere asking. He is not allowed to fail if he would. Such men are always formidable antagonists in the college or hospital lists; in fact, we have known of some timid aspirants who have given up against such odds from the very start. But it is necessary that these things should be, that each little circle should take care of itself, and feudalize its interests so that the great political machinery of medicine should harmonize with what may be called honorable struggles for preferment and place.

## Reviews and Notices of Books.

**BOOK OF MEDICAL INFORMATION AND ADVICE.** By J. WARBURTON BEGGIE, M.D., F.R.S.E., etc. London: T. Nelson & Sons, Paternoster Row. Edinburgh and New York, 12mo, 259.

This is a very useful manual, prepared by the late Dr. Warburton Begbie, of Edinburgh, and now for the first time, after having passed through several editions anonymously, appears with his name upon the title-page. Although the work is of small size, it contains an immense amount of valuable information for laymen who by necessity or other circumstances are placed beyond the reach of physician or surgeon. It is thoroughly practical, and deserves the endorsement of the profession.

### KINGS COUNTY MEDICAL SOCIETY.

THE proceedings of the Kings County Medical Society contain many papers of general interest.

Dr. Mattison gives an exhaustive review of the subject of opium inebriety; the chief points being that the habit is a disease which claims two classes for its victims: first, those who employ the drug, per physicians' prescriptions, without a thought of the danger supervening; and second, those who, with an inordinate desire for stimulants, have recourse to it as one demand or another for its use may be uppermost.

The treatment advocated is principally tonic. The value of alcoholic stimulants is doubtful: by some it is esteemed, by others condemned as worse than useless. Physical restraint is counselled, in so far as to place the patient in an asylum, where he can be controlled, and the drug administered only as necessity requires.

Another paper by Dr. Alexander Hutelings, on the Nitrite of Amyl, is full of practical suggestions. The *modus operandi* appears to be by arresting the process of oxidation in the tissues.

Dr. Geo. M. Beard contributes a practical essay on the electrolytic treatment of *naevi*, which are divided into three classes: first, those which are beneath the skin and do not affect the surface, except through pressure; second, those which are in the skin—the so-called port-wine stains; third, those which are raised more or less above the surface of the skin. Subcutaneous *naevi* are to be treated like aneurisms. Insulated needles are inserted, and one pole—by preference the positive—may be used, the other being applied on some indifferent point. There is danger in case a too strong current is used, or continued for too

long a time. *Naevi* situated above the surface of the skin may be treated by insulated needles and strong or mild currents, according to size. The most difficult forms of *naevi* to treat are the so-called port wine stains. Both mild and strong currents are used, with varying success, the difficulty in these cases being to know just when to leave off.

Dr. C. H. Giberson gives a description of a new urethrotome designed especially for the treatment of strictures of large calibre. Several cases are cited, and, judging from the success following their treatment, the new instrument will doubtless prove a valuable adjunct to the armamentarium of the urologist.

We have not the space to notice the other papers, but we hope that the Kings County Society will continue to publish their transactions yearly, as we have seldom met with more interesting records of medical and surgical practice.

**HOW TO USE THE OPHTHALMOSCOPE:** Being Elementary Instructions in Ophthalmoscopy, Arranged for the Use of Students, with thirty-five illustrations. By EDGAR A. BROWNE, Surgeon to the Liverpool Eye and Ear Infirmary, and to the Dispensary for Skin Diseases. Formerly Demonstrator of Anatomy in the Liverpool Royal Infirmary School of Medicine. Philadelphia: Henry C. Lea. 1877.

THE method of using the ophthalmoscope is clearly depicted in this little volume; not only for the advanced student, but for the beginner, who is so often discouraged by lengthy descriptions, and almost incomprehensible technicalities. Indeed, the plan of the book is so simple that any student, with the slightest imaginable amount of ophthalmological knowledge, may follow its pages intelligently and with profit.

As the author says: "The arrangement has been dictated by what appear from personal experience to be the wants of the average student who is anxious to learn, but distracted by a multitude of facts and theories, for the most part dimly and phantasmagorically seen, cannot acquire the full complement of practical knowledge in the brief periods between the dreaded crisis of his examinations." The writer also says that he may appear to have treated the subject in too elementary a manner, and that the illustrations may be too rough. As to the first: the book is intended for beginners, but will convey much valuable information, in a concise form, to the more experienced. The illustrations, thirty-five in number, are all that could be desired, their very simplicity emphasizing the one dominant fact and suppressing the less material. The work is divided into four sections, of which the first treats of optical principles—light, reflection, refraction, focus; the second, of the ophthalmoscope, the mode of using it, and oblique illumination; the third, of appearances of healthy structures; the fourth, of appearances of disease, opacities in cornea and lens, to ascertain the refraction of the eye, conical cornea, astigmatism, changes in the optic disc, retina, choroid, etc.

THE Report of the Resident Physician of Bingham Hall for 1876 chronicles the death of the late resident physician, Dr. George Cook, who conceived the project of establishing this institution in 1855. Dr. D. R. Burrell, the present superintendent, has endeavored to follow Dr. Cook's plan of having no fixed rules for the guidance or movements of patients, individualizing each case, and dispensing, as far as possible, with hospital routine or system. One hundred and twenty-two persons were treated during 1876, seven of whom died.

GENERAL INDEX OF N. Y. MEDICAL JOURNAL. By JAS. B. HUNTER, M.D., Editor. D. Appleton & Co. 1877.

The General Index to the New York Medical Journal, from April, 1865, to June, 1876 (twenty-three volumes), by James B. Hunter, M.D.; New York: D. Appleton & Company, 549 and 551 Broadway, is very thorough and complete in many respects. It is a neat volume of 144 pages, and shows considerable care and labor on the part of its author.

REPORT OF THE UNITED STATES MARINE HOSPITAL SERVICE. 1875.

We learn that with the 30th of June, 1875, the seventy-seventh year of the operations of the Marine Hospital Service was closed, and the fourth year of its organization on the present basis. To estimate the amount of work done in this department, it is stated that relief extended to ninety-four sea and inland ports of the United States, and 12,509 seamen were treated in hospital, while 2,070 others were relieved at the offices of the surgeons. The number that have thus been cared for was larger than ever before. We are surprised to see that previous to 1873, medical officers were appointed without any preliminary examination, though since that time the requisite qualifications have been tested by a suitable examination, and yet as the new order of things depends upon a *regulation*, and not upon a *statutory provision*, "there are not wanting those who persistently endeavor to break down this barrier against mediocrity and ignorance." It seems to be with the Marine Hospital Service as with the other departments of government: political influence is constantly being brought to bear to secure appointments, while special fitness for the place is thought of minor consequence. The Supervising Surgeon-General very properly urges that some legislative provision be made for the preliminary examinations of surgeons, since the government holds the hospital fund in trust for the seamen, and the sacred duty of trusteeship implies that it should exercise as much care in determining the qualifications of its officers as in selecting officers for the army and medical corps.

Some papers of interest on special diseases, such as yellow fever at the ports, are valuable and interesting. We should be pleased to see more of them, as the officers of the government often have unusually favorable opportunities for studying certain classes of disease, of which our practitioners can know little, because they see them so seldom. This is true *par excellence* of yellow fever and cholera.

PRIZE ESSAY—AMERICAN MEDICAL ASSOCIATION. Excision of Larger Joints of the Extremities. By H. CULBERTSON, M.D., Professor of Ophthalmology in Columbus Medical College, Assistant Surgeon U. S. A., retired, etc. Philadelphia, 1876.

The work before us, as its title indicates, received the prize at the American Medical Association, and was published by that body. It now equals in size the volume of the Transactions, and altogether has been rather an expensive venture for the Association. Although the work as it stands is one of the most valuable contributions to surgery which has been read in many years—in fact, in the special branch of which it treats, is exhaustive—why it should have received the prize in question does not appear. But the mistake on the part of the Prize Committee will not detract from the work as a standard one for reference for any year to come. To give some idea of its scope, we may mention that nearly four thousand cases of excision of the different joints have been collected,

tabulated, analyzed, and made the basis of practical deduction of the greatest value regarding the different methods of operation, after-treatment, etc. The great care and exhaustive labor which the author has expended upon the work makes it an indispensable addition to the surgeon's library; in fact, the volume contains everything necessary to be known in connection with the history and treatment of the affections of all the larger joints requiring excision. It is suitably illustrated with woodcuts showing the surgical anatomy of the joints in different aspects, and altogether is a complete guide for every species of operative procedure upon these parts. We are glad to see that work published, and believe it to be an invaluable contribution to the subject, but nevertheless, in our opinion, it does not represent that character of work which entitles it to the special distinction of an Association prize.

AN ELEMENTARY TREATISE ON PRACTICAL CHEMISTRY AND QUALITATIVE INORGANIC ANALYSIS. Specially Adapted for the Use of Laboratories, etc. By FRANK CLOWES, D.Sc., London. From 2d London edition. Philadelphia: H. C. Lea, 1877. 12mo, pp. 372.

This little treatise is intended to supply the student in the chemical laboratory with all the practical directions which are necessary for the prosecution of his work. The arrangement of the subjects in the volume is a natural one, and is calculated to lead the learner step by step to the intelligent appreciation of the more difficult problems. We have no doubt that the work will meet with favor in this country, and, as in England, become one of the standard authorities of its class.

TRANSACTIONS OF THE PATHOLOGICAL SOCIETY OF PHILADELPHIA, VOL. VI. Edited by JAMES TYSON, M.D., Prof. Gen. Pathology and Morbid Anatomy, Univ. Penn. Philadelphia: J. B. Lippincott & Co., 1877. 8vo, pp. 153.

VOLUME SIX of this series contains the report of the proceedings for the sessions of the Society from September, 1875, to July, 1876. The subjects are arranged as usual under the anatomical division which is at once the most simple as well as natural. They comprise specimens illustrating diseases of the osseous, digestive, circulatory, respiratory, and nervous apparatus, besides numerous miscellaneous specimens, some of which are from the lower animals. The material is well worked up, and causes the present volume to rank in value and interest with any of its predecessors.

FRUIT AND BREAD, A SCIENTIFIC DIET. By GUSTAV SCHELKEYSEN. Translated from the German by M. L. HOLBROOK, M.D., etc. New York: M. L. Holbrook & Co.

This is a labored attempt to prove the utility of fruit and bread as an exclusive article of diet. It is filled with extravagant statements, absurd propositions, and ludicrous deductions. With a certain class we have no doubt it will be enthusiastically received.

DIABETES MELLITUS.—Dr. D. Ray, of Pottersville, Cal., writes: "For more than ten years I have been treating diabetes with perfect success with the fluid extract of bugleweed (*sycopus virginicus*), simply observing the lessons taught by chemistry in regard to diet. The dose is a teaspoonful five times a day."

THE NEW DISCOVERER OF ANÆSTHESIA does not seem to be very well received by the medical press in spite of his distinguished advocate. No journal as yet has given an unqualified opinion in favor of the new candidate for fame.

## Reports of Societies.

### NEW YORK PATHOLOGICAL SOCIETY.

*Stated Meeting, June 13, 1877.*

DR. E. G. JANEWAY, PRESIDENT, IN THE CHAIR.

OSTEO-SARCOMA OF FEMUR, SKULL, LUNG, ETC.

DR. L. A. STIMSON presented portions of the lungs, skull, dura mater, and femur of a patient from whom he had removed a central osteo-sarcoma of the lower end of the femur by amputation November 21, 1876. The history of the case and description of the tumor appear in the Transactions of the Society for the meeting of November 2, 1876 (MEDICAL RECORD, January 6, 1877).

The patient recovered speedily from the operation, and the wound healed entirely within the first fortnight. Two months later, after having been at work some time at his trade of carpentry, the patient began to cough and had a slight hemorrhage from the lungs. The cough continued with occasional hæmoptysis until the 7th of April, when he was admitted to the Presbyterian Hospital. In the meantime a hard, flat, circular tumor, half an inch in diameter, had appeared on the left frontal bone near the bregma.

On examination slight dulness was found over the upper portion of the right lung, with increased vocal resonance, sibilant and sonorous râles. The dulness increased for a week and then grew less, but the signs of bronchitis grew more marked on the right side, and toward the end of April the paroxysms of cough became very frequent and prolonged. The cough was harsh, the expectoration scanty. The dyspnea following any exertion was very distressing. The paroxysms were asthmatic in form, and were not accompanied by any cyanosis until two days before his death, which took place May 4th. The patient rose in bed, drank a glass of milk, and fell back dead.

At the autopsy the lungs were found to weigh seven pounds one ounce, and to be filled with nodules varying in size from a cherry to a child's fist. The largest of these nodules occupied the left side of the pericardium, and extended into the left lung. Some of the nodules were entirely within the lung; others projected upon its surface, and were covered only by the visceral pleura. On section all present the same appearance, with slight modifications due apparently to their relative age. A peripheral zone, equal in width to one-third or one half of the radius of the nodule, pinkish-gray in color, and of tolerably firm consistency, enclosing a soft, friable, yellow centre. In almost every nodule is found a highly vascular or hemorrhagic segment; in a few are gritty, calcareous points, the scrapings from which present under the microscope the appearances of commencing ossification; but well-defined osteoplasts, concerning the nature of which there could be no doubt, were not found, although there was no lack of elements resembling them more or less closely. In the large nodule, however, bordering on the pericardium, there is a piece of fully formed bone an inch in diameter and one-third of an inch thick, in which osteoplasts, normal in size, shape, and appearance, abound.

On microscopical examination, the nodules are found to be composed of crowded masses of round and fusiform elements containing oval nuclei, some of which are multiplying by scission. No alveolar structure.

Two of the bronchial glands had undergone entire

cheesy transformation; the others were slightly enlarged, especially a bunch lying against the posterior wall of the trachea and primary bronchi at the bifurcation, but showed no signs of sarcomatous change. Some of the smaller bronchi were filled with dark-colored, juicy clots; in all the usual signs of bronchitis, injection of the mucosa, frothy serum, were present. There was no enlargement of the femoral, inguinal, or retroperitoneal glands; no deposits in any of the abdominal viscera, all of which were apparently healthy.

The tumor of the frontal bone was an osteo-sarcoma, occupying the entire thickness of the bone, which was firmly adherent to the dura mater over a space one and a half inches in diameter. That portion of the tumor which rose above the level of the outer surface of the skull was separated from the rest by a diaphragm of dense bone, which was complete except over a small space in the centre, and was formed by the outer table of the skull, thinned by erosion on its under surface. This part of the tumor, therefore, bore a certain resemblance to an exostosis following periostitis, although composed of sarcomatous elements. It contained numerous spicule of bone, which were, of course, of new formation, and not due to rarefaction and expansion of the outer table. The inner table, as such, was entirely destroyed, and replaced by an irregular porous shell with a thickened rim, firmly adherent to the dura mater, and continuous with the central spiculæ of the tumor.

Layers of osteoblasts, with occasional individuals undergoing transformation into osteoplasts, were demonstrated several times in preparations made from different parts of the tumor, and the process thus shown to resemble that form of embryonal ossification in which the bone is not preceded by a cartilage of the same form and size.

On the under surface of the dura mater, at points within the area of adhesion, were three small red growths, the largest only the size of a large pea, projecting so far beyond the surface as to be almost pedunculated, and also composed of round and fusiform elements, with one or two points of commencing ossification (well-defined osteoplasts not found), not continuous, however, with the bone of the skull.

There is no sign of local return of the disease in the femur. The muscular and fascial attachments, especially on the inner side, have ossified, so that when examined before death the bone appeared to be enlarged. The wall of the bone has thickened for about half an inch, reducing the calibre of the medullary canal somewhat, and the latter is occupied for the same distance by spiculæ of bone adherent to the wall and to a thick fibrous diaphragm, continuous with the periosteum, which closes its cut end entirely. The canaliculi of this portion are enlarged. The interesting point is, that the medullary canal is not yet entirely obliterated, although nearly six months have elapsed since the amputation.

#### BADLY UNITED FRACTURE OF LEG.

DR. SANDS exhibited the skeleton of an amputated foot and leg, which he had removed from a lad aged twelve years, in consequence of a fracture which was badly united and which had occurred ten years ago. The fracture was occasioned by a fall, and involved both bones of the left leg a short distance above the ankle. The treatment was by paste-board splints, and great deformity ensued, there being a sharp angula projection forwards at the point of fracture. The patient was then placed under the care of a natural bone-setter, who follows the usual practice of that clas

men, by steaming, rubbing, etc. Then he was taken by his parents to an orthopaedic dispensary in Philadelphia, where the ends of the bones were filled and where he was so much benefited by treatment as to be discharged cured. Subsequently, however, the deformity returned and he was obliged to wear an apparatus to compensate for the shortening of the limb. The only remedy appeared to be amputation, which was accordingly performed with a good result. Dr. Abbe made an excellent preparation of the specimen, which showed that the union was ligamentous in character, and that the hard and soft tissues involved in the lesion were more or less contracted and atrophied.

#### EXTENSIVE CRANIAL SARCOMA.

DR. SANDS presented a specimen of intracranial sarcoma which illustrated the sequel of a case presented to the Society five years ago. In November, 1872, with the assistance of Dr. Knapp, at the Ophthalmic and Auricular Institute, Dr. S. operated upon a German, aged twenty-six years, for the removal of a soft sarcomatous tumor, which proved to be a chondrosarcoma, which originated in the left antrum. The operation consisted in throwing up a flap of the cheek, perforating the antrum, and spooning out the growth. The latter could not be removed entirely, inasmuch as it was found to extend into the bones of the face, and to an considerable distance into the frontal sinus. The operation, however, relieved the patient for a considerable length of time, and he was able to work at his occupation, that of a driver of an ice-cart, for two years.

In June of 1874 he presented himself, complaining of headache. Shortly after this he had an epileptic convulsion and entered Roosevelt Hospital, where he remained for some months. He suffered from time to time with epileptic seizures, and it was supposed that the growth of the tumor was extending into the brain. Recovering somewhat from these nervous symptoms and receiving no encouragement from his physicians, he resolved to return home and die among his friends. At the fall of 1874 he accordingly went to Europe and remained there until the close of 1875, when he visited Dr. Sands and reported himself cured. In 1876, however, his old symptoms returned. Protrusion of the left eye then showed itself, and was accompanied with complete atrophy of the left optic nerve. A second operation was performed in June, 1876, at the same institution and with the assistance of Dr. Knapp. This time the operation was conducted in a quite different way. The tumor showed itself at the inner angle of the left eye and occupied the orbit as far as the finger could reach. The periosteum was exposed by making a flap of the eyelid and a portion of the integument of the forehead. On cutting through the periosteum the bony tissue was absorbed, and its place was found occupied by the tumor, which penetrated the bony cavities of the face, absorbing the cribriform plate of the ethmoid bone and the roof of the orbit. The scoop could be passed to the right of the median line. A sufficient quantity of the tumor was removed to permit the eye to resume its proper position. The relief was, however, only temporary. Soon head symptoms developed, and he was readmitted to Roosevelt. He then suffered from paroxysmal headaches, became blind, deaf, and lost his smell, and during the latter part of his life in a sort of stupor. The tumor grew externally so as to produce a keloid deformity. The face was frightfully swollen and a sanious discharge exuded from the nostrils.

Dr. Delafield and Abbe made a preparation of

the skull. The specimen showed a very extensive invasion of the cranial cavity, the mass being the size of a large orange. It involved in absorption a portion of the bones at the base of the skull and the roof of the mouth, and in a vertical direction extended from that point to the top of the cranium. In quite a number of vertical planes there was no bony tissue whatsoever. A very thin layer of brain tissue was found covering the summit of the tumor. In some places this layer was not more than a quarter of an inch in thickness. In an antero-posterior direction the tumor extends from the front of the cranial cavity, a distance of four inches. In conclusion, Dr. Sands expressed his surprise that a patient with such an amount of disease, in such a locality, could have lived so long.

DR. DELAFIELD stated that the tumor was composed of cartilage and mucous tissue, and at the time of the removal of the specimen was almost in a diffuent condition.

DR. HEITZMANN exhibited a specimen of cystic carcinoma of the liver.

DR. BEVERLEY ROBINSON exhibited some phosphatic urinary concretions that had been voided in the urine of a man suffering from catarrhal phthisis and chronic nephritis. He believed that the coincidence of these two conditions was very rare. In support of this, he mentioned that Professor Flint found only eleven cases of this sort in six hundred cases of phthisis, and of the latter number but three or four had albumen in the urine.

DR. JANEWAY had met with phosphatic calculi associated with tuberculous nephritis, but he did not recall such a condition accompanying phthisis.

DR. DELAFIELD said that chronic Bright's disease was associated quite frequently with phthisis, but the occurrence of calculi was more commonly noticed as a clinical fact than as an autopsical revelation.

DR. HEITZMANN stated that he had examined three hundred persons who had died of tuberculosis of different organs, and in not one did he find a healthy kidney. Interstitial nephritis was a very common, almost normal occurrence in such cases, and was entirely independent of tuberculosis of the kidney.

DR. JANEWAY suggested that the reason why clinical cases showed such a remarkable absence of renal complications was due perhaps to the fact that such complications did not show themselves until the latter part of the lives of the patients.

#### EPITHELIOMA OF LEG—AMPUTATION BY GRITTI'S METHOD.

DR. WEIR exhibited the right leg, removed by amputation from a male patient of the Roosevelt Hospital, aged thirty-two years, who had suffered from an ulceration of that extremity for a number of years, gradually involving the bone, and eventually terminating in epitheliomatous degeneration. The operation, which was performed under the antiseptic spray, was by Gritti's method, through the condyloid expansion of the femur applying against the section the under surface of the patella, previously deprived of its cartilage. The patient had done astonishingly well, and presented to the members a firm and shapely stump.

#### VESICO-RECTAL FISTULA.

DR. WEIR exhibited specimens of the genito-urinary apparatus, showing a communication between the rectum and bladder, in the region of the prostate. The patient was a Frenchman, aged forty-three years, who first experienced difficulty in micturition ten months ago. There did not appear, from his history,

that there was any special cause for this. However, from that time he commenced to suffer from frequent and painful micturition, and occasionally his urine would be tinged with blood. He entered Roosevelt Hospital some three months ago with symptoms of stone, but none were found on exploration, although considerable cystitis existed. On examination per rectum a dimpling was noticed in the region of the prostate, and the cause of a diarrhoea which existed was found to be the escape of urine through an opening into the bladder at this point. Milk injected into the bladder flowed into the rectum, and a bent probe was eventually passed so as to touch a sound in the bladder. The fistula was cauterized by the galvano-caustic, and the sphincter ani stretched, to prevent escape of flatus into bladder. The effect of the heated wire was, at first, to enlarge the opening, which, however, acted beneficially on the bladder by putting at complete rest, and allayed thus the severe pain that was complained of. The patient, a few weeks after this application, became listless, apathetic, and finally comatose, with the appearance of a tumor in right hypochondrium, but without any elevation of temperature, which was remarkable in view of the condition presented by the kidneys. On post-mortem examination, the right one enlarged, forming the tumor alluded to, and both studded with numerous and large chronic abscesses.

#### PERITYPHLITIS—SPONTANEOUS CURE.

DR. POST presented a small fecal concretion which had formed itself in the vermiform appendix, and which was discharged through an incision made in an abscess in the right iliac region. Dr. Post did not see the patient until the seventeenth day after the symptoms commenced, when the incision referred to was made. The concretion was found in the pus evacuated. The child was twelve and one-half years of age. Recovery was complete and rapid.

#### SACCULATED ANEURISM OF CEREBRAL ARTERY.

DR. JANEWAY exhibited a small sacculated aneurism of the branch of the middle cerebral artery, but not the one which gave way and caused the death of the patient. It was removed from a man who was found dead. The autopsy showed hypertrophy of left heart and chronic nephritis. There was a large effusion of blood at the base of the brain, caused by a rupture of the left vertebral artery.

The Society then went into executive session.

## Correspondence.

### LAST DAYS OF THE HÔTEL DIEU, PARIS.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—The journals of the city announce the destruction of this ancient hospital as an event of the next week, and the transferring of patients to the new Hôtel Dieu directly opposite on the same square. A tour through the buildings this week with reference to its description prompts this letter. A venerable landmark in the hospital service of Paris and of Europe is to be torn down—a landmark which seems to have withstood French revolutions and Communes, and yields at last to that most natural of deaths—senility.

The Hôtel Dieu, with its garden, occupies one face of the Place du Parvis de Notre Dame. The opposite face is devoted to the new and simple hospital of the

same name, a third to the venerable church of Notre Dame, and the fourth side of the Place to a new garrison of the *Garde Républicaine*. This Place is on the Island de la Cité, which is but little larger than its fellow, St. Louis, lying just above it; the two are connected together by an iron bridge of one span, and each is also joined to the right and left banks of the Seine by very short, beautiful spans. Behind Notre Dame, at the extreme point of l'Isle de la Cité, is the city morgue. In point of history no part of Paris has so much interest to the medical visitor as this little island. The day of its medical renown has, however, long since passed away. Handsome hospitals, with ampler appointments, and in better locations, have been erected in the last two centuries, and the old Hôtel Dieu naturally has ceased to serve as pabulum to the ambitious hospital teacher and interne.

The hospital, as it now stands, consists of two buildings, the original one on the island, and a modern one on the left bank of the Seine, the two being connected together by a covered wooden way over the water, and an arched stone way under the Quai de Montebello, running by the river. The original building is the only one of the two we care to concern ourselves about. It has a gable end to the Place du Parvis de Notre Dame, mounted on heavy granite columns; above the roof floats the remnant of a French flag, the blue stripe alone remaining. On the Place the building has two stories, while on the river side there are four. It follows a bend in the river at this point, describing a gentle curve. At the water's edge is a dark, deep archway, guarded by a double gate, and approached by stone steps, leading up from the water for the reception of patients or stores from the river. A description of the appearance of this part of the building is unnecessary. It is enough to note that it is ante-feudal in architectural style; and, were one ignorant of the uses of the old building to which this entrance leads, one might say as well, ante-feudal in its purpose. It suggests the bars and ambuscade and portcullis of the Inquisition. Entering by the main portal on the Place, one finds himself in a large vestibule, where hang oils of Desaut, Bichat, Dupuytren, Thibault, and Moreau. A good bronze bust of Trouseau was placed here in 1867 by subscription. The next rooms in the gabled centre are devoted to amphitheatre, professors, and to the reception of out-of-door patients. The long wards lie on the right of the centre, the left wing being very low, and devoted to laundry and cooking purposes.

A sketch of one ward describes them all. It is about forty yards long, has a width of ten yards, and contains at present on one side thirty, and on the other twenty beds. Some of these are cots stuffed with coarse hair, lying on the floor and occupied by patients. The mounted beds here, as in all the hospital of Paris, are ornamented with curtains, clean and white and stiff enough, but open to comments on the ground of ventilation and as carriers of poison. The bed is a plain iron one, with corner uprights to support the curtains. In the Hôpital de la Pitié and L'Charité I noticed an iron shelf at the head of the bed supported by the two corner uprights, within reach of the patient in a lying position; it is used as a depository of medicine, food, or the carafe of wine. The iron bunk of the Hôtel Dieu is simpler. The ward without modern bathing or water-closet facilities the floor is clean, but not waxed, as in most of the public hospitals of Paris; the exteme wears a long white apron, reaching from the breast to the ankle buttoned behind, and provided between the thigh with a deep, broad pocket for portage of the ware

book and diagnostic instruments. The interne wears the same apron, and usually a black velvet cap, while the chef is recognized by the latter garment alone. To one familiar with the black gown in use in Germany and Austria, this white apron of Paris is a strange novelty; while it fails to add to the dignity of appearance of the wearer, it may be said to increase his fund of *amour propre*; it is, however, suggestive of your garçon at table d'hôte.

On the second floor of one of the hospital buildings is a statue in marble, life size, soiled by the rust of years. I give you the literal translation of its French inscription, as it is the most interesting point of the whole hospital:

"In the year of grace 653, under the reign of King Clovis II., St. Landry, Bishop of Paris, caused to be constructed near the cathedral the hospital of the Hôtel Dieu, and maintained there the poor by his own fortune."

Fastened to the wall of the same room are several dark marbles, bearing titles of ordinances of different kings of France, who in different ways rendered aid to the hospital. Among them are quoted the following:

Philippe Auguste, 1208; Louis neuf, 1269; Philippe le Long, 1320; Charles le Bel, 1324; Henry II., 1554; Henry III., 1582; Henry IV., 1598; Louis XIII., 1614; Louis XIV., 1652; Louis XV., 1719; and Louis XVI., 1781.

On the left bank of the river, and behind the more modern portion of the Hôtel Dieu alluded to, is a very old-looking chapel, which is still devoted to the use of the patients of the hospital. One enters by a side-door into a small auditorium divided into a nave and two side-chapelettes. The chancel is amply but cheaply furnished; there are sitting and kneeling places; and the floor is of brick tiles. It is evidently not as old as the original hospital, and deserves but a brief sketch. The architecture is plain and mixed. While the gabled-end original building is after the Grecian order, the Roman here predominates. The arches of the broad nave are Roman; those of the narrow chapelettes are old Gothic; the columns are round, and, in fact, there is not a fluted column about any of the parts of the hospital. I allude to this, because the fluted column is very popular in the church and hospital architecture of Paris, even in instances where the material is plaster. The capitals of the columns are Dorian, with isolated leaves in plaster; the windows are high and narrow, of small squares of blue glass, bordered by squares of equal size of red glass, while some of them are arranged precisely *vice versa*; in the chancel window of the latter pattern is a cross made of squares of yellow glass; and in the end wall opposite the chancel is a variegated glass rosette high up between the joists. One fails to discover any dates or inscriptions about the chapel, which is easily explained by the fact that it is simply for the service of poor hospital patients. It cannot have stood longer than three or four centuries, though portions of its foundation indicate a much older style of masonry.

I have been minute in the allusions to the buildings of this venerable pile, as they excite chiefly an historic interest.

The following list of services is bulletined in the vestibule of the main building in the Place du Parvis Notre Dame. The appointments for the year 1877 for the medical staff are MM. Sée, Fauvel, Guéneau de Mussy, Frémy, Hérard, and Olmont; and for the surgical staff for the same time, MM. Richet, Cuseo, and Guérin.

The new Hôtel Dieu will be open for the reception of patients August 1st.

The public lectures of the Ecole de Médecine will close with this month; and the new year will begin November 1st.

The *petites nouvelles* of the journals announce the doctorate of a young Russian lady at the school of medicine after defending her thesis at the close of five years of study.

Prof. Darling, of New York, is attending the examinations at the Royal College of Surgeons, London; Dr. E. C. Seguin is among the Americans registered here.

Yours truly, P.

PARIS, July 26, 1877.

## THE ELASTIC BANDAGE USED TO PRODUCE ANÆSTHESIA IN MINOR AMPUTATIONS.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—Having occasion to amputate a finger at the articulation, between the first and second phalanges, I wound an elastic cord tightly around the member, driving the blood completely before the successive turns of the elastic.

On removing the bandage from the end of the finger to the point at which it was desired to amputate, the sensibility was so much deadened that, by the application of ether spray for a few moments, around in the line of incision, the operation was finished without the patient's knowing when it was done. The stump healed nicely, and although both the extensor and flexor tendons were divided, the patient, by practice, which was insisted upon, can flex and extend the stump readily out of harm's way. The flexion is made through the attachment of the *lumbricalis muscle* in front, the extension through the adhesion by inflammation of the tendon of the *extensor communis digitorum* to the sheath on the dorsum of the first phalanx.

The method is certainly preferable to the more tedious use of general anesthesia, and while I had never seen any commendation of its use to the profession, I suspect it is not a novel process.

JNO. A. WYETH.

## Obituary.

### PROF. ALPHEUS BENNING CROSBY, M.D.

NEW YORK.

THE startling news reaches us that Prof. A. B. Crosby, of this city, died August 10th, from apoplexy, at his country-seat, Hanover, N. H. For a few days previously he had been somewhat ill, but was able to be about, and no concern as to his condition was manifested, either by his friends or himself.

He was born in Gilmanton, N. H., February 14, 1832, and was consequently, at the time of his death, forty-five years of age. He received his academic and medical education at Dartmouth College, under the guidance of his distinguished father, the late Dr. Dixie Crosby. Shortly after his graduation he was appointed lecturer, and afterwards Professor of Anatomy at Dartmouth. About the same time he received a similar appointment in the Medical Department of the University of Vermont. In 1871, he was tendered a Professorship in the Long Island Medical College, which he accepted, and which appointment was soon followed by the Professorship of Anatomy at Belle-

vne Hospital Medical College. During the late rebellion he served as surgeon to a New Hampshire regiment, and while stationed in Virginia met his wife, Miss Mildred Smith, of Virginia, to whom he was devotedly attached, and who, with three children, survives him. Soon after his connection with Bellevue Hospital Medical College, he was appointed Surgeon to Bellevue Hospital, both of which positions are made vacant by his death. Last year he was elected President of the New Hampshire Medical Society, a distinction of which he was very proud, conferred as it was by those of his associates with whom he had labored in his earlier career. As a lecturer he was a success from the start, combining rare descriptive powers with a sparkling and impressive humor. In fact, his reputation as a teacher and surgeon, although deservedly great, was scarcely equal to his social popularity, for he was one of the most genial of men. There was cheerfulness in his very presence; his conversation abounded in the richest humor, and when called upon on convivial occasions to respond to a toast, he never lacked for a droll story.

Professor Crosby's library contributions were mostly on surgical subjects, either as papers read before the several medical societies of which he was a member, or as contributions to medical journals. His first paper after coming to New York was upon the case of removal of scapula and clavicle by his father, the first of its kind on record. In his description of the operation, and other details, he manifested a reverential affection for his father's memory worthy of himself and his subject. Exceedingly frank and friendly himself, he naturally had hosts of friends, who respected him for his many rare abilities, and who loved him for himself. With such his loss is irreparable.

His funeral, which was largely attended, took place on Sunday, August 12th, at Hanover, N. H., where his remains were interred.

### ARMY NEWS.

*Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from August 5 to August 11, 1877.*

CAMPBELL, JNO., Major and Surgeon. Leave of absence extended twenty days. S. O. 178, Div. of the Atlantic, Aug. 10, 1877.

TURBILL, H. S., First Lieut. and Asst. Surgeon. Leave of absence extended three months. S. O. 168, A. G. O., Aug. 8, 1877.

### Medical Items and News.

CONTAGIOUS DISEASES.—Comparative statement of cases of Contagious Disease reported to the Sanitary Bureau, Health Department, for the two weeks ending August 11, 1877.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-Spinal Meningitis.	Measles.	Diphtheria.	Small-pox.

Aug. 11.....	0	13	48	3	28	18	0

ROOFLESS THEATRES.—The *Lancet* advocates roofless theatres for better ventilation.

PRIVATE LUNATIC ASYLUMS.—Considerable discussion has taken place in Great Britain regarding the right of persons to care for lunatics in private houses. Notwithstanding it is acknowledged that public asylums are better, the Englishman's idea of his private "castle" overcomes all conscientious scruples.

A CASE OF ASPHYXIA FROM COAL GAS—RECOVERY.—C. J. Cleborne, M.D., Surgeon to Naval Hospital, Portsmouth, writes: "On the 20th of September, 1876, a man descended into a well fourteen feet deep in the gas-house of the Navy Yard at Kittery, Maine, for the purpose of making repairs upon a six-inch pipe, and while employed in unscrewing the valve he was instantly suffocated by the issue of a volume of freshly made gas. Fortunately he was seen to fall by a fellow-workman; and as it was considered dangerous to go down into the well, he was fished for with an iron hook attached to a rope which happened to be at hand.

"When about half way up the man's pantaloons (in which the hook had caught) broke, and he fell, head foremost, into a layer of pitch or coal tar some two or three inches deep at the bottom of the well. No time was lost in rehooking him this time fortunately in his "wooden leg," and he was brought to the surface apparently dead.

"Sylvester's method of inflation was immediately used, and I soon had the satisfaction of seeing the man restored to consciousness. No untoward result followed beyond a smart attack of bronchitis, caused by the irritant action of the gas.

"Perhaps the unintentional performance of Nélaton's inversion method—the man falling head downwards, and remaining in that position until he was brought to the surface—may have been the means of saving his life."

DR. L. A. SAYRE, of this city, is entertaining the medical public of Great Britain with his description of the plaster-of-Paris treatment for spinal curvature.

THE SIZE OF LONDON.—London, the greatest city the world ever saw, covers, within a fifteen-mile radius of Charing Cross, nearly 700 square miles. It numbers more than 4,000,000 inhabitants. It comprises 100,000 foreigners from every quarter of the globe. It contains more Roman Catholics than Rome itself; more Jews than the whole of Palestine; more Irish than Dublin; more Scotchmen than Edinburgh; more Welshmen than Cardiff. It has a birth in it every five minutes, and a death in it every eight minutes; has seven accidents every day in its 7,000 miles of streets; has 123 persons every day, and 45,000 annually, added to its population; has 117,000 habitual criminals on its police register; has 23,000 prostitutes; has as many public-houses as would, if placed side by side, stretch from Charing Cross to Ports mouth; has 38,000 drunkards annually brought before its magistrates; has as many paupers as would more than fill every house in Brighton; has 60 miles of open shops every Sunday; and has an influence on the world represented by the yearly delivery in its postal districts of 238,000,000 letters.—*Med. Press and Circular.*

CONNECTICUT MEDICAL SOCIETY.—This Society has published its yearly volume of Transactions within two months after its meeting. This only shows what can be done by the right sort of Publishing Committee.

SMALL-POX IN LONDON.—The history of the epidemic of last year is to be investigated with the view of more legislation upon the subject.

## Original Communications.

## SOME PRACTICAL POINTS IN THE TREATMENT OF STONE IN THE BLADDER.

WITH AN ANALYSIS OF EIGHT NEW CASES.\*

By JOHN W. S. GOULEY, M.D.,

PROFESSOR OF DISEASES OF THE GENITO-URINARY SYSTEM IN THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF NEW YORK; SURGEON TO BELLEVUE HOSPITAL, ETC.

My main object in presenting this short paper to the Society is to elicit discussion and criticism from our fellow-members and delegates, that we may all enjoy the benefit of their opinions and experiences on a subject which is always interesting and important to practitioners of our art. With this in view, I propose to sketch out a few practical points in the management of stone in the bladder, about each of which I am desirous of obtaining additional light. They relate to exploration of the bladder, to the selection of operation, and to the after-treatment.

I have added to this an analysis of eight cases operated upon since my first report.

## I.—EXPLORATION OF THE BLADDER.

In a paper read last year, I called the Society's attention to the importance of detecting stone in the bladder during the early period of its formation, and to the influence that such early detection exercises upon the selection of the operation. I have now only to add a few facts relating to certain details of vesical exploration. The uncertainty of the information obtained by the use of sounds of large curve in the examination of the bladder, led Civiale and others to employ a light lithotriptor for the double purpose of sounding for and of measuring the stone. But sometimes a very small stone or a fragment will not at first be felt. In that case Brodie suggested that all search be stopped, and that the jaws of the lithotrite be simply opened, while the female blade is kept close to the *bas-fond*, when, after sharply striking the handle with the fingers of the right hand, the stone or fragment will fall within the grasp of the instrument to be measured or crushed. Afterwards Mercier constructed his sound with a short, elbowed beak and long shaft. This sound has been variously modified, but the principle remains the same. The object of this form of beak is to enable the operator to turn it in several directions and examine every accessible part of the bladder. He has since made a hollow stone-searcher on the same general plan, but much larger at the extremity of the beak, which is flattened laterally so as to present a very broad surface, in the centre of which, on each side, is a cup-shaped depression, through which an eye has been cut. By this arrangement the urethral mucous membrane is protected from the eyes of the instrument, which can perform the office of catheter as well as of sound. With this searcher it is much easier to detect small stones than with the former.

While the instrument is in the bladder, it is sometimes necessary to diminish or to increase the quantity of fluid. For this purpose, the stopper at the distal end of the hollow sound is removed and the urine allowed to flow, or the nozzle of a syringe is inserted and warm water thrown in.

Position of the patient in sounding for stone has its importance, and every imaginable posture has been made use of in obscure cases. For examination in the recumbent posture, Reliquet, of Paris, has contrived a very ingenious portable apparatus which can be used on any bed, and by which the pelvis can be elevated and tilted to one side or the other. I have lately used this apparatus in several instances, and consider it of material aid in exploring the bladder and in performing lithotripsy, especially in cases where there exists prostatic hypertrophy and a deep vesical *bas-fond*.

## II.—SELECTION OF OPERATION.

In the management of cases of vesical stones, as in that of other surgical ailments, the exercise of sound judgment is quite as important as the highest degree of operative skill, and the two should go hand in hand. It seems to me unwise to rely entirely upon any single method of treatment or of operation, for in reality there is no exclusively *best* method in surgery, no particular one that should be used in all cases even of a kind. It is often said, and perhaps with much truth, of surgeons who have some pet operation, that they select their cases for this operation and reject all others that appear unfit for it, or even unpromising.

Judicious surgeons ride no hobby, but select, from among the many known operative procedures, that which, after due consideration and study of each case, is likely to be indicated. Some authorities take the ground that the operator should select the operation with which he is most familiar. They speak of excellent lithotomists who are bad lithotriptists, and *vice versa*. Can this be called sound teaching? Suppose, in a certain case, the particular operation of the one-operation surgeon to be contra-indicated, could any but the worst result be anticipated? The one-operation man may be an excellent operator, but very unsuccessful with his one operation, and many of his patients die, while another surgeon, who may not operate so brilliantly, but makes a proper selection of operation, cures nearly all his cases. Is not every surgeon who wishes to treat calculous patients in duty bound to labor hard and long to familiarize himself with all the known methods, and if he cannot master them all, is he justified in undertaking any? If he acts in accordance with the principles of sound surgery, he cannot be a pure lithotomist, lithotriptist, or perineal lithotritist, nor can he even have any particular hobby in lithotomy regarding one method or another, but is competent to choose the operation which appears, after mature consideration, most suitable to the case. We all know that one patient will bear immediate surgical operation, be it lithotomy or lithotripsy, while another of the same age, and, on a superficial examination, apparently in the same state, will be killed by precisely the same treatment as that resorted to in the first case, whereas a few days of rest and other preparatory treatment would have insured success. Is it not better to prepare all cases for operation? Sound judgment and experience, I will repeat, are the only guides in such circumstances.

While I believe that lithotripsy should be the general operation in adults under certain conditions, I am equally firm in my belief that neither this nor any other method will ever become universal, even in adults alone. There will always be a large class of cases in which lithotripsy will be indicated; there will always be cases which will require the knife; there will always be many calculous patients under ten years of age, the majority of which will be cut; there will always be large stones requiring a combination of the cutting and crushing operations; and there will always

\* Read before the Medical Society of the State of New York, June, 1877.

be cases of troublesome calculous cystitis demanding a free incision of the neck of the bladder, even if the stone be small.

These ideas may be formulated thus :

1st. There is no best method of operation or of treatment.

2d. All the operations are good where they are indicated, and bad where they are not.

3d. The operation should be selected for the case, and not the case for the operation.

Permit me to illustrate further some of these thoughts by placing in parallel two widely differing cases: A patient of middle age has in his bladder a stone of not more than three-fourths of an inch in diameter, which is causing cystitis with inordinate vesical and urethral irritability and general neurosis. Each catheterism is followed by alarming rigors and other bad symptoms. If in this case all available means of medical and topical treatment fail to control these untoward symptoms, lithotripsy would be decidedly contra-indicated, and if performed might even prove fatal, while some method of perineal cystotomy, by at once relieving the bladder of the foreign body, and affording free drainage to the inflamed organ, would be eminently successful.

Again, an elderly man, with enlarged prostate, has been under observation for some time, and has declined to submit to an examination for stone, because he will not believe that the slight symptoms which he has so long been experiencing can depend upon the presence of a stone, but he finally yields to the advice of his surgeon, who, after having drawn off a few ounces of residual urine loaded with slimy pus, tells him that as the slime will not for some hours accumulate sufficiently in the bladder to protect it from the stone, his symptoms will be aggravated, and that the next urine passed will probably be bloody. All this he of course doubts until it is realized, and then he is ready and anxious for the exploration, which reveals a stone one inch and a half in mean diameter. The patient is in excellent moral and physical condition, the urethra is ample, and the bladder tolerant. The course of preparatory treatment is short, and the stone is readily grasped by the lithotrite, under which it easily crumbles, and a cure is effected after six or seven sittings, not an untoward symptom having occurred. In this case any method of lithotomy would have been much more dangerous.

The selection of operation for stone is now made by many out of these three procedures, namely, lithotripsy, lithotomy, perineal lithotripsy.

Each operation, as before said, has its particular indication: where one is indicated the others are not.

The indications for lithotripsy are so clear to the surgical mind that it would be needless for me to speak of them on this occasion. But at the risk of repeating myself too much, I must protest against the exclusive use of any one method of lithotomy, even when lithotomy is indicated.

Median lithotomy is advocated, and properly, too, by many of us, in the majority of children; but we know that among these children there will always be some cases which will require incision of the vesical neck, and this is indicated in cystitis with great irritability, and the frequent passage of slimy urine. The same may be said of adults.

I shall leave you to discuss the respective merits of the several other cutting operations.

Let me now recall the Society's attention to the very great importance of fragmentation of large stones in lithotomy, as there are still too many surgeons who incur the risk of removing such stones entire. The

laceration of the vesical neck and prostate, which occurs during violent extraction of a large stone, is known to be one of the most frequent causes of mortality in lithotomy, and strange as it may seem, the practice of forcible extraction is still current. The combination of lithotomy and lithotripsy, designed to obviate this forcible extraction, though insisted upon by Malgaigne, many years ago, was little practised until the last decade, when it was revived and greatly improved by the late Professor Dolbeau, of Paris, who has made of it practically a new operation, to which he has given the name of perineal lithotripsy.

Dolbeau advises dilatation rather than incision of the prostate, and this is wise, particularly in old men; but the essential features of the operation are the breaking up of the large stone and the extraction of all the fragments through a small perineal wound at a single sitting. I feel confident that this method will give better results than have ever been obtained by others in cases of large vesical stones.

### III.—THE AFTER-TREATMENT.

The mere removal of a stone by any operation is often insufficient to cure the existing cystitis. Drainage of the bladder for six weeks or more after perineal cystotomy will generally so relieve great vesical irritability that the wound may be allowed to close, but then there is need of further treatment to complete the cure.

A large class of cases of calculous cystitis are curable by median lithotomy, and by perineal lithotripsy, followed by vesical irrigations. There are many cases treated by lithotripsy in which the cystitis continues for a long period; and the opponents of the operation are too ready to attribute it to lithotripsy, losing sight of the fact that this inflammatory condition had existed long before the operation, which has often greatly mitigated and rendered it much more controllable.

One of the reasons for the continuance of this cystitis is neglect of after-treatment. The French often begin to treat the cystitis before operating, and continue the treatment after the operation until all traces of inflammation disappear. Stagnation of urine is of very common occurrence in calculous cystitis; patients seldom completely empty the bladder before or after some of the operations for stone, and as long as there is stagnation, even only to a small fraction of an ounce, cystitis will continue, and in a few months may become obstinate, and even give rise to a phosphatic stone. Of late the English have adopted the French practice of constantly withdrawing the residual urine, and of beginning vesical irrigation immediately after lithotripsy.

Many of us in this country now make it a rule to instruct patients to draw off the last drop of residual urine twice daily, and to irrigate the bladder, and enjoin them to continue this practice until the urine is clear and passed at normal intervals, and tell them besides, that to neglect this is to render themselves liable to the recurrence of stone. In some cases I find it necessary to irrigate the bladder with nitrate of silver solution (weak), and sometimes, according to Guyon's plan, but in the majority tepid water or the borax solution will suffice. An interesting clinical fact, which is frequently overlooked in many cases treated by lithotripsy, is the subsidence of the cystitis after the first sitting; sometimes it is the reverse, but if the stone does not require for its complete destruction more than three sittings, at the end of the third sitting there is scarcely a trace of cystitis perceptible. Notwithstanding this, I think it is well to use the catheter to empty and perhaps to irrigate the bladder.

One of the main points in after-treatment is to guard against the recurrence of stone. Whatever may have been the original cause should, if possible, be removed. If, for instance, the stone has been of diathetic origin, such hygienic rules and medical treatment should be prescribed as the case requires. The existing dyspepsia should be relieved, and the chylo-poietic viscera put, as soon as possible, into their normal condition. In addition to attention to diet, to the functions of the skin, to exercise, etc., I am in the habit of giving a few brisk cathartics, then to prescribe a laxative and alterative pill, after the following formula:

R. Resinæ podophyll ..... gr. v.  
 Ext. fl. ipecacua ..... gr. v.  
 Ext. nux vomic. aleh. .... gr. v.  
 Hydrastina ..... gr. xxx.  
 Leptandrina ..... gr. xx.  
 Ext. colchici acet. .... gr. xx.

M. et div. in pil. xx.  
 S.: One pill every night.

After the patient has taken forty or more of these pills, I order a small dose of Friedrichshalle bitter water, or the Hunyadi Janos every morning half an hour before breakfast, or the following:

Sodæ sulphatis ..... ʒ i.  
 Ammonii chloridi ..... ʒ ss. M.

S.: To be dissolved in a pint of water; dose, one tablespoonful in half a glass of water every morning, half an hour before breakfast. This may be continued for several months. A grain of sulphate of iron may be added to each dose.

ANALYSIS OF EIGHT CASES OF VESICAL STONE.

Since my first report to this Society at its last meeting, eight cases of stone have been treated by me. Of these, one was 3½; one, 35; one, 45; one, 54; three, 62; and one, 64 years of age.

Six cases were treated by lithotripsy (vesical); one by urethral lithotripsy; and one by lithotomy. All of the six cases treated by lithotripsy had had troublesome cystitis for several years before the operation; one had urethral strictures which required dilatation before the operation could be done; and one had severe strictures requiring division. In one the meatus urinarius had to be enlarged by incision. Four were suffering from prostatic enlargement. One had been lithotomized five years, and lithotriptized one year before.

In one case the stones (two) measured three-sixteenths of an inch; in two cases five-eighths of an inch; in two cases, six-eighths of an inch; and in one case exceeded one inch in mean diameter. There was one stone in four cases; there were two stones in one case, and three in one case.

Two of the patients had had three or more attacks of nephritic colic; one had had six attacks; two gave no distinct history of nephritic colic, and in one case it is clear that the concretions were formed in the bladder, and not primarily in the kidney.

In four of the cases the calculous affection was of five or more years' standing.

Each case underwent the customary preparatory treatment.

The bladder was freed from detritus after one sitting in one case; after two sittings in one case; after three sittings in one case; five sittings in two cases; and seven sittings in one case.

One case was followed by a rigor on the day after the third sitting, the others had no rigors.

The time consumed in the sittings varied from one

to five minutes; five-sixths occupied less than five minutes each.

The lithotrite was introduced twice in one sitting, in one case, and in the others the instrument remained in position, and from one to twenty-seven crushings were made.

The intervals between the sittings varied from two to twelve days.

Only one patient in each of two sittings was etherized.

In one case nearly all the detritus had to be withdrawn by an evacuating catheter. The detritus was spontaneously expelled in four cases; and in one case relieved at one sitting the detritus (four grains) came away in the beak of the lithotrite. Impaction of fragments in the urethra occurred once in two cases, and they were readily extracted with Mathieu's forceps; in one of these cases the fragment had to be crushed with the same instrument. The amount of detritus collected varied from 4 to 154 grains. In only two cases the cystitis has continued. These two require constant catheterism on account of inability to empty the bladder.

The seventh case was treated by urethral lithotripsy, and was a man forty-five years old, with a urethral stricture at the peno-scrotal junction, behind which a calculus had been lodged for two weeks, and could not be displaced by the patient. Twice before a small stone had been arrested at the same point in the urethra; the first time the man succeeded in "working it out," but on the second occasion he failed, and the stone was removed after external incision. When I saw him, he was suffering from considerable urethral irritation but not from retention of urine. The stricture was divided, and the stone crushed with Mathieu's alligator forceps, in the jaws of which some detritus was brought out, while the remainder was washed away by the current of urine; most of it was lost, and only two grains preserved. The patient made a good recovery.

The only patient (three and a half years old) that was lithotomized (median operation) died of pyæmia. This was a case of unusual difficulty, on account of a pre-existing false passage, which was first laid open, but it was found impossible, after careful manipulations, to reach the bladder. The completion of the operation was deferred until at least partial obliteration of the false route should take place, but the patient succumbed from pyæmia on the twenty-second day. No autopsy was permitted.

Including twenty-eight operations from my report of last year, my record stands as follows:

Nineteen lithotripsies ..... 1 one death.  
 One urethral lithotripsy ..... 1  
 Eleven lithotomies ..... one death.  
 Five perineal lithotrities ..... one death.

SUPPURATIVE ARTHRITIS FOLLOWING ACUTE RHEUMATISM.

By V. P. GIBNEY, M.D.

THE specimen \* presented is the larger portion of the patella extoliated from the right knee of a German lad nine years of age, who was admitted to the Hospital for the Ruptured and Crippled, March 8, 1877. The point of especial interest centering in the case is the fact that a rheumatic joint resulted in so profuse a suppuration. For acute rheumatism to often be-

\* This specimen was presented at the meeting of the New York Pathological Society, held May 9th, but being accidentally omitted from its proper place in the report is now published in its present form.

come chronic in the adult is not at all uncommon, for it to become chronic in the child is comparatively rare, but when it assumes a suppurative form then an unusual interest attaches to the case and a thorough analysis is demanded.

Whether the rheumatism in this instance was only one stage of the suppurative arthritis, or whether the rheumatism by its specific influence put the system in a favorable condition for the subsequent arthritis on the slightest provocation, is a question the solution of which I confess my inability to reach, and have accordingly brought it before the members for a full expression of opinion.

The history is as follows:

The boy belongs to a family of eight, only one of whom have died, the cause of this death reported as diphtheria. The family history, paternal and maternal, on a pretty thorough examination, is found unexceptionally good, no hereditary diseases being discovered; the hygienic surroundings have been moderately fair, the health during infancy was not good, and a severe attack of pneumonia (from the history given) when he was one and a half years old, was followed within two or three months by a prolonged pertussis. From all these, however, he seemed to recover perfectly, and enjoyed good health uninterruptedly until the beginning of the present year. One day, about the middle of January, he came in from school complaining of a sense of weariness and pains throughout his bones; went to bed feverish, and on the following morning was unable to leave his bed. The joints became painful, began to swell, and within a few days a typical case of acute multiple rheumatic arthritis was present. A physician was in attendance for a week or ten days, convalescence set in, and about eight days after the doctor had discontinued his visits, seventeen days from the invasion, the right knee, which had not up to this time become entirely free from pain and a trifling amount of swelling, suddenly became very much enlarged, violent pain accompanied, and a severe relapse was thought to be imminent. A surgeon was called in, who prescribed rest and evaporating lotions, but a spontaneous opening in a few days gave exit to a large quantity of offensive pus. Emaciation became marked, and on presentation at the hospital his condition was that of a patient well-nigh exhausted from some acute disease. He was totally unable to stand alone, the normal contour of the right knee was completely effaced, the skin was bluish in appearance, the veins engorged and tortuous, while sloughing had taken place around two openings, leaving ugly ill-conditioned ulcers. Motion was preserved, *i. e.*, to as great an extent as the infiltrated periartritic tissues would allow; no pain was elicited on a careful attempt to approximate the articular surfaces, the patella was movable, and in view of all the facts I made a diagnosis of periartthritis consequent on acute rheumatism. The treatment was tonic medication, and simple dressing to the ulcers. I neglected to mention the peculiar expression given to the eyes. Such an expression is difficult to describe, but is just such as one observes in blondes who are decidedly strabismic. The case progressed favorably until March 16th, when the swelling increased, the temperature rose to 103½°, and an additional abscess seemed to locate itself in the popliteal space. This was subsequently evacuated, and nothing of special note was observed till April 21st, when an extensive abscess filled the whole anterior portion of the thigh, a carious bone was seen protruding from the ulcer in prepatellar region; this was seized with a pair of dressing forceps, and the specimen now before you was easily removed.

An apparatus was applied, the pus being first thoroughly evacuated and stimulants freely added to the tonics already being administered.

There is no question now about the joint being involved, and the course pursued by the disease seems clearly shown by the history as recorded, *viz.*, a suppurative periartthritis extending into the joint, necrosis, caries, etc.

The boy is at present in a better condition than the severity of the lesion would seem to warrant. The sac or sacs are being washed out twice daily with a solution of acid. carbolic. ʒi.-Oj., new abscesses are opened by incision as soon as they form, the limb is kept in a semi-extended position, and the prognosis on the whole is by no means as grave as it was a week ago.

### HALLUX VALGUS TREATED BY EXSECTION OF THE METATARSAL BONE.

By G. H. BALLERAY, M.D.,

PATERSON, N. J.

EDWARD F., aged forty-nine, a resident of Port Jervis, and a horse-jockey by occupation, was admitted into St. Joseph's Hospital January 3, 1877, with the following history:

Three years ago a horse stepped on his left foot, causing a severe injury to the metatarso-phalangeal joint of the great toe. The joint became immensely swollen and painful, and in the hope of relieving this condition, a variety of liniments, poultices, ointments, etc., were used. After the subsidence of the acute symptoms the patient found that there was great deformity left, the joints appeared much enlarged, and the great toe was abducted and twisted so that the plantar surface looked towards the outer border of the foot, and that portion of the great toe near the web rested upon the dorsum of the second toe, while its free extremity was drawn up to an angle of about ninety degrees with the foot. He had not been able to wear a boot since the accident, without having removed a sufficient portion of the top to prevent pressure on the great toe, and even then his sufferings were very great when he walked. He had consulted a number of physicians without relief, and he came to the hospital with the intention of having the toe amputated. In the hope of giving relief without sacrificing the toe, I divided the tendon of the extensor proprius pollicis subcutaneously, and strapped the toe to a splint applied to the plantar surface of the foot, having previously brought it down to, as nearly as possible, its normal position. This treatment relieved the deformity to a considerable extent, but did not, of course, do away with the enlargement of the joint, which remained such as to preclude the possibility of wearing a boot without intolerable suffering, nor was the *abduction* relieved completely by the tenotomy, etc. I concluded, therefore, that probably the best thing I could do for the patient would be to "sever the offending member." Having requested my friend, Dr. E. J. Marsh, to view the case with me, he suggested excision of the joint instead of amputation, and referred me to the cases reported by Drs. Hamilton and Rose, of New York, J. H. Pooley, of Yonkers, and A. C. Girard, of U. S. A., and published in the MEDICAL RECORD August 1, 1873, April 15, 1874, January 9th and May 29th, 1875. I decided to act upon the suggestion of Dr. M., and accordingly, on the first day of February I proceeded to perform the operation. An incision down to the bone was made, commencing about three-quarters of an inch below the inner side of

the metatarso-phalangeal articulation, and extending up along the inner border of the metatarsal bone to a point about an inch and three-quarters above the joint; the soft parts were then dissected away from the bone, the ligamentous structures divided, a chain saw passed around the metatarsal bone, and three-quarters of an inch of its distal extremity removed. The soft parts were then brought together with carbolized silk sutures, and a mixture of carbolic acid and Canada balsam (one part to eight) on lint was applied to the wound. I had forgotten to bring an Esmarch's bandage with me, but Dr. Marsh extemporized one from an ordinary bandage and a piece of rubber tubing, which answered the purpose perfectly, rendering the operation *absolutely bloodless*. About one-half of the wound healed by first intention and the remainder by granulation, and the patient left the hospital with a useful and shapely foot, except that the great toe was about half an inch shorter than its fellow. I think that the chain-saw will prove to be a far better instrument for dividing the bone in these cases than either the bone-cutter or Hey's saw. Notwithstanding the unfavorable result in Dr. Pooley's case, which he evidently attributes to the use of Esmarch's bandage, I think that the advantage to be derived from its use in these cases is such that we are not warranted in discarding it, simply because unfavorable results have been known to follow its employment, unless it is conclusively shown that the evil results are *directly attributable* to the use of the bandage.

## GONALGIA, OR HYSTERICAL ARTHRALGIA.

By C. J. CLEBORNE, M.D.

SURGEON U. S. NAVY.

THE peculiar affection, known as "knee-ache," is not uncommon among women of relaxed fibre, and in conditions of general debility in both sexes. It is usually regarded as a form of rheumatic gout or neuralgia; but I have found it as frequently associated with uterine disorders and hysteria as in cases of gouty or rheumatic diathesis.

In some cases the knee only is affected, in others a dull, diffused, aching pain occurs in the wrists, soles of the feet, ankles, heels, and toes. Sometimes the pain is paroxysmal, coming on suddenly during the day or night, lasting a few hours or several days, and is usually accompanied with more or less pain on movement, and tenderness on pressure.

The patient often complains of the "knee giving way" and of a "cracking sensation" in the joint, and persons have even resorted to mechanical appliances under the impression that the knee needed support. Occasionally the joint is found pale, puffy, or swollen, and there may be hyperæmia and hyperæsthesia with change of temperature, and a tendency to cramp of the sural muscles.

In women who have borne children rapidly and whose nervous systems have been broken down, the left leg or knee is most commonly affected, and there is a strong tendency to spasm of the muscles of the lower extremities, with involuntary contraction of the toes, and a peculiar nervous twitching, especially noticeable during sleep. In nearly all these cases anti-rheumatic remedies alone have but little permanent effect, while flying blisters, stimulating embrocations, and lotions are almost useless. The treatment that promises most speedy relief is a milk diet, the mineral onics (with small doses of colchicum in gouty cases), change of air and scene, douching the painful joint

alternately with hot and cold salt or sea water; the use of Chapman's "spinal bags," and last, but not least, covering the affected part with a sheet of thin rubber.

The rapid effect of the latter in some cases is remarkable.

If the knee-joint is affected, a close-fitting kneecap of sheet rubber should be worn at night, and may be removed in the morning, if all pain and weakness has disappeared, or it may be kept on until it induces a decided eruption or irritation of the skin, when it should be removed and the part washed with alcohol or bay rum. The prompt and efficient relief which the sheet rubber has given in several cases of gonalgia which have come under my notice justifies a further trial of its merits in this painful and annoying affection.

## Reports of Hospitals.

### HOSPITAL OF UNIVERSITY OF PENNSYLVANIA.

CLINICS OF WM. PEPPER, M.D.,

PROFESSOR OF CLINICAL MEDICINE IN UNIVERSITY OF PENNSYLVANIA.

(Reported by Samuel M. Miller, M.D.)

#### SPLENIC LEUKÆMIA.

C. L., aged 30, a carter, born in Ireland. Three or four years ago he was a hard drinker. Six weeks ago his abdomen began to swell. His feet have been occasionally swollen. Epistaxis has been frequent. There has been no palpitation or shortness of breath. He passes very little water, but it contains no albumen. Four weeks ago he had an attack of vomiting. There is some bronze discoloration of the skin. A fluctuating impulse and some bulging of the præcordial spaces are evident. There are three ruptures in the line of and near the umbilicus.

The man came before the class for examination on June 2d. On percussion, dullness was developed on the left side, over an ovoid-shaped space, extending from well up in the left hypochondrium across and down to below the level of the umbilicus. There was quite marked humoric resonance over the posterior edge of this region. There was evidently a solid mass slightly free to move in the abdominal cavity; its shape was very characteristic. No fluctuation could be obtained. The liver was carefully examined, and was entirely normal. The intestines were pushed up to the edge of the ribs. The blood, upon examination under the microscope, showed no unusual number of white corpuscles. The heart's action was labored, but there was no murmur. The organ was pushed slightly to the right. There was quite marked ascites. The man was sick-looking, his tongue roughened, appetite poor, and indigestion frequent. He continually complained of flatulence and a feeling of weight in his stomach. His bowels were generally moved three or four times daily. There has occasionally been blood in the faces. There is no history of malaria. Clearly there is a splenic tumor here, with local peritonitis and ascites. The enlargement of the spleen is enormous. The ascites has probably been produced by the local peritonitis or the interruption of the circulation. There is no history of syphilis. The kidneys and liver are not waxey. The man is too young for cancer of the spleen, and primary carcinoma of this organ is most rare. The various symptoms, epistaxis, indigestion, enlargement of the

spleen, and general loss of health and strength—all point towards a splenic leucæmia. This is one of those cases of pseudo-leucocythæmia. The increase of white corpuscles, not present here, is always a matter of stage. The fundamental trouble is a defect in the elaboration of the blood. I have suggested the name *anæmia toxis* (see *Am. Journal of Med. Sciences*, April, 1877) for this group of diseases. The defective elaboration of the vital fluid may be localized in the spleen, lymphatic glands, or marrow of the bones. Each of these may undergo hypertrophy and degeneration.

The treatment of this group of diseases can be only palliative and for the prolongation of life. Rest in bed is generally needed, with careful attention to diet, and avoidance of gastric irritation. Diet should be mainly composed of milk, with lime-water. If there be constipation, mild laxatives and enemata may be used. For the vomiting, iced seltzer-water, chlorodyne, subnitrate of bismuth, and faradization with mild currents, are indicated. Among medicines may be ranked digitalis, alcohol, cod liver oil, iron, phosphorus, and nitrate of silver. Iron may be administered in the form of the tincture of the sesquichloride, in doses of from ℥ xv. to xx. Phosphorus and nitrate of silver are of use for the irritation of the bowels.

It is needless to say that the disease has a necessarily fatal ending.

#### MENOPAUSE.

CASE 1.—M. McE., 51; born in Ireland; has had no children. She stopped menstruating three years ago. Since then she has suffered from a tendency to polysarcia, with vague rheumatic pains running through her body. Her appetite is good; bowels costive. She suffers from pain in the side and back, palpitation, dizziness, flushing of face, and slight shortness of breath. There is no cardiac murmur, and no albuminuria. Her menses have been irregular for the last fifteen years. She has gained fifty pounds in weight, and is very stout.

CASE 2.—J. W., 45; born in Ireland. Has suffered from epistaxis and pain in left side since last summer. Frequent leucorrhœa within last nine months. Menstruation irregular since last summer. Appetite poor; bowels regular. Has been troubled with shortness of breath, palpitation, cough, flushings of face, and occasional pains in head. She has lost both flesh and strength. Lately the epistaxis has ceased. The menses are very rare at present, and last only a few hours at a time. Her youngest child is ten years old.

It will be noted, in considering these two cases, that in one there has been slow cessation of menstruation, good appetite, and marked gain in flesh; while in the other the menses have stopped almost abruptly, and appetite, flesh, and strength have all gone down.

A great many and very various disturbances of health may exhibit themselves in this disease: Losses of blood; disturbances of digestion; marked nervous symptoms; disturbances of circulation; loss of flesh, or the reverse.

Ovulation fixes woman's place in the animal economy. With the act of menstruation is wound up the whole essential character of her system. At the "change of life" we recognize a transformation in woman's moral, emotional, and sexual character. There is no period of life, except that of early childhood, in which such peculiar conditions arise.

Let us consider the symptoms in order.

I. *Hæmorrhages*.—Some mode of establishing an equilibrium is necessitated upon the stoppage of the

natural menstrual flow. The circulatory fluid is in excess and must find some vent, hence piles, copious epistaxis, hæmatemesis, and hæmoptysis as resultants.

II. *Dyspeptic Symptoms*.—These are very varied, troublesome, and hard to relieve. Women at this time are apt to overeat themselves. The same amount of blood-making food is consumed, and less blood is needed. Therefore, we find (1) actual indigestion, or (2) plethora. There is, in the first case, marked predominance of gastric nervous symptoms, such as heartburn, gastralgia and acidity, headache, disturbed vision and pains over the body, paroxysms of neuralgia it may be. Vomiting is not common. Reflex disturbances, such as fixed pains in the head, are usual. The tongue is large and flabby, the liver congested and inactive. The complexion and conjunctiva may be sallow. Eruptions, such as acne, and crops of pimples arise. The bowels are torpid, and so a chronic catarrh of the intestines may be set up. The second set of symptoms are connected—the assimilation of organic matter into the blood. It may add to the mass of blood and develop plethora, or it may form a low grade of tissue and cause obesity. Such persons suffer from a great sense of fulness and pulsation. The vessels of the head and neck beat and throbb, particularly on bending down; there is giddiness and possibly confusion of mind and loss of memory. The pulse is full, hard, sounding, and slow; the urine high colored, and contains an excess of organic matter. There may be oppression of the chest and fulness at the base of the brain. Polysarcia comes on. The woman increases to double her former weight in the course of a few years.

III. *Moral and Emotional Changes*.—Women may become raving maniacs until the balance is restored. They grow nervous, fidgety, petulant, and hard to get on with. They indulge occasionally in the most peculiar and unnatural freaks.

IV. *Disturbances of Circulation*.—Palpitation and functional derangements are common. The pulse is frequent and irregular; there is often violent dyspnea. No valvular murmur or hypertrophy exist.

V. Latent disposition to disease is exceedingly likely to be roused and become evident at this time. This is particularly the case with gout. The lithic acid diathesis is very common in this country, though gout is rare. The nitrogenous matters are only carried to the stage of uric or lithic acid and there circulate in the blood, taking the form of calculi, and being deposited in the glands. All the conditions necessary to the uric acid diathesis are met with in the menopause. Such women are very likely to have gravel in the urine, thickenings about the joints, etc., etc. Other constitutional affections, such as cancer and phthisis, may also make their appearance now.

As regards diagnosis it is only necessary to note the age of the patient, the menstrual irregularities, and the absence of any other cause for her disease.

The prognosis is generally favorable if the proper medicinal, moral, and hygienic treatment be employed. Otherwise softening of the brain, a permanently congested liver, diseases of the heart, and often incurable constitutional affections are the inevitable consequences.

As regards treatment. The diet must be restricted, and all stimulating foods avoided, though the patient may feel weak and indisposed to exertion. Alcohol, organic foods, and fats are to be strictly forbidden. So, also, with butter, meat, and fried foods. What is eaten should be light and digestible. Moral suasion is of essential importance. Explain to the patient the change she is going through, and so gain her confi-

## Progress of Medical Science.

dence. Exercise, fresh air, sunlight, gymnastic pursuits, bathing, and horseback riding are the chief hygienic indications. If the patient be feeble, with a tendency to tuberculous diathesis, be careful how you put her on an exhausting treatment. Where the liver is congested occasional moderate doses of blue pills are of benefit—3-5 grains once every fourteen days. I have seen the most wonderful results obtained under this treatment, especially if there be an excess of lithic acid in the blood, as shown by the red brickdust sediment in the urine. Some patients cannot take blue pills without salivation, so never give more than two grains at a time, followed by a saline. If calomel is not borne, Epsom or Rochelle salts may be substituted. So some bitter waters may be drunk after breakfast. For the nervous symptoms the bromides are the best remedies. Assafoetida and valerian are also useful. I have had very excellent results from two-grain doses of the monobromide of camphor, taken every two hours until ten grains have been ingested. Dry cups, mustard plasters, and blisters are of value as local applications. The symptoms of circulatory disturbances are to be best combated by digitalis. If, however, there be marked plethora, with a heavy, driving pulse, aconite or veratrum viride may be employed. For the indigestion the diet should be carefully studied. Sometimes the alkalies and nervines are needed on account of the peculiar accompanying pains. The following formula is reliable:

R. Acid. hydrocyan. dil. . . . .	gtt. ij.	
Soda bicarb. . . . .	gr. v.	
Tinct. valeriani. . . . .	fl. ʒ ½	
Zingiberis syrapi. . . . .	ʒ. xl.	<i>m(2)</i>
Aque. . . . .	fl. ʒ. iij.	

S. In water three daily.

Lithia, being a fixed alkali and good diuretic, is often employed with advantage. It has a tendency to the elimination of the urates from the blood. The benzoate, carbonate, or citrate of lithia are also employed. Where there is presumably a tendency to the development of some latent constitutional affection it should, if possible, be anticipated and aborted.

## JAUNDICE WITH ITCH.

The attack came on early in July of 1876 with severe vomiting and purging, jaundice of the catarrhal type. There was complete interference, at an early stage of the attack, with the entrance of bile into the bowel. I could not at that time diagnose any enlargement of the liver. Dyspeptic symptoms have been very marked, and constipation prolonged. The urine is very dark. No flesh has been lost. Lately the brownish color of the stools intimates the passage of some bile through the duct. To-day percussion shows an enormous enlargement of the liver—it extends two inches below the margin of the ribs. The enlargement seems to be uniform. The right lobe extends almost down to the umbilicus. Evidently the case is one of chronic congestion. Were it cancer of the liver the enlargement would not be uniform, the man's general health would have failed, there would be much local pain, and the obstruction of bile complete.

The icterus caused by the circulation of the bile acids in the skin is horrible. The man's life is one of almost ceaseless agony. When the itching is at its worst he bites and tears his flesh and rubs himself with sharp sticks and stones.

The only treatment which has given any relief has been the continuous use of small doses of nitrate of silver and Karlsbad waters. Soda-baths have been tried without success. Alcohol, fats, and much sugar must be avoided. The diet should consist of vegetables and a moderate amount of starchy foods.

CHANGES OF THE PUPILS IN CHLOROFORM NARCOSIS.—In the surgical clinic in Göttingen during the past winter, the changes in the pupils during the administration of chloroform were carefully observed in 122 cases. Previous to and during the stage of excitement, the pupils were, in most of the cases, of the usual width; in a few cases, just before the stage of complete insensibility, they were quite wide and sensitive to light. During the stage of complete insensibility they were closely contracted in 120 of the cases, and were absolutely immovable in 119. An instantaneous dilatation of the pupils in this stage was found to be a threatening symptom of chloroform poisoning. This occurred in two of the cases, in one of which the trouble seemed to be located in the heart, and in the other in the lungs; in both, life was restored by pulling forward the jaw and resorting to artificial respiration.

The following practical lesson has been deduced from these observations: When, during the stage of tolerance the pupils begin to dilate slowly, it is a sign that the patient is recovering from the narcosis, and more chloroform must be given; when, on the other hand, the pupils become suddenly widely dilated, the administration of chloroform must be at once stopped, and further trouble guarded against.—*Centralblatt für Chirurgie*, June 23d.

ON INSOMNIA.—M. Willemin, of Vichy, has recently published a paper on insomnia, which terminates with the following conclusions:

1. Morphine is the most powerfully hypnotic alkaloid of opium; narceine and codeine are less active, but do not leave behind the malaise that morphine produces. These substances are indicated in the insomnia of pain; they are counterindicated when cerebral congestion exists.

2. Bromide of potassium, which is a much less powerful hypnotic, is indicated in insomnia with circulatory excitement, such as the nervous insomnia in which opiates often prove inefficacious. It is administered with success to children. It is counterindicated in cases of very marked anemia.

3. Sulphate of quinine, like the bromide, seems to exert an action on the nervous elements, which is followed by diminution of the encephalic congestion; like these two drugs, chloroform, administered by the mouth, proves useful especially in nervous insomnia.

4. Hydrate of chloral is a pure hypnotic, and is more rapid in its action than the others. It is applicable in almost all forms of insomnia, except in certain dyspnoic and cardiac affections, and when great debility exists.

5. The insomnia of old people and of weak, anemic persons may sometimes be combated with success by tonic medication, wine, ether, bitters, and hydropathy.—*Lyon Medical*, June 17th.

A CASE OF ELONGATION OF THE RADIUS.—At a meeting of the *Société des Sciences Médicales* of Lyons, in March, M. Quioe presented a plaster-cast of an arm which had become elongated in consequence of an osteitis of the radius. The patient was a seamstress, 57 years of age, and the deformity was first noticed five years ago, previous to which time both arms had been perfectly alike. She had never received any injury of the arm. At first she had no pain, but after a time the arm began to pain her when sewing, and she was obliged in January last to enter a hospital. Ex-

amination then showed that the two ulnar bones were of equal length; the left radius, measured in a straight line, was four-fifths of an inch longer than the right, and it was moreover bent backwards in its lower half in the form of an arch, with the concavity looking forwards and inwards. The forearm was in a position of complete supination; the hand was slightly flexed, and in a position midway between pronation and supination. The left radius was about a twelfth of an inch thicker than the right. The bone could be easily mapped out with the fingers; the skin over it was normal, and there was no increase in the temperature. The elongated radius was not rugose, and its consistence was the same as that of the right radius. It was slightly tender on pressure, but the patient only complained of pain when she tried to work. There were no enlarged glands in the axilla or near the elbow. The other bones were healthy, and the general condition was good. The patient denied all history of syphilis. Iodide of potassium was administered for two months, but the only effect produced was a slight diminution in the pains, which was probably due, not to the drug, but to the cessation of work. M. Quic regarded the case as one of chronic osteitis, due to excessive fatigue of the hand and forearm. The case is rare, both on account of the increase in length and the absence of softening.—*Lyon Medical*, June 24th.

**ARSENIC IN THE TREATMENT OF MALIGNANT LYMPHOMA.**—In 1871, Prof. Billroth published the history of a well-marked case of multiple lymphoma, which was cured in a short space of time by the internal use of Fowler's solution. Since then he has repeatedly employed the same treatment with the most marked success. Extensive tumors in all parts of the body, complicated by masses of hyperplastic glands as large as a man's head in the thorax and abdomen, have, under the use of arsenic, disappeared entirely, or at least diminished so much in size that the patient was able to return to work. In some cases the treatment had to be continued a year. Prof. Billroth does not deny the value of operative measures in the early stages of the affection, when only a few superficial glands are affected, but even in such cases advises the use of arsenic also, in order to prevent the spread of the disease to other glands. In the later stages of the affection, when the deeply seated glands are involved, an operation is out of the question, and experience has proved that the arsenic treatment is the only one which offers a prospect of saving the life of the patient. Relapses frequently occur, but are speedily arrested by the same treatment.

The arsenic should be given internally, and by parenchymatous injection into the glands at the same time. Five drops of Fowler's solution, with an equal quantity of tincture of iron or of dialysed iron, are to be given morning and evening on a full stomach. Every second or third day the dose is to be increased by one drop, until symptoms of poisoning make their appearance; this usually does not occur until the patient is taking from 25 to 30 drops of Fowler's solution *pro die*. The dose should then be diminished by a drop every second day, but on no account should the arsenic be stopped immediately. Sometimes the symptoms of poisoning do not set in at all, even when 40 drops of the solution are given *pro die*. In Prof. Billroth's wards, the dose is never allowed to exceed this point. For the parenchymatous injections, pure Fowler's solution is to be used, and as a rule only a few drops should be injected in one spot. Two or three injections may be made every day, provided there be no local irritation. When the glands become

inflamed the injections must be discontinued, and moist heat employed. In making the injections, care must be taken to prevent the escape of any of the solution into the subcutaneous areolar tissue, an accident which is betrayed by sudden and intense pain. The injections are sometimes followed by neuralgic pains, which are readily relieved by hot compresses to the painful glands.

Children are much more tolerant of the arsenic than adults. The treatment sometimes causes sleeplessness, restlessness, an excited state of the nervous system, a melancholic condition, etc., all of which disappear as soon as the dose is diminished. Fever is very generally, but not always, present; it may be remittent or intermittent. The latter, in Prof. Billroth's wards, was observed only in patients who were treated by parenchymatous injections, and always set in about an hour after the injection. During every attack of fever, the glandular tumors became noticeably smaller. The fever never occurs in cases in which no diminution in the size of the tumors takes place; in other words, the arsenic fever is simply a resorption fever. Where the arsenious acid has been injected into a gland, a small spot of necrosis is produced. The glands, however, do not show traces of suppuration or of caseous degeneration; hence it is probable that the arsenic in the circulation acts chemically on the lymphoid cells, which undergo such changes as to become capable of being reabsorbed. The destructive influence of the arsenic on the physiological tissues should be counteracted by good food and by alcohol; if the fever become too violent, the doses should be diminished.

The following are the most important conclusions drawn by Dr. Winiwarter, the author of the paper from which the above is taken:

1. The arsenic treatment is efficacious in cases of malignant lymphoma, and also of leucæmia, since it leads to the resorption of the hyperplastic glandular tissue.
2. The good effects of the arsenic are due to its power of inducing in the albuminous tissues, and above all others in the glandular tumors, a destructive process, which prepares them for resorption.
3. The local action of parenchymatous injections, and the arsenic fever assist in producing the diminution in the size of the tumors.—*Allgemeine Med. Cent.-Zeit.* May 16th, 19th, and 23d.

**CASE OF OSSIFICATION OF THE EYEBALL.**—Dr. H. M. Jones, of Cork, recently enucleated an eye which was extensively ossified. On slitting up the sclerotic, this tunic with the cornea peeled off cleanly, the ossified mass turning out like a nut out of its shell. These tunics were somewhat thinned and the cornea was opaque, but otherwise they presented no morbid condition. The lens was adherent to the iris, and merely represented by a tough, gritty membrane of a white color. The pigmented layer of the choroid was much thinned, and was spread out over the bony mass; by careful manipulation it was completely stripped from the latter, being connected with it only by some minute withered vessels, which pierced the osseous structure. The bony globe was open in front, and contained a brownish serous fluid with masses of yellow, caseous material. The remains of the retina were attached to the inner surface of the osseous structure, which, when completely freed from the tissue, resembled in form the empty shell of the echinus. The optic nerve was separated from its retinal expansion no aperture for its passage existing in the bony case.—*Dublin Journal of Medical Science*, July.

# THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, August 25, 1877.

## A PLACE IN WHICH MEDICAL CHARITY IS NOT ABUSED.

In another column will be found a short extract from the letter of a physician in Waterbury, Connecticut, concerning medical charity there. We are informed, in regard to remuneration for pay-patients, that "there are no losses whatever, and no free patients. If any poor patient wishes to apply for dispensary relief, he seeks a selectman," and obtains from him a permit. The town then pays the doctor for his services, and buys the medicine for the patient. It is difficult to understand how anything could be more simple and effective. We are not aware that there is any room for more medical practitioners in Waterbury, but if such should prove to be the case, vacancies can be very easily filled. All that the physician could wish for is a decent sick-rate to make business ordinarily brisk.

While we congratulate our medical friends in Waterbury, we beg them to consider the danger of innovation. It is impossible to say when some of their number may be seized with a desire to found a medical college, teach students, or write a book. When that time comes, clinical material must be had, and the use which can be made of it by the members of the Faculty will be far more valuable to them than any pecuniary return which the town may make for abstract services or necessary medicines. In the course of events may come a demand for a large hospital, and the desire to fill it with patients, and then, if there be not enough positions in hospital and college to satisfy every practitioner, there will be trouble. But let us hope that this will be a long way off.

The admirable provision for the poor in the town named is worthy of the attention of every one really interested in suppressing the ordinary abuses of medical charity. Our correspondent, in his enthusiasm, wishes that some such plan could be adopted in New York City. There are many who share with him in

that hope, but, alas! there are difficulties with which to contend in a large city which amount to nothing in a small town. In the latter, any system of inspection, however simple, can be made sufficiently effective to guard against any flagrant abuses, but in large and mixed populations this is almost impossible. There can be some approach to it, as seen in the efforts of the Association of Out-door Relief in this city, and also in the inspections of the St. John's Guild; but in spite of all the care, persons have been found who receive bread, tea, sugar, and fuel, and who exchange the same with small shopkeepers in their vicinity for intoxicating drinks. In fact, some of these shops do quite a business in that line. Still, this is no reason why we should not try to do all we can in the required direction. There may be more reason to hope for good in the efforts of the Dispensary Association to be formed in this city, and perhaps the Medical Provident Committee may have some extra suggestions to offer, but at all events the necessity for something being done at once is quite urgent. Those gentlemen who, by chance or necessity, have stayed in town during the warmer months, have reaped somewhat of a harvest, but when the colleges begin, when the dispensaries are thronged with students, and when the Out-door Department of the New York Hospital sends out a few more thousands of its circulars, inviting the suffering poor to dollar chances, when the surgeons of the hospitals are looking around for cases upon which they may operate, and upon which they may lecture; then will every practitioner in New York, who has not a hospital, dispensary, or college appointment, envy his brethren of Waterbury, and yearn to settle in their midst.

### THE HEALTH DEPARTMENT.

An article in a recent issue of the *Times* calls attention to the extravagant management of the Health Department of this city, backing up the assertion with the fact that nearly the entire appropriation of over two hundred thousand dollars is used up in paying the salaries of the officials and their supernumeraries. Although we have never believed the Health Board has been as efficient as it might have been, still as a political machine it has done very well. Any other department under similar influences of patronage could not probably show any better record. But this is no good excuse for the army of political "hangers-on" for whom positions must be found. The true responsibility of this state of things rests with the commissioners themselves, who have it in their power to reduce the force of these supernumeraries, so that some margin may be left for the emergencies of extra work. The clerical force is altogether too large, and its work should be shared by some of the more prominent officials, who draw large salaries and do very little work. We have always contended that the Sanitary Inspectors are working-men who more

than earn their salaries. In fact, upon them the true efficiency of the Board depends, and yet their pay is very little more than that of an ordinary clerk, while it is exceeded by that of the chief clerks. The fault lies in the disposition to minister to the claims of political patronage in providing places for small politicians, rather than in overpaying those who do the real work of the Board. But how can this be helped when the President of the Board is confessedly a politician who is said to hold his place chiefly upon the representation of the President of the Board of Aldermen that he is a good Democrat, and has been known "to act with the Democratic party of this city?"

## Correspondence.

### CONCERNING IDIOSYNCRASIES AND PROFESSIONAL RESPONSIBILITY.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—After listening to the medical testimony in, and reading your editorial on, the case of Dr. Westlake, tried in Elizabeth, N. J., for malpractice, in causing the death of young Lewis, who died under the influence of chloroform administered for the extraction of a tooth, the question, "How far is the physician responsible for the effect of medicines prescribed or administered by him?" very naturally and forcibly suggests itself.

In this case, it was proven that Westlake administered chloroform in the way dentists usually do; that the quantity was not large; that the tooth was extracted while the patient was struggling; that the patient was partly conscious after the operation—at least, attempted to spit when told to do so; that immediately after this attempt he passed into an unconscious state, from which he did not revive, and the *post-mortem* showed Lewis to have been a healthy lad.

The prosecution failed to prove that Westlake was incompetent to administer chloroform, or extract teeth. They failed to prove that he was not sober at the time of the accident, and neglected to attempt to prove the only strong point in the case, viz., that he did not resort promptly to the proper method of restoring the suspended action of the heart and lungs.

In the cross-examination, the prosecution admitted that there is such a thing as idiosyncrasy, and that sometimes remedies administered by the most skillful practitioners, with the best possible intentions, produce painful instead of remedial results, and that no physician, however learned or practised, can determine at the time of administration the effect of his most studied and carefully dispensed prescription. Illustrating this peculiar susceptibility of some systems to the influence of certain medicines, the effect of camphor may be mentioned.

This drug was given in the ordinary dose to a patient suffering with colic. Its depressing effects were so marked and serious that the attendants for a time thought the patient dead.

About twelve or fifteen years after, under similar circumstances, the same remedy was administered to the same patient, by the same physician, with results sufficiently distressing to have made me, though only a lad at the time, not only distrustful of even so simple

a drug as camphor, but to gather here and there, as I could, cases where its peculiar effect has been marked and serious.

One of these cases I will here state. A boy, about sixteen years of age, was directed to procure some gum camphor, and with a package of this drug in his pocket, he returned to his home two miles in the country. While unharnessing his horse, he was taken in a fit. He was carried to his bed, and his clothing removed, when he at once revived. When asked if he had ever had a fit before, he said, "Yes," once before, when he took camphor.

Calomel, perhaps as certain in its action as any drug we possess, sometimes produces effects altogether at variance with our wishes. As an example: ten grains were given to a stout and ordinarily healthy lady, aged twenty, who seemed to have a mild remittent. It had no cathartic effect, and instead of the ordinary discharge of ptyalism, every attempt to eat or swallow brought on a profuse discharge of dark, watery, offensive blood from the gums.

In addition to this, there was a continuous uterine hemorrhage, in character much like that above described, which no remedies seemed to control.

This condition lasted about four weeks, indeed till her life was despaired of, and, judging from her looks, one might have supposed that the hemorrhage ceased only because there was no more blood to flow.

A few years ago, one of the most eminent surgeons in your city was called in consultation to see a lady, aged fifty, who had been in delicate health for a year or more, and whose abdomen had a hard, nodulated feel. After a careful examination, he concluded that the abnormal condition was due to an accumulation of hardened feces, and he assured her that, to the best of his judgment, she would be entirely relieved in a few days. He directed two generous doses of blue-mass, followed by sal Rochelle. The effect of the cathartic was only limited by death, which occurred on the third day after taking it. The examination after death showed the abnormal condition to be a cancerous deposit in the omentum, and not hardened feces in the bowels.

The prescription was directed after hearing a full history of the case, and after giving the patient a careful examination. The result shows that the cathartic hastened the final issue, and that it was exactly the medicine she should not have had.

In one of your late numbers, you give the report of a death from the "absolutely safe anæsthetic nitrous oxide." The unfortunate patient being a surgeon of considerable repute, most likely every precaution was taken to administer it carefully.

Now, the patients who had chloroform and nitrous oxide undoubtedly died from the effects of these anæsthetics. The cathartic was certainly the immediate cause of death in the one who took it, for her decline had scarcely been perceptible, and under a tonic treatment she had apparently improved, and seemed as well the day she had blue-mass as at any time in two months. The patients who had camphor and calomel suffered less from the effect of these drugs only in the result.

These cases are not offered as an excuse for the dentist, nor as a criticism on the administration of the other mentioned drugs, but to show that no medical man can count with certainty on the effects of his prescriptions, any more than the surgeon can explain how one patient receives a fatal shock from an operation or injury while another apparently receives no shock from a like misfortune.

H. H. J.

RAHWAY, N. J., July 4, 1877.

ON THE GENERATION OF BACTERIA IN URINE.

By FRANCIS GERRY FAIRFIELD.

I DESIRE, as a medical student, to lay before the readers of THE MEDICAL RECORD the results of a series of experiments that have an important bearing upon the origin of bacteria and vibrios in diseased tissues. The inference, for example, is a fair one, that if an experimenter were to introduce through a catheter a small quantity of liquor potassa in the living bladder, and to detain it there for thirty-six hours, the result would be an abundant generation of bacteria in the urine thus detained—in other words, an artificially produced diphtheria of the bladder.

It is not my intention in what follows to venture upon any discussion of the varied experiments that have been instituted of late years, with a view to settle the still-contested issue whether, under favorable circumstances, minute organisms may be developed in vegetable or animal infusions without the presence of antecedent germs. In England, Professors Huxley, Tyndall, and Bastian; in France, M. Pasteur and others; in Germany, Cohn, Hueckel, and Dollinger; in this country, Professors Wyman and Clarke, of Harvard College, and other eminent microscopists, have all contributed important memoirs to the literature of spontaneous generation, the third in order and the last two having taken decided ground in favor of abiogenesis, and the rest more or less decided ground against it. The latest aspect of the subject, and one that has revived the controversy in all its virulence, is presented by a series of experiments recently instituted by Dr. Bastian, in England, and repeated and verified by the eminent M. Pasteur. As my own experiments, conducted after Bastian and Pasteur, have been attended with surer results than they record—results that appear to me to settle the question at issue with an unanticipated certainty—I shall first detail them with all possible brevity consistent with sufficient exactness, and then indicate the conclusions to which they have inevitably forced me.

Tuesday, April 10th, at 12 o'clock, noon.—Having first carefully tested three bottles, each of the capacity of four ounces, with absolute alcohol, they were immersed for ten minutes in boiling water, 241° F. On removing No. 1 from the water it was instantly filled with urine transferred, without coming in contact with the external air, directly from the bladder of a healthy male, and liquor potassa at the temperature of 221° F. was added in a sufficient quantity for neutralizing the excretion. The bottle was then stoppered with a rubber stopper taken from the boiling water, the liquid overflowing as the stopper was pressed in, so that not a single bubble of air remained. It was next dipped to the shoulder in melted wax, and thus hermetically sealed. Finally a filter of cotton batting was drawn over the stoppered end and tied securely in its place, and the whole protected with a tightly fitting rubber cot descending to the shoulder. The operation took exactly four minutes and thirty-seven seconds.

On removing bottle No. 2 from the water it was instantly filled with urine at a temperature of 236½ by an accurately graduated medical thermometer, liquor potassa at 221½° being added for neutralizing, and stoppered in exactly the same manner, with the addition of cotton filter and rubber over-shield. No. 3 was filled under the same conditions with urine and potassa, and corked with an ordinary cork. Without any precautions whatever, two two-ounce test-tubes were then filled, the one with boiled, the other with

untreated urine, sufficient potassa added to each, and placed open in the test-tube rack. The urine was all drawn from the same person, and the specimens were all placed on the mantel. The temperature in my room during the experimental thirty-six hours following varied from 73 to 77° F.

April 11th, at 11 o'clock p.m.—Having prepared five slides with cells constructed by removing from inch-square sections of tinfoil a central disk one-half an inch in diameter and then cementing the sections to the surface of the slides, I cleaned five inch-square covers. On test with dropping tube the capacity of one of these cells was exactly one drop. The examinations were conducted with a ¼ inch objective, giving with C eyepiece, tube drawn, 1,250 diameters. Opening bottle No. 1, which was thoroughly shaken at the instant of unstopping, I commenced my examinations at midnight, by transferring a single drop to one of the cells, covering it, and searching it field by field, with the stage of the microscope adjusted to an exact level. The drop was absolutely swarming with minute forms of life, among which the most numerous were cylinder-like bodies about 1/1000 of an inch long, and 1/2000 of an inch in diameter. A few specimens of the familiar bacterium termo, an occasional moniliform vibrio, and monads only less in number than the bacilli, presented themselves as field after field was gone over with. Counted ten fields in ten consecutive drops, and registered the result of each field. The total count for 100 fields was 591. No. 2 yielded under the same count 67 organisms to 100 fields. No. 3, as to which no special precautions were taken, 289 in all to 100 fields. Test-tube No 1 gave 227 to 100 fields; test-tube No 2, unboiled, 608 to 100 fields. Now, as the actual diameter of the field with C eyepiece, tube drawn, measured by Nobert's rulings, was almost exactly 1/1000 of an inch, and as the cell was half an inch in diameter, the number of such fields contained within its area was  $\frac{1,000 \times 1,000}{2 \times 2} =$

250,000; upon which basis the number of organisms to the ounce in each specimen may be readily calculated, counting, as is the case with our more delicate dropping-tubes, about 500 drops per ounce.

	Per drop.	Per ounce.
Bottle No. 1 . . . . .	1,477,500	737,750,000
Bottle No. 2 . . . . .	167,500	83,750,000
Bottle No. 3 . . . . .	722,500	361,250,000
Tube No. 1 . . . . .	567,500	283,750,000
Tube No. 2 . . . . .	1,520,000	760,000,000

Transferred one-eighth of an ounce from bottle No. 1 to a blue glass culture camera, and re-examined it at the expiration of twenty-four hours. The number of bacteria had considerably diminished, but the field was studded with large celloform germs, with bacterium colonies densely packed together and apparently dead, and presented an extraordinary fungous development, which evidences that some of these low forms of life are animal only in their earlier stages.

Thursday, April 12th, 12 m.—Repeated the preceding experiments with specimens of healthy urine, all obtained from one person, not the same as in the first series.

Friday, 12 o'clock, midnight.—Commenced a series of examinations as before, and finished at 7 o'clock Saturday morning, with the following tabular result:

	Per drop.	Per ounce.
Fresh urine, unboiled . . . . .	1,022,500	511,250,000
Urine boiled . . . . .	130,000	65,000,000
Same, without precautions. . . . .	590,000	295,000,000
Open tube, boiled . . . . .	527,000	263,500,000
Same, unboiled . . . . .	1,817,500	908,750,000

Monday, April 16th, 12 M.—Prepared two bottles of urine from a patient in advanced stages of Bright's disease of the kidneys, in exactly the same manner as Nos. 1 and 2 in the first series of experiments. Result per 100 fields, at the expiration of thirty-six hours, 832 for fresh, and 244 for boiled urine—not so large an advance upon the results obtained from the healthy excretion as I had anticipated.

The extraordinary fact that appears in experiments conducted with urine consists in the almost inconceivable number of organisms developed, and in the tremendous rapidity of the process, which, on comparing the results from bottle No 1 with those from tube No. 2, are neither accelerated nor diminished materially by the exclusion or presence of free oxygen. Another curious fact is that in every instance the slight cloudiness denoting the appearance and progress of vital phenomena commenced at the bottom of the bottle or tube and slowly involved the upper strata of the liquid. Now, the specific gravity of liquor potassa is a little greater than that of urine. Consequently, upon its addition to the specimen, the formation of urate of potash crystals commences at the bottom of the vessel. In such case I added potassa until a few crystals appeared, and then, after stoppering, shook the specimen. The development of the cloud invariably commenced within thirteen hours after the addition of the potassa, and proceeded from below upwards until the liquid was slightly opaque and had a whitish lustre from top to bottom, the opacity predominating beneath. Now, taking into account the fact that the life-term of a bacterium must be reckoned at from twelve to fifteen hours, and that the transformation of bacteria into fungous developments is evident, at least as respects some of their varieties, it is not only practically, but absolutely impossible to explain the tremendous number of organisms in bottle No. 1, or even in No 2, by assuming that a few germs previously floating in the atmosphere may have passed through the rubber hood, the filter of cotton, the sealing of wax, and the rubber stopper, and infected the contents beneath. Assuming such germs to be the products of pre-existing bacteria, as every microscopist is aware, such organisms are too rarely met with to account for such a myriad development within thirty-six hours, even in an open vessel. If, as is certain as concerns some species of the bacterium—the bacterium termo, for example—such minute organisms are stages in the development of microscopic fungi, then their germs can be identified at a high power. Now, not with a view to a demonstration on this point, but in order to determine, if possible, the effect of dirty streets on the condition of the atmosphere, I had previously conducted and recorded a very simple series of experiments, by spreading drops of balsam upon slides and leaving them exposed to the air upon the mantel for forty-eight hours. In no instance, in the many experiments so conducted, have I ever found more than a dozen identifiable germs of any class to have settled upon a circle half an inch in diameter in forty-eight hours; so that, in whatever light one views the problem, the hypothesis of organizable matter introduced from without is inadmissible—more than that, absurd and impossible. The conclusion must be, then, that such organizable matter was present in the urine when it was withdrawn from the human body, and that, as a factor in their development, contact with the atmosphere was of no practical importance; and yet during a practice of years in medical microscopy, having studied more than 3,000 specimens of urine in conditions of health and disease, I have detected now and then, but very seldom on the whole, a few specimens of bacteria

and possibly a few micrococci, such as are found occasionally in ulcers and abscesses. On one occasion, after permitting a mouse to putrefy under a bell-glass, I found abundant bacteria in sections of the putrescent brain, and abundant vibrios in sections of muscle. I doubt whether atmospheric germs were materially concerned even in this case. On the contrary, it is pretty clear from all the facts that these minute organisms are simple products of putrefaction, and nothing more than that. Moisture and temperature have a perceptible influence in hastening their development, but in other respects the external conditions are unimportant. How minute such germs must be, if such organisms spring from them, is evidenced by this fact: With  $\frac{1}{16}$  inch objective, using a C eyepiece, giving, with tube drawn, 2,100 diameters, my eye could not fail to detect and appreciate an organic particle  $\frac{1}{100,000}$  of an inch in diameter, while the minutest micrococci I have ever observed, in specimens of the saliva of a rabid dog, are not less than  $\frac{1}{200,000}$  of an inch, and the spirilla in active vaccine, animal germs most likely, are somewhat larger than that. Some vibrios—and probably all in their earlier stages—are simple strings of minute granules about  $\frac{1}{300,000}$  of an inch in diameter. Now, my own observations lead me to believe that these minute granules are spontaneous developments of decomposition, produced by a series of molecular changes in the decomposing tissue or infusion. It is possible—probable, even—that the decomposition of a tissue or an animal or vegetable infusion disengages millions of organic molecules which are capable, under favorable conditions, of producing such lower forms of life as monads, bacteria, and vibrios, and that our bodies are thus in themselves billions upon billions of possible minute organisms. In a word, the specimens of urine under experiment contained millions of organic molecules, to which the potassa supplied the essential condition for development into forms of life appreciable by the microscope.

On Monday, April 16th, examined the contents of an hermetically sealed culture cell, in which a couple of drops from specimen No. 1 had been growing since the date of opening the bottle. A few monads and bacteria were visible in the field by a one-eighth inch glass; but the greater part of the urea was occupied by a fungous growth, amid the meshes of which were scores of amebæ in rapid motion. On searching the specimen more carefully I found three fully developed animalcules of a species entirely unfamiliar to me, not moving by means of vibrating cilia, but by alternate expansion and contraction. This one experiment demonstrates nothing, I confess; but it suggests that monads and bacteria are but stages in a development of life that passes from them into a vegetable form, and finally terminates in the ameba and the higher animalcules.

May 27th.—Since the foregoing observations were prepared, a case has come under my notice which curiously illustrates one of the points at issue. Miss J. K., of this city, tolerably healthy in appearance; not at all exsanguinated; persistent pain in the frontal region; relish for food rather increased than impaired; considerable swelling of the joints. Has had severe attacks of dyspepsia, and is an invalid of several years' standing. Attended by Dr. Comstock, 83 Lexington Avenue; case recently diagnosed, Dr. Comstock tells me, by Dr. Flint, as one of Bright's disease of the kidneys. Specimen of morning urine examined May 29d, from six to seven hours after evacuation. Specific gravity normal; deficiency of uric acid and urea; sediment after heating abundant in mucous and epithelial debris. No casts; reaction

neutral. So extraordinary was the development of bacteria in this specimen, that, within the field of a one-fourth inch objective—field  $\frac{1}{4}$  of an inch in diameter by micrometer measurement—they actually swarmed by the hundred. Counted six fields, with the result of 121, 132, 101, 147, 103, and 159. Dr. Comstock had previously diagnosed rheumatic arthritis—a diagnosis rather militated against by the conspicuous deficiency in uric acid and urea. Suspecting mesenteric disease, there being no history of syphilis, I suggested hyposulphite of soda in fifteen to twenty grain doses, twenty minutes before eating. Examined a second specimen this evening (May 27th). Same general description, with the exception that the bacteria are lying dead under the glass by hundreds, instead of being in active motion as before. Dr. Comstock reports that the patient is mending under the exhibition of the hyposulphite. The curious fact here is that there have been no symptoms of diphtheria of the bladder, as would naturally follow from the bacterial theory of diphtheria. As it happened, on the same evening, May 27th, an opportunity to examine some fresh sections of diphtherial membrane occurred in the case of a boy, five or six years old, brought in for examination. The membranous structure of the sections was well marked, and numerous fungous spores and cells, as well as filaments, were visible, but not a single bacterium appeared. Is it not possible that the bacteria noticed by foreign observers may have been accidental products, not concerned in the causation of the disease? I have met them sometimes in saliva taken from the mouths of rabid dogs immediately after death, but only twice in eleven examinations during the last four years, while a well-marked vegetation that I will take the liberty of styling the *Penicillium rabiei canino*, has been unfailingly present in great abundance.

### MEDICAL CHARITY AND THE TOWN OF WATERBURY, CONN.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—This is the way in which they manage "these things" in the town of Waterbury, Conn., and I think you will admit that the following subjoined extract from the letter of a physician in Waterbury to a medical friend in this city is worthy of more than a passing thought:

"There are no losses, however, as *all* the bills are paid, and there are no free patients. The poor of the town are admirably provided for, and I wish some such plan could be adopted in New York City. When a patient wishes to avail himself of the Dispensary, he is obliged to apply to one of the 'Selectmen' for a recommendation. If the Selectman is not satisfied as to the applicant's poverty, the application is *refused*. When, however, the case is genuine, the Selectman gives the patient a ticket of admission to the Dispensary, and the *town* pays the doctor and buys the medicine; consequently, Waterbury neither manufactures paupers nor starves its doctors. . . . The people seem not only grateful for what is done for them, but also anxious to settle their bills."

Respectfully, VIATOR.

HYDROPHOBIA.—Hydrophobia is on the increase in London, and the dogs run around loose in the streets seeking whom they may bite. This condition of things is contrasted with the excellent regulations said to exist with reference to truant dogs in this city. But this is more a matter of imagination than reality.

### New Instruments.

#### APPARATUS FOR TREATMENT OF FRACTURES AND DISLOCATIONS OF CLAVICLE.

By E. BARTLETT, M.D.,

EXETER, N. H.

OF the various means by which efforts have been made to fulfil the indications for treatment of fractures and dislocations of the clavicle, the attention of your readers is invited to the "Ring and Sling" as now improved, and, it is believed, perfected since its inception over twenty years ago. Then it was announced as Dr. Bartlett's modified apparatus of Dr. Fox, and

was noticed by Prof. Hamilton in his work "On Fractures and Dislocations," though unfortunately the directions for its application referred to the *old* sling, while the woodcut represented the *new*.

The new sling is applied to the elbow only, and, by its guy-straps, buckled into the side-buckles of the ring, controls, most effectually, the desired position of the humerus, making it the medium through which the shoulder is carried upward, outward, and backward, without the interposition of an axillary fulcrum.

The ring is made in two hair-stuffed parts buckled together, and may be enlarged if required. It is applied to the shoulder of the sound side by sliding it up the arm, placing in the axilla that half to which the side-buckles are fastened, and having them look toward the median line. This position of the ring is important, and should be strictly observed. After placing the arm in front of the chest, so far as to have the hand rest easily in the strap at the ring, apply the sling to the elbow, and buckle the forward guy-strap to the ring, short enough to retain the arm in that position; then carry the other guy-strap across the back to the other side-buckle on the ring, drawing it sufficiently tight to reduce the fracture, which is indicated by the removal of the deformity.

This completes the indispensable dressing for *fracture* of the clavicle, but for greater security and firmness during the sleep of the patient, and especially in dislocations of the clavicle, the long strap should be applied by passing one end through the axilla of the

affected side, the other through the ring, and buckling them together across the scapula, as represented in the engraving.

For additional security to the elbow, a short strap is passed beneath the angles of the sling and buckled over the bend of the arm, loosely, so as not to stop the circulation.

In a case of dislocation of the scapular extremity of the clavicle it will be necessary, in order to keep the same in place, to put a sufficiently large and firm roll of bandage, as a compress, in the hollow above the middle of the clavicle, confining it by a strip of bandage fastened to the front and back guy straps of the sling, by pins, or needle and thread. This is better than the former method of placing the compress over the articulation and confining it by turns of a roller under the elbow.

Two cases of this dislocation have occurred in the practice of the writer, in both of which this treatment was successful. Three cases, one of dislocation of the sternal extremity, and two of the scapular end, were reported by Dr. Folts, of Boston, in which he used this apparatus with success. Of it he said: "I consider it the most perfect, for the treatment of all injuries the clavicle is liable to sustain, of anything with which I am acquainted."

In fracture of the neck of the scapula, and of its acromion process, it should be used with an axillary cushion; the elbow, in such case, not being brought forward and inward, but confined perpendicularly to the side by buckling the guy-straps of the sling accordingly.

There is, probably, no method which fulfils so many indications as this; doing it, too, with such precision, such ease and success, that a failure to treat all cases without deformity and disability should be regarded as malpractice.

The apparatus is manufactured by W. F. Ford, Surg. Dept., Caswell, Hazard & Co., New York.

### A NEW INSTRUMENT FOR THE ADMINISTRATION OF THE AIR-DOUCHE TO THE MIDDLE EAR.

By SAMUEL SEXTON, M.D.

NEW YORK.

THE appliance used by Dr. Politzer to connect his air-bag to the nose in administering the air-douche to a patient, consisted of a slightly curved hard rubber tube, which was inserted into the meatus to the distance of about one inch, when the patient's nose was seized with the thumb and forefinger and pressed until air-tight. This frequently caused wounding of the nasal passage, and was especially obnoxious to children. An improvement to this was made. Some American aural surgeon, whose name is unknown to me, suggested the use of a glass or hard rubber nose-piece, made oval in form, and partly entering the meatus, which answered the purpose very well. Its use, however, was attended with one difficulty, namely, it permitted the air to escape through the imperfectly closed nasal passages at times. Principally to remedy this last-named difficulty, Mr. Allen, of London, devised a "nasal pad," intended to be applied to both sides of the septum nares at the same time. With a view to further improve these appliances, I have had the Messrs. Tiemann & Co., 67 Chatham Street, construct a soft rubber instrument, which I have now used for several years, and find very useful. The accompanying cut renders a description

unnecessary. Being constructed of soft rubber, it can be applied to an infant without giving pain or alarm. It should be borne in mind, when using, that the in-

strument should be *pressed up against* the nasal openings, using care not to close the alae nasi by lateral pressure, as the object is to keep the passages *dilated* as the air passes in. It can be applied to all sizes and shapes of the nasal organ, and no air is lost in passing from the air-bag, to which it is attached, to the nasopharynx.

Its cleanliness is manifest, as it does not *enter* the nasal cavity, but is *pressed against* it, and having but one opening, which is large, it is easily cleaned.

### A NEW ATOMIZER.

By F. A. BURRALL, M.D.,

NEW YORK.

THE atomizer represented in the accompanying sketch

is exceedingly well adapted to the use of both practitioner and patient when a moderate amount of fluid is required. It consists of a rubber ball with valve attached to a glass atomizer of the form known as Newman's, which is modified by being connected with a small reservoir for holding the liquid. Atomizers have so many uses that a household is hardly complete without one. In coryza, dryness of the nares, sore-throat, and allied disorders, also for disinfection, these little instruments are very useful. They are also serviceable as aids to office treatment of nasal or throat diseases, since they can be used in the interval. An objection to metallic atomizers arises from their liability to become corroded, and although glass ones are more fragile, a little care will usually obviate this danger, and they are more easily cleaned.

I will not dwell upon the advantages of medicated spray in treatment, since they are generally admitted, but merely call the attention of physicians to this agent for vaporizing fluids. The instrument

is manufactured by Tiemann & Co.

ARMY NEWS.

*Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from August 12 to August 18, 1877.*

DICKSON, J. M., Captain and Asst. Surgeon. Relieved from duty in Dept. of the Gulf, and, on expiration of his present leave of absence, to report in person to the Comd'g General Division of the Atlantic for assignment. S. O. 172, A. G. O., Aug. 14, 1877.

BROWN, P. R., 1st Lieut. and Asst. Surgeon. To be relieved from duty with 5th Infy. upon arrival of A. A. Surgeon Redd, at Tongue River, and return to his station at Fort Shaw. S. O. 108, Dept. of Dakota, April 13, 1877.

Medical Items and News.

CONTAGIOUS DISEASES.—Comparative statement of cases of Contagious Disease reported to the Sanitary Bureau, Health Department, for the two weeks ending August 18, 1877.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-Spinal Meningitis.	Measles.	Diphtheria.	Small-pox.

Aug. 18 .....	1	25	42	2	13	17	0

THE LATE PROF. A. B. CROSBY.—At a meeting of the Faculty of the Bellevue Hospital Medical College, held Aug. 10, 1877, on motion it was unanimously

*Resolved*, That this Faculty humbly bow in submission, but with saddened hearts, to the Almighty, who in His inscrutable providence, has suddenly stricken down in the meridian of his career one of its most gifted and beloved members, ALPHETS B. CROSBY.

*Resolved*, That in this visitation it has lost one of its most cultured, lucid, impressive, and brilliant lecturers; one who, in imparting his valuable lessons, made study a pleasure by combining with his wealth of learning an aptitude of illustration, mingled with wit and humor, that crowded his class-room with enthusiastic and admiring scholars.

*Resolved*, That the members of the Faculty mourn the loss of one of their most accomplished and genial colleagues, one whose presence at their official and social reunions was always hailed with delight.

*Resolved*, That in his death we feel that Bellevue Hospital has been bereaved of one of its most skilled and faithful surgeons, the medical profession of one of its most eminent practitioners, the country of one of its noblest citizens, who, both in war and in peace, contributed his talents and energies with patriotic zeal in its behalf.

*Resolved*, That we offer our sincere sympathy to his wife and family in this trying ordeal; that while we are powerless to assuage their grief, we commend them to the sweet memories of his useful life, and to the tender mercies of Him in whom he trusted, who "has gone before."

ISAAC E. TAYLOR, M.D., *President*.

A. FLINT, JR., M.D., *Secretary*.

The following are the resolutions of the Medical Department of Dartmouth College:

*Whereas*, A sudden and afflictive dispensation of Providence has removed from us Dr. A. B. Crosby, of our Faculty of Instruction;

*Resolved*, That we desire to express our sincere sorrow, and our sense of personal loss, the loss of an instructor gifted, learned, and apt to teach, and of a friend and counsellor, genial, wise, and faithful.

*Resolved*, That we offer our heartfelt sympathy to the bereaved family and friends, with the earnest wish that in their memories of his noble life, in their confidence in his blessed immortality, in their faith in the God in whom he trusted, they may find comfort in this bitter hour.

WILLIAM T. SMITH,  
THOMAS AMORY DEBLOIS, } *Committee*.  
GEORGE F. ADAMS, }

HANOVER, N. H., Aug. 10, 1877.

CREMATION.—It is said that Dr. Winslow, whose body was recently cremated at Salt Lake City, Utah, resolved to adopt that method of disposing of his remains after viewing the partially decomposed body of his child during a visit to the family vault. He at least saved himself a similar mortification in the eyes of his friends.

CONTAGIOUSNESS OF SCARLET FEVER.—Dr. Longhurst (*Lancet*), in answer to some questions regarding the contagious character and communicability of scarlet fever, writes that the period in which the infection is most active is the stage of inflammatory fever up to the full development of the eruption; that the intensity subsides with the subsidence of the fever; and that it is not during the stage of desquamation. That the media of communication are the vaporious exhalations from the skin and the breath affecting the surrounding atmosphere and the clothes. That the patient may ordinarily safely rejoin the family circle at the end of the third week.

WHOOING COUGH.—English practitioners speak highly of the use of croton chloral in the treatment of whooping-cough. They claim that it has a marked tendency to shorten the duration of the disease. The dose for a child one year old is one grain every three or four hours.

THE BITE OF THE "COPPERHEAD" SNAKE.—Dr. Thos. A. Elder, of Millintown, Pa., reports (*Phila. Med. and Surg. Rep.*) the cure of a patient bitten by a "copperhead," in which case the gravest symptoms of systemic poisoning showed themselves. His treatment consisted in the hypodermic injection of fifteen minims of spirits ammonia aromat., diluted with an equal quantity of water, into the foot in the neighborhood of the bite, and the internal administration of half a teaspoonful to a teaspoonful of the aromatic spirits every hour until the urgent symptoms were passed. This was the fourth case of the kind similarly treated. In one six hypodermic injections were employed.

SECRET DRINKING.—A strong and determined effort is being made by the medical profession in England to break up the practice of the retailing of liquors by grocers.

CANAL BOATS, AIR CAPACITY OF.—A bill is before the English Parliament, providing that "three children and their parents may dwell in a boat where the gross cubic contents of the cabin are at least 200 feet, such children being of an age not exceeding six years."

HÔTEL DIEU.—The inauguration of the new Hôtel Dieu is to take place Sept. 1st.

**TREPHINING THE TYMPANUM.**—Dr. Bonnafont, of Paris, has trephined the tympanum with success for deafness, and ranks the operation in importance with that of removal of the cataract in eye-surgery.

**DR. FREDERIC S. DENNIS**, of this city, has passed the required examination of the Royal College of Surgeons of London.

**SUITS FOR FEES.**—The Fellows of the Royal College of Physicians of London never sue their patients for medical services. We presume that the reason is that it is undignified so to do.

**PUPERPERAL MORTALITY IN NEW YORK.**—The *Lancet* asserts that puerperal mortality in New York is nearly twice as great as in London.

**LEFT SIDE DEAFNESS** is said by Dr. Cassells, of Edinburgh, to be more frequent than deafness on right side, on account of the comparative smallness of the left nostril.

**FALLING OUT OF HAIR.**—Prof. Erasmus Wilson, in cases of defluvium capillorum, prescribes a lotion composed of strong liquor ammonia, almond oil, and chloroform, of each one part diluted with five parts of spirits of wine or spirits of rosemary, and made pleasant as to fragrance by the addition of a drachm of the essential oil of lemons. This should be dabbed upon the scalp after thorough friction with the hair-brush. No doubt there are cases in which this lotion must be used with caution, or largely diluted. In cases of alopecia he recommends frictions with a liniment composed of equal parts of the liniments of camphor, ammonia, chloroform, and aconite, to be well rubbed into the bare places daily.

**DIPHTHERIA.**—Lowell, Mass., lost 231 children from diphtheria in 1876, this having been the most fatal epidemic in its history.

**INVENTOR OF LARYNGOSCOPE.**—Señor Garcia was recently presented with a service of plate in recognition of his merits as the inventor of the laryngoscope.

**POPULATION OF SWEDEN.**—In 1800 the population of Sweden numbered 2,347,308 persons of both sexes; in the beginning of 1876, it had increased to 4,383,291. The population of Norway in 1800 was 883,038, and at the end of 1875 had increased to 1,817,237, an increase of 105.8 per cent.

**SALE vs. THE LOUISVILLE MEDICAL COLLEGE.**—Our readers who have noticed a report of this suit some months since will be interested in the following account, as published over Dr. E. S. Gaillard's signature in the *Richmond and Louisville Medical Journal*:

"In September last, Mr. Sale, a medical student and the plaintiff in this suit, entered the college mentioned. He paid his fees. A few weeks subsequently he was offered (with others) free tuition in a Louisville medical institution. This offer was a part of the sworn testimony of the plaintiff. He accepted it and requested a return of his money. This request was of course not granted. He then asked for his tickets. He was told that this college never gave its tickets (the evidence of attendance upon a course of lectures) until the last month of the course. Had the tickets been given there would have been no suit, but they were withheld, and the suit invited. The plea in this suit was failure to comply with promises made. In the garbled version of the magistrate's decision published in the *Courier-Journal*, and sent to the medical press everywhere, and to the alumni of the Louisville Medical College, it is admitted that this

plea could not be, and had not been, sustained by the evidence. The so-called 'judgment' of the magistrate was given on the ground that the present Faculty were not legally elected.

"The Book of Minutes of the Proceedings of the Board of Trustees shows that the members of the Faculty were not only legally elected by the present Board, but that one of the last acts of the old Board was to elect them (with one exception) before adjournment. It may be asked, why was not this book produced and such a 'judgment' prevented? The answer is simple: it was in possession of the persecuted Secretary of the Board of Trustees, Dr. B. M. Wible, who was ill and soon after died, and was found after his death, and after the so called 'judgment' had been rendered, and copies of it forced into a daily paper (which never publishes the petty business of a magistrate's court), and actively disseminated for purposes too evident to require indication."

**A MEDICAL CURIOSITY.**—In February of this year, Dr. Maske, of Görlitz, Germany, was called on to remove an iron nut from the penis of a peasant boy, who was nearly fourteen years of age. In the search after forbidden fruit, the boy had drawn the nut over his penis, but was unable to get it off. He had to walk a league and a half to the doctor's office, and on his arrival the penis was found to be in a semi-erected state, swollen, oedematous, and very red. The nut, which was about two-fifths of an inch in thickness, was situated about four-fifths of an inch from the pubes. As it was absolutely impossible to remove it by the way in which it was put on, a neighboring file-maker was called in, and after over an hour's work the upper part of the ring was filed through. It was then laid on a small anvil, the scrotum being carefully protected, and a blunted chisel was introduced into the opening made by the files, and by a few light strokes of a hammer the nut was sprung open to a slight extent. Dr. Maske then succeeded, by compressing the part of the penis which was situated behind the nut, in forcing it through the opening he had made. The penis soon regained its normal condition.

**VACCINATION PARTIES IN AMERICA.**—A Parisian contemporary soberly publishes an extract from *Le Télégraphe*, in which it is stated that it is at present the custom at soirées in Yankeeland, to offer the guests varied assortments of vaccine in lieu of cakes and other refreshments. "The domestics of other days are replaced by doctors, lancet in hand. Eight incisions are considered the correct thing, and both human and animal vaccine are used at the same time, some taking five points of animal vaccine and three of human, others four of each, and so on according to the fancy of the vaccinated. There are also soirées, at which the vaccinated meet to compare their arms and ascertain the success of the operation. It is not an uncommon thing for an American lady of the present day to express her preference for a certain gentleman in these terms: 'What would you have? We have been vaccinated together.'"

We have no doubt that this will prove news to most of our readers.

**THE CHARITY HOSPITAL IN BERLIN.**—During the last official year, 15,294 patients were treated, and 395 children were born in the Charity Hospital in Berlin. Of these patients 1649 died, 10,453 were discharged cured, 1255 were discharged improved, and 645 were discharged unimproved. Each patient cost on an average 55 cents per diem.

## Original Lectures.

## GRAVES'S DISEASE.

A CLINICAL LECTURE DELIVERED AT THE UNIVERSITY HOSPITAL,

By WM. PEPPER, M.D.,

PROFESSOR OF CLINICAL MEDICINE IN THE UNIVERSITY OF PENNSYLVANIA.

(Reported by Samuel M. Miller, M.D.)

FIVE cases of this interesting affection present themselves at the clinic to-day, and thus a good opportunity is afforded of illustrating many of its peculiarities. We give this name to a group of symptoms, of which enlargement of the thyroid gland, protrusion of the eyeballs, and disturbance of the heart's action are the chief. It is not merely the thyroid enlargement which constitutes the disease, for you know that in many parts of the world goitre, even of extreme degree, is very common, and yet such cases are not to be regarded as in any way identical with Graves's disease. It will be found, in simple goitre, that the enlargement is progressive, and consists of a simple hypertrophy of the gland, unattended with either pulsation or thrill, and that there is an absence of exophthalmos and of cardiac disturbance. Moreover, the causes which lead to simple goitre are often endemic, as in the valleys of Switzerland, although the affection also occurs in a sporadic form; but in such cases the peculiar influences which favor the development of Graves's disease are wanting. We can better appreciate these and other points upon a study of the present cases:

CASE I.—Mrs. J. L., 56, married, born in Germany. Has had twelve children, the youngest of them being at present 14 years old. Most of her labors have been difficult, particularly the last. She was much affected by the loss of her husband a few years ago, who died from the effect of gunshot wounds received during the war. She has suffered from frequent leucorrhœa, pain in her back, and other evidences of uterine disease. She has had rheumatism occasionally. Her menopause occurred two years ago, when she was fifty-four. Since that time she has noticed palpitation, choking sensations, blurred vision, and exophthalmos. She is of a very nervous temperament, and very easily frightened. She is dizzy every now and then. Blowing, anemic murmur in pulmonary artery. Pulse 140. No valvular murmur. Thyroid gland enlarged, with pulsation and slight thrill.

CASE II.—W. J., son of the above patient, *et.* 17; born in Philadelphia. Had several attacks of rheumatism last February. Marked prominence of eyeballs since middle of April. Pulse 108. No cardiac murmur. Occasional giddiness and dyspnoea. Thyroid gland enlarged, but this varies in degree at different times. No thyroid pulsation noticed. Patient has poor appetite, and is anemic.

CASE III.—Mrs. McN., Irish, *et.* 25. Had her only child four years ago. The labor was an easy one, and no complications ensued. Two weeks later her thyroid gland began to swell, and soon reached a very large size. She was also attacked with severe palpitation of the heart. There was also moderate protrusion of the eyeballs. After sixteen injections of ergotina at intervals of a week, the thyroid gland was returned to its usual size. The patient is very nervous, and the action of the heart, though controlled by digitalis, is easily disturbed, and becomes very rapid.

CASE IV.—Wm. S., *et.* 17, born in Bucks County, Pennsylvania. Had a severe attack of typhoid pneumonia at about the age of fourteen. Six months later he narrowly escaped drowning, and received a severe nervous shock. Last summer he had a mild sunstroke. After his escape from drowning he became very nervous and easily agitated. In six months palpitation of the heart appeared, and then marked enlargement of the thyroid gland. He has suffered frequently from sudden attacks of giddiness, or of marked flushing of the face. There is still decided enlargement of the thyroid, with thrill and pulsation. Heart's action much disturbed, but no valvular murmur; slight exophthalmos.

CASE V.—John M., *et.* 15, born in Philadelphia. A badly developed boy, with a rachitic chest. Palpitation of the heart appeared six years ago, without apparent cause; a year later the thyroid gland began to swell. No exophthalmos. The thyroid is now enormously swollen, the right lobe being a little larger than the left. There is a strong thrill felt over the gland. There is no organic disease of the heart. Pulse varies from 86 to 110, with, at times, spells of palpitation and dyspnoea. Occasionally he experienced difficulty in swallowing.

Graves's disease most frequently occurs in persons of a decidedly pronounced nervous temperament, and hence it is by far most common in females. It is met with, however, in both sexes, and, as the above cases show, at almost any period of life. I have seen a typical case in a man of over sixty years of age. Though certainly very rare in boys, I am able to-day to show you three such cases. There have only been two others during the past eight years at the University clinic. The causes which produce this disease are excessive care, anxiety, overwork, particularly if combined with deficient or improper food. In some cases, as in Case IV., it would certainly seem that the disease was induced by pregnancy or confinement, and in not a few cases, in females, the predisposing cause seems to be severe uterine disease or menstrual disorders. I have spoken of the three principal symptoms, but a glance at the cases will show that these symptoms are present in different degrees in different cases. For instance, the enlargement of the thyroid gland may be moderate or even slight; or, on the other hand, it may be truly enormous. In these latter cases there may be occasional sensations of strangling or of great difficulty in swallowing, from the pressure of the enlarged gland upon the trachea or œsophagus. It usually happens that the enlargement varies from time to time. As a rule, both lobes are equally affected, though one may be somewhat larger than the other. The thyroid gland is highly vascular, and the arteries leading to it are very tortuous. When, then, there is violent arterial over-action we would be prepared to find pulsation and thrill over the gland. These phenomena are frequently present in Graves's disease; in some cases they are present at times only, while in other cases they may be absent throughout. The characters of the thyroid enlargement point strongly to the view that it is due to a dilated and enlarged condition of the vessels with some hypertrophy of the glandular and fibrous tissue, and possibly with a varying degree of interstitial serous effusion. In connection with this we must note that there is frequently violent throbbing of the carotids and of their branches.

The exophthalmos is no less varying in its intensity; in some cases it is so slight as to attract but little attention; while in others it is so extreme that the globes cannot be covered by the lids, and it becomes necessary to protect them from injury by exposure to air

and dust. The protrusion seems to be due to the distention of the vessels of the post-ocular tissues, with serous infiltration, and perhaps some hypertrophy of the celluloso-fatty tissues behind the globe.

The disturbance of the heart is the most constant, and is frequently the earliest of the symptoms. It also varies much in degree. There is rarely any organic disease at first, though after excessive palpitation has long existed, excessive hypertrophy may supervene. The action of the heart is rapid—90 to 130 per minute—and is also liable to paroxysms of irregular palpitation, sometimes from very slight causes. Owing to the anæmia which usually coexists, it is not unusual to find marked anæmic murmurs at the base of the heart, along the course of the pulmonary artery, and over the jugular veins in the neck.

In considering the three symptoms above mentioned, and in looking for a common cause which might explain their development, it cannot fail to suggest itself that such a cause would be found in a morbid condition, with enfeebled activity of the cervical ganglia of the sympathetic and of the cardiac plexus of nerves. In consequence of this, irregular overaction of the heart and dilatation of the vessels of the neck and head would result—conditions which we have seen to be present in Graves's disease. This, then, may be regarded as the probable pathology of this affection. In a few cases actual lesions of the nervous ganglia have been found; but I do not think it at all necessary that any serious demonstrable structural changes should exist, at least not in the early stages. A state of great depression of their functional activity would explain all the symptoms, and the frequency with which complete cure results would seem to indicate that this is often the only condition present.

We have seen that there are frequently associated instances which are of precisely the character to develop such a morbid state of the vaso-motor nerves. Anæmia, nervous shock, or exhaustion—systemic exhaustion from severe attacks of illness or from pregnancy—may be again mentioned. So, too, there are a few special symptoms occasionally present which are all readily explainable in the same manner. Among these may be mentioned sudden flushing of the face, with violent throbbing of vessels and sensations of fulness or vertigo; local sweatings about the head, which sometimes are unilateral; local modifications in nutrition, such as irregularities in the growth of hair.

The diagnosis of Graves's disease can present but little difficulty if attention be paid to the characteristic features above indicated. It is really a very curable affection in many instances, provided it come under treatment at an early stage, and the hygienic conditions can be rendered favorable. Even when cure cannot be effected, the troublesome symptoms can be held in check. In advanced cases, or when the cause persists, the symptoms grow more grave. Anæmia becomes intense, dilatation of the heart, with degeneration of its muscular fibre, ensues, circulation fails, dropsy supervenes, and death follows from exhaustion and general anasarca.

In the treatment the greatest care must be given to the removal of the causes, and in securing rest, good food, change of scene, and entire release from cares. The various functions must be carefully attended to, and any local disorder in females removed by suitable treatment.

The remedies upon which I rely with most confidence are digitalis, iron, ergot, and bromide of potassium. These are required to meet the different indi-

cations, and will, therefore, be called for in different proportions in different cases. Digitalis is the most valuable remedy for controlling the functional disturbance of the heart. It may be given freely (gtt. x. to xv., three or four times a day), and continued for long periods at a time. Iron is absolutely essential when anæmia exists, as is so frequently the case; and when this condition is marked large doses of iron should be administered, in whatever form is most acceptable to the system. Ergot has proved of much value in my experience. Not only is it given internally, with a view of influencing the contractility of the walls of the arteries, but we have obtained most excellent results from the injection of diluted ergotina into the substance of the enlarged thyroid glands. The needle may be introduced to the depth of half an inch or an inch, and from six to ten minims of a solution containing ninety-six grains of ergotina to the fl. ℥ i. of distilled water injected. In Case III. it will be seen that after sixteen such injections, repeated at intervals of about a week, complete reduction of the enlarged gland was effected. In other cases we have obtained equally favorable results. Bromide of potassium is frequently called for, partly on account of the general nervous condition, but chiefly to assist the digitalis or ergot in controlling the irregular action of the heart and arteries. We may employ such of these remedies as seem specially indicated in any given case, varying the combination or mode of administration according to the progress of the symptoms. In order to secure success, however, persistent and careful hygienic and medicinal measures will be necessary.

### FRACTURE OF THE BONES OF THE FACE,

WITH INJURY TO THE EYE AND OBLITERATION OF THE NASAL DUCT.

By CHARLES S. BULL, M.D.,

SURGEON TO THE NEW YORK EYE INFIRMARY AND TO CHARITY HOSPITAL.

FRACTURES of the upper jaw are by no means so common as those of the lower jaw, but the results are much more serious. Direct blows on the bone are the most frequent cause, and there is almost always some displacement. Still, a blow in the face from before backward, may cause a transverse fracture of the superior maxilla below the malar bone, which is prolonged to the pterygoid apophyses, fracturing them on a level with the bottom of the pterygo-maxillary fossa, without any displacement. Violent blow below the orbits fracture not only the maxillary bones, but also the vertical plate of the palate bone and the pterygoid process of the sphenoid, and yet with very little resulting displacement. Furthermore when the nasal process of the superior maxillary bone is broken, and the nasal bones driven in, emphysema of the subcutaneous tissue of the face is produced and as another complication, permanent obstruction of the nasal duct. Another point to be remembered is, that injury to the infraorbital nerve and its branch is frequent, which may cause entire loss of sensibility over the parts supplied by this nerve, or in rare cases a hyperæsthesia of the nerve and its branches.

Since the nasal ducts lie so deeply hidden within bony walls, slight external injuries to the facial bone can produce but little effect upon them. But occu-

ionally we meet with cases of violent injury, where the effect has been a driving or crushing in of the nasal or superior maxillary bones, or both, and these severe injuries may involve the calibre of the nasal duct. One cause for a stricture resulting in such cases is a naturally narrow base to the nose, where the nasal processes of the superior maxillary bones are pressed inwards and thus diminish the transverse diameter of the duct. Moreover, it is well known that fractures of the nasal bones, by thus narrowing the sac and duct, may give rise to dacryocystitis and thus to stricture. An obliteration may result from contact between two lacerated surfaces after some such injury.

The following three cases illustrate very clearly the results of severe injury to the facial bones, in a more or less complete obliteration of the nasal duct:

CASE I.—Farmer, *et. 45*; first seen April 21, 1875. Two years before, he had received a violent kick upon the left side of the face and temple from a vicious horse, which threw him to some distance, and rendered him unconscious for several hours. There was great laceration of the face, profuse hemorrhage, and long-continued suppuration. Pieces of bone came away at varying intervals for nearly eighteen months after the accident. The sight of the left eye was lost completely, and ever since the overflow of tears and pus from the eye has been constant. When I first saw him the deformity was very marked. The nasal bone had been driven outward and backward, and was partly absorbed by necrosis, the orbital plate and nasal process of superior maxillary fractured, the external angle of frontal bone comminuted, the nasal bones driven downward and crushed in, and the whole orbit displaced downwards and inwards, so that the inferior orbital margin was three-fourths of an inch lower than the opposite side. The eye was atrophied, sightless, the result of rupture and subsequent iridophoroiditis, and was turned outwards and almost immovable. There was some ectropium of the lower lid, and pus could be squeezed out from the lachrymal sac through the lower punctum. The direction of the blow had evidently been from above downwards and outwards. There was a marked depression on the side of the nose, covered by a broad cicatrix, through which the man said the pieces of bone had made their appearance. The bridge of the nose did not exist, but in its place was a depression, showing how the nasal bones had been crushed in and flattened. The left nostril was closed and would not admit of the passage of the smallest-sized Eustachian catheter. After some difficulty I succeeded in passing a small guttug bougie through the nostril into the pharynx. The lower canaliculus was then slit up, and an attempt made to pass a Stilling's knife into the nasal duct, but it was immediately arrested at the junction of the sac with the duct, and no amount of force could cause it to advance. I then tried small silver probes, but with no better success. The duct was completely obstructed by what seemed an unyielding bony wall, and the immediate effect of the injury had, no doubt, been increased by the subsequent necrosis of the bone or bones, and the subsequent further sinking in of the bony walls. All attempts to re-establish the duct were abandoned. The stump of the eye was enucleated and the lachrymal sac was destroyed by cauterizing with nitric acid. This was done from the interior by the method practised by Dr. Agnew. The upper canaliculus was slit up, the whole anterior or external wall of the sac divided, the lips of the incision held apart by retractors, and the cavity of the sac carefully washed out with water. Then a small cotton swab,

soaked in nitric acid, was carefully applied to the inner surface throughout its whole extent; the retractors were withdrawn and cold applications made. The slough came away on the fourth day, and the subsequent contraction and closure of the cavity went on rapidly. The contraction of the cicatrix, together with the natural sinking-in of the lids after enucleation, also caused a disappearance of the slight ectropion of the lower lid.

CASE II.—Laborer, *et. 40*; first seen in August, 1875. Two years before, while helping to pile up a number of barrels of lime, one of the barrels rolled off the pile, fell about five feet and struck him directly on the face, knocking him down. He lost a great deal of blood, and when taken to the hospital, both nasal bones and the left superior maxillary bone were found fractured. The nasal bones and the nasal process of the maxillary were crushed in, and the latter comminuted. He was in the hospital eighteen weeks, during which time numerous small pieces of bone came away, and the necrosis had evidently involved a considerable portion of the upper jaw. The lower part of the wound remained open for some time after his discharge from the hospital, and one or two small pieces of bone came away through an opening just below the internal tarsal ligament of the left side. This opening then closed, but ever since then there has been a purulent discharge from the left lachrymal sac and some from the conjunctiva. When I saw him he presented the following appearance: The bridge of the nose flattened and very much broader; nasal bones driven in, so as to leave the nasal cartilage projecting at a sharp angle; a deep hollow on left side of nose, where the nasal process of the superior maxillary is met with, showing a considerable loss of substance from necrosis; marked narrowing of the left lower meatus of the nose, owing to the left lateral wall of the nose having been driven in by the blow, or having sunken from the process of necrosis. Pus could be pressed out from the lachrymal sac through the canaliculi. Chronic conjunctivitis, with a tendency to the development of pannus on upper part of cornea. The original blow had evidently been directed from the right side towards the left, and from above downwards, for although the right nasal bone had been fractured, the violence had not extended to the right superior maxillary bone, nor was there any interference on this side with the nasal duct.

On the left side, however, there was evidently a permanent obstruction, if not obliteration, of the nasal duct. The canaliculi were both slit up, and a Weber's knife passed into the lachrymal sac. It was arrested at the junction of the sac with the duct, and could not be passed any farther. A Stilling's knife was then used, but with the same result—the resistance was a hard, unyielding wall. There was evidently an obliteration of the calibre of the duct by a sinking in of its bony walls. An attempt was then made to pass a probe upwards into the duct from its inferior opening in the nose, but this could not be found, owing to the above-mentioned narrowing of the nasal fossa.

There remained, therefore, only one thing to be done, destruction of the lachrymal sac; and this was effected in the same way as was described in the previous case. The slough came away on the sixth day, and then the cavity gradually closed, granulations springing up from the bottom.

CASE III.—Stricture of the nasal duct and fistula of the lachrymal sac, with partial facial paralysis following injury.

Laborer, *et. 31*; first seen in February, 1877. About two months previously, while excavating a subcellar,

a mass of earth fell from above upon him, completely covering him. He was immediately dug out, but remained unconscious for some time. His face was badly cut, and the hemorrhage was profuse. An examination showed a depressed fracture of both nasal bones, and of the nasal process of both superior maxillary bones, with considerable displacement of the fragments, particularly from above downwards and from the right towards the left. There was also partial facial paralysis of the right side with ptosis, and paralysis of the superior and external recti muscles of the right eye. When I first saw him the facial wounds had all healed, the cicatrices were contracting, there had been no necrosis of the bones, but the ptosis, facial palsy, and paralysis of the ocular muscles remained. There was an opacity of the right cornea from keratitis, with  $V = \frac{2}{3}$ . The orbit was displaced downwards, about three-quarters of an inch lower than the other side, the lower lachrymal punctum was obliterated, and there was a fistulous opening into the right lachrymal sac just below the lower margin of the internal palpebral ligament, through which a probe passed into the sac, and pus was discharged. There was a cicatrix running from the side of the nose, through the lower lid just internal to the puncture, and involving the conjunctiva, showing where the lid had been lacerated and the canaliculus and punctum closed. Though the lower margin of the orbit was so far displaced, yet there was no break in its continuity perceptible under the finger, nor was there any sign of callus round a fracture to be felt.

The lower and upper canaliculi were opened with scissors, and then a Weber's knife introduced. This was arrested at the commencement of the nasal duct, and could not be passed any farther. A Stilling's knife with a sharp point was then introduced, and firm, steady pressure made from above downwards. The obstruction slowly yielded a little, which was somewhat encouraging, and the knife was then withdrawn, turned round 45°, and again introduced by firm pressure. This manœuvre was repeated until four incisions had been made, but still the end of the duct had not yet been reached. A Bowman's probe, No. 7, was then introduced, pushed down as far as possible, and retained in place by a band of adhesive plaster round the forehead for about ten hours. It was withdrawn and cold applications made until the next day. The knife was again introduced and an attempt made to extend the incision, but it was found that contraction had taken place since the removal of the probe, and that the work had to be done over again.

It was then decided to give up any attempt at reconstructing the nasal duct, which was as completely obliterated by the results of cicatricial contraction as if its bony walls had fallen in and come together. The only thing left was destruction of the lachrymal sac and obliteration of its cavity, and this was done by the same means employed in the two previous cases, though in a somewhat different manner. The external fistulous opening was enlarged, and the tissues freely incised down to the sac, and its entire anterior wall laid open. The nitric acid was then applied as before and the wound kept open and carefully cleansed. The slough came away on the seventh day, and then the cavity began to close, though the process went on somewhat slowly. At the end of about nine weeks the only sign left was a somewhat irregular cicatrix, which produced a small amount of ectropium of the inner end of the lower lid, but as there was not much overflow of tears, this was not interfered with.

47 EAST TWENTY-THIRD ST., N. Y.

## ON THE EFFECT OF STIMULATION ON AN EXCISED NERVE.

By WILLIAM LEE, M.D.

BALTIMORE, M.D.

BERNSTEIN\* has shown that taking, as we seem to be justified in doing, the negative variation seen on the galvanometer as an outward sign of the internal disturbance in a nerve-fibre which constitutes a nervous impulse, we may draw certain conclusions as to the nature of the latter—more especially that it is a wave of molecular disturbance which passes along the nerve; and he succeeded in estimating the wave length, form, and the rate of transmission. He does not make any statement as to the nature of the molecular movement concerned, but says it cannot be very different from those of electricity, magnetism, or heat,† and he does not seem to imagine that it could be a movement associated with or dependent on a wave of increased chemical metamorphosis passing along the nerve-fibre. If, however, the process were mere vibration, we have no reason to suppose that the passage of an impulse would exhaust the fibre. The molecules set swing by an impulse would, when it ceased, return to their position of equilibrium, and the fibre be in exactly the same condition as before; while, were the process one of chemical combination (it could not be one in which chemical separation preponderated, for that would necessitate a continual independent source of energy to carry it on), the passage of each impulse would use up some of the combining material, and so a nerve-fibre, removed from sources of supply and stimulated, ought to cease to be irritable sooner than a similar fibre not stimulated.

If, then, of two nerves removed from the body and treated as similarly as possible, except that one was stimulated more frequently than the other, no constant difference in the duration of irritability after removed was found to exist, we would be justified in concluding that the process was merely one of vibration, with a restoration of the *status quo* when disturbing force ceased; but if the stimulated nerve died sooner than the other, we would have to conclude that a process of chemical change (the using up of some alterable matter) was associated with the passage of the impulse. The experimental investigation of this question was suggested to me by Prof. Martini and was carried on under his direction in the Biological Laboratory of the Johns Hopkins University. The method of my experiment was as follows:

The sciatic nerves were removed rapidly, but with great care, from an animal, and placed at once in moist chamber. This chamber contained two pairs of apolarisable electrodes (DuBois-Reymond's), and two pairs of platinum wires, each pair fixed in the bottom of a groove in a piece of paraffin. The distal end of each nerve was laid on one of a pair of apolarisable electrodes—the middle point lay on the clay of the other—and its central end over one pair of the platinum wires. The conducting wires from each pair of the DuBois electrodes passed to a Thomson reflecting galvanometer, keys being intercalated in their course, by which the natural nerve-current from either pair of electrodes could at pleasure be sent through the multiplier or broken out of it. Each pair of platinum wires were connected with the secondary coil of a DuBois induction apparatus, having magnetic interruption, through the primary coil

\* Untersuchungen über den Erregungsvorgang im Nerven- und Muskelsysteme. Von J. Bernstein. Heidelberg, 1871.

† L. c., page 36.

which was sent the current derived from two Leclanche cells arranged abreast. The position of the secondary coil in the experiments varied from 4 s.m. to 6 s.m. on the scale. By means of keys, the interrupted current from the secondary coil could, at will, be sent through either nerve or cut off from both. This complicated arrangement was necessary, as I had to use the cessation of the appearance of the negative variation on stimulation as a sign of the death of the nerve, the ordinary employment of contraction of the muscle, connected with it as a sign of the nerve's vitality, being unavailable on account of the complication which might be introduced by muscular fatigue or exhaustion. The electrodes were carefully prepared before each experiment, and tested with strings moistened with 0.75 per cent. salt solution laid over each pair of platinum wires, to see that they produced no deflection of the spot of light on the galvanometer's scale, either when the interrupted current was passing through the platinum wires, or when it did not.

The nerves having been laid over the electrodes as above stated, the progress of the experiment was as follows:

The natural current of each nerve was thrown into the galvanometer and measured, and then the interrupted current passed through the corresponding platinum wires, and the corresponding negative variation noted. If, as sometimes happened, no distinct negative variation was observed, a fresh pair of nerves was prepared, and the experiment commenced anew. A suitable pair of nerves having been obtained, one was frequently tetanized, the other only rarely, and just long enough to allow its negative variation to be observed, and the time at which each ceased to give a negative variation noted. As, on account of the shifting of keys necessary to connect the nerves alternately with the galvanometer, the exact moment of death of each nerve could not always be found, the nearest five minutes to the time of the discovery of death was taken in each case as the time of death. In the earlier experiments the interrupted current was sent through the worked nerve for five seconds at a time, with ten seconds' rest before the next tetanization. Next I employed ten seconds' stimulation, alternating with five seconds' rest; and finally, after varying still more the time, I continuously sent through a weak stimulation, with, in each case, such brief interruptions as were necessary from time to time for testing the other nerve. The earlier experiments were performed on the sciatic nerves of the terrapin; the latter, those of the frog. In alternate experiments the first and the second nerve removed from the body was the one chosen for stimulation. The result was that in no case did the worked nerve live so long as the resting; the greatest difference being 50 minutes, and the least 20 minutes; the average difference was 35 minutes. The exactness of the difference of time, and its invariable relation to the stimulation, seemed to preclude the supposition that it was due to accidental causes; but to be certain of this I made four experiments with nerves removed and placed as above, but left at rest, except for the short similar stimulation applied at intervals of five minutes to each, to ascertain if it still gave a negative variation. In no one of these experiments did the time of persistence of functional activity after removal from the body, in the nerves of each pair differ more than 5 minutes. In one case, taking the above rule of assuming the nearest five minutes to the time of death, both nerves died simultaneously; the actual difference observed was two minutes. Detailed account of the experiments is given in a tabular form below.

As a result we may, I think, conclude that the nervous impulse is not simply a wave of movement of simple physical character passing along the molecules of a nerve-fibre whether that be part of it (which is perhaps possible) or no; there is something more. When the impulse has passed the fibre does not return to its previous state, it is permanently altered (if removed from the circulation), in a way that makes it less capable of further activity, and it consequently ceases to respond to stimuli sooner than it otherwise would do. It seems reasonable to suppose that this change is due to the using up of some material in the fibre as the impulse passes along it—that, in fact, the wave of molecular movement, which accompanies, or rather is the impulse, is not simply a rhythmic swing from position of equilibrium and back to it again, such as, for example, air experiences when a sound wave passes through it, but is a molecular movement associated with chemical changes—in fact, is a wave of increased chemical metamorphosis.

According to Pflüger's well-known avalanche theory, the greater effect produced on a muscle, when its nerve is stimulated at a distance, than when the same stimulus is applied close to the muscle, is due to the fact that nervous impulse increases as it travels along the nerve-fibre. This, of course, implies a using-up of some source of energy as the impulse travels (*i.e.*, a conversion of potential energy stored in the fibre into kinetic). The disturbance in one section does not simply pass on into the next unaltered, but rather acts on it as a liberating force arousing the dormant activity of energy, yielding material in the next section; the process would be like that occurring in a gradually increasing train of gunpowder ignited at its smaller end. There are several objections to this "avalanche theory" as an explanation of the phenomenon in question, but one object which I had in view in undertaking the above experiments was in reference to it. If, namely, the result had been that the stimulated nerve died no sooner than the resting, this theory, which necessitates during the passage of an impulse a using-up of material (of which the nerve removed from the circulation could only have a limited store), must be completely disproved. As will be seen, the actual result obtained does not affect it one way or the other.

TABLE I.—STIMULATED AND RESTING NERVES.

No. of Expt.	Animal whose nerves were used.	Duration of vitality of excited-stimulated nerve.	Duration of vitality of excited-resting nerve.	Difference.	Character of stimulus.
1	Terrapin.	80 min.	110 min.	30 min.	Tetanized 5 sec. Rest 10 sec.

## Reports of Hospitals.

### BELLEVUE HOSPITAL.

#### NOTES OF PRACTICE AND PECULIARITIES OF TREATMENT.

##### EMPHYEMA FOLLOWING PNEUMONIA—EARLY ASPIRATION—RECOVERY.

THE woman was admitted to the hospital in June, 1875, and had a certain amount of pus removed from the right pleural cavity. She left the hospital before recovery was complete, got married, and upon her return for examination exhibited a fine-looking boy about one year old. As far as her countenance indicated she was in perfect health.

The history of this case during her stay in the hospital in 1875 was as follows:

She was 22 years of age, temperate, and gave no evidence of specific disease. Her mother died of cancer; otherwise her family history was good. One morning in June, 1875, she was seized with a chill which lasted for several hours, followed by fever and pain beneath the right breast of a severe lancinating character, which continued throughout the night of the same day and up to the time of her admission to the hospital on the 22d of June—two days after she was attacked. On admission, her face was flushed, the pain in the side intense, the temperature 105° F. She was placed in bed, and a full dose of quinine administered. She had the physical signs of pneumonia at that time, such as dulness upon percussion, increased vocal fremitus, bronchial breathing, etc.

She passed through the pneumonia. On the 7th of July there was evidence of fluid in the right pleural cavity, and on the 20th of July a hypodermic needle was introduced and pus obtained. On the 23d of July, an aspirator needle was introduced and  $\xi$  xvi. of pus removed. The expectoration was profuse and muco-purulent, but there were no evidences of pneumo-hydrothorax. On the 28th of July, the patient's friends, not wishing to have her "stuck with the needle," removed her from the hospital. At her examination, May, 1877, she stated that, after her removal from the hospital, she expectorated large quantities of purulent material, but did not have her chest aspirated. In May, 1877, there was found good resonance and good respiration over the entire right side of the chest. The woman had not noticed at any time that one side of the chest was smaller than the other. The case, then, was interesting as evidence of the value of early aspiration with the view of preventing retraction of the chest walls. What became of the pus which remained in the chest after the aspiration, and that which formed subsequently, was a question. It was

thought probable that perforation of the lung took place and that the pus was removed by expectoration.

#### DIABETES MELLITUS—CHRONIC BRIGHT'S DISEASE—IMPORTANT CLINICAL QUESTION.

There were several points of interest in the case, which gave the following history:

A female patient, aged 48, a large and apparently stout, healthy woman, complained of having had cough and expectoration for many years, of having raised blood occasionally, and of having had rheumatism several times. (?) She had never noticed any change either in the quantity or color of the urine until about one week before admission into the hospital, when she began to pass more frequently than usual and in larger quantities; at the same time she had marked increase of thirst as compared with that present before admission. About a week previous to her admission she also noticed that her right foot and leg were swollen, and she had some vomiting, but no headache. At the time of examination she complained of pain in the joints and lower extremities. On physical examination the thoracic and abdominal organs were found normal.

The urine was acid, pale in color, had a specific gravity of 1040, contained albumen and large hyaline casts. Farther examination showed that the urine contained sugar, and the quantity passed daily was  $\xi$  xxviii. Her appetite was poor and thirst considerable. She had received no injury upon the head, nor were there any cerebral symptoms.

The *first* point of interest in the case was the co-existence of Bright's disease and diabetes mellitus. The two affections are occasionally found associated in the same person. In some instances, it was believed, it is fair to impute the kidney disease to the persistent diuretic action of the sugar in the blood. Yet the two diseases are not found very frequently associated.

It has been thought that there is a certain amount of conservatism as regards the renal disease in the diabetes; the presence of sugar in the urine acting as a diuretic, operates as a protection against the accumulation of urea in the system.

The *second* point of interest related to the duration of the two diseases. It seemed from the patient's account that the disturbance from which she suffers has extended back only one week before admission to the hospital. If that be true, and there was no diabetes prior to that date, it cannot be said that the diabetes produced the renal disease, for probably the renal disease had existed much longer, as there was no evidence that it was acute Bright's disease.

Assuming that the diabetes was of only a week's duration, it was stated in that connection that sugar occasionally appeared temporarily in the urine. The quantity is not large, sometimes only a mere trace; but the fact that a simple trace of sugar is occasionally found in the urine of healthy persons was regarded as an important fact, and one to be borne in mind, in order to avoid being led astray by the fact.

The *third* point of interest related to the quantity of urine secreted. The quantity was considerably reduced from the normal, the woman passing only  $\xi$  xxviii. in twenty-four hours, and it had a high specific gravity (1040).

Was it because the kidneys were damaged, the secretory power diminished, and hence the presence of sugar did not excite diuresis? The question remained unanswered. With regard to *treatment*, it was proposed to do but very little. It was believed not to be judicious to place the patient upon anti-diabetic remedies, for the diabetes might prove to be

only temporary. The expectant plan was recommended until some positive indications for treatment were developed.

**COLICA PICTONUM—NOTABLE EVIDENCE OF LEAD AFTER THE ADMINISTRATION OF A BATH CONTAINING SULPHATE OF POTASSIUM.**

A male patient, a worker in lead, had been sick about three days. He was attacked with pain in the abdomen, in the region of the umbilicus; there was no vomiting, not much tenderness upon pressure, and no rigidity of the abdominal muscles. The absence of rigidity of the abdominal muscles was regarded as sufficient to exclude peritonitis, no matter how localized it might be. The pain had been continuous, day and night, and he had also had more or less pain in the chest and other parts of the body. The blue line was well marked. A bath containing sulphuret of potassium was given, and the man's hands became nearly black; his body also had very much the same color. His pain had been relieved by opium, and his bowels had been moved by jalap and injections of assafetida. The visiting physician remarked that he had come to regard *croton oil and belladonna* as almost a specific for lead colic. One week after, the man was convalescent.

**JAUNDICE TOLERATED FOR A LONG TIME WITHOUT GIVING RISE TO UNFAVORABLE SYMPTOMS.**

A male patient, at 51 years, was jaundiced, and the skin had a sufficiently dark color to indicate that the jaundice had existed for some time. With the exception of pneumonia about twelve years ago, and "malaria fever" about eight years ago, continuing for two years, he had always been a healthy man. He had been in the habit of going on an "occasional spree," but knew of no cause for the jaundice which was present. It came on gradually, and had been present for *two years*. Notwithstanding the jaundice, his appetite and general health had remained good. The interesting point in the case was the tolerance of the coloring matter of the bile to such an extent and for so long a time without giving rise to grave symptoms. If the obstruction to the exit of bile is not absolute, such a jaundice may be developed and continue for a long period of time without doing special harm, except to the appearance of the patient.

**SIGNS BY WHICH PHTHISIS IS RECOGNIZED IN ITS EARLIEST STAGES WITHOUT THE AID OF PHYSICAL EXAMINATION OF THE CHEST.**

1. Retraction of the skin over the cheeks.
2. Cerulean hue of the sclerotic, due to anæmia of the conjunctiva.
3. In bronchitis and emphysema there is conjunctiva, and also in the later stages of phthisis.
4. Atrophy of the lips, of the ears, and a thin pinched appearance of the nose. Whenever the skin closely covers cartilages, as in the ears and nose, a showing through, as it were, of the cartilaginous framework is one of the earliest signs of loss of flesh.
5. Pallor of the cheeks and face as compared with each other and with the malar surfaces.
6. Dilatation of the nostril upon the affected side. This is the case in all pulmonary affections, but especially in the early stages of phthisis.
7. The respiration is invariably accelerated, and the disturbance affects expiration as well as inspiration. In certain nervous disturbances the respiration is accelerated, but it is the inspiration only which is at fault.
8. Sinking of the clavicle more upon the affected

side than upon the opposite, and giving the appearance of having a very long neck.

8. Great hyperæmia of the pillar of the fauces, present long before the pulmonary disease manifests itself, and continuing until pus is expectorated. When purulent expectoration is established, decomposed pus irritates the throat, and then the other parts usually become hyperæmic.

9. Intense congestion of the throat, early hoarseness, and vomiting are unfavorable symptoms, and indicate enlargement of the bronchial glands. This vomiting is caused by pressure upon the pneumogastric by the enlarged glands. A large proportion of phthisis cases will tell of having had sore-throat for a number of years previous to the development of any chest symptoms.

**TREATMENT OF THE SORE-THROAT WHICH MAY LEAD TO THE DEVELOPMENT OF PHTHISIS.**

The local application of a saturated solution of nitrate of silver in glycerine once in ten days was recommended. The theory was that an acute inflammation had a natural tendency to get well, whereas a chronic inflammation had no such tendency. The object was to substitute an acute for a chronic inflammation, and the inflammation caused by nitrate of silver recovered much quicker than that caused by most of the other caustics. Then use a spray or gargle of common salt-water three or four times a day. Occasionally an antiseptic should be added, and the best was said to be oil of cinnamon, wintergreen, pepper, etc. These oils all contain carbolic acid. Twenty drops of the oil of cinnamon added to a carbolic acid solution destroys the smell and rather increases its efficacy—certainly does not detract from it.

It was maintained by the visiting physician that enlargement of the bronchial glands was secondary to irritation in the throat; hence the possibility of such sore throats becoming the starting-point of tuberculous development in the lungs must always be taken into consideration. It was also said that, in a majority of cases in which enlargement of the bronchial glands was found at post-mortem, it would also be found that the patient had suffered from catarrh of the nose when alive.

## Progress of Medical Science.

**RESEARCHES ON THE TEMPERATURE OF SARCOMA.**—In six cases of sarcoma, more or less pure, but all growing rapidly, Prof. J. A. Estlander, of Helsingfors, measured the temperature and compared the results with the temperature, measured with the same precautions, of the corresponding parts of the other side of the body. He constantly found an elevation of the temperature of the sarcoma of from 0.8 to 1.5 degrees of Celsius. This elevation is not due to any inflammation of the integument over the tumors, for in none of the six cases was the skin the seat of this morbid condition, and in one case the cutaneous covering no longer existed, the tumor being naked. Neither does the richness of the tumors in arterial blood account for the increased warmth, for the former, in some cases, surpassed that of the arterial blood in a normal condition. The author thinks that a great part of the phenomenon which he has observed is to be attributed to the morbid processes themselves, occurring with so much activity in the diseased tissues. This hypothesis also explains the fever which is often observed in patients afflicted with rapidly growing sarcomas. It

is naturally much easier to recognize an increase of temperature over a large sarcoma than over a small one; but in case No. 6, where the tumor was not larger than a split hen's egg, and the skin over it was completely movable and free, the temperature was more than a degree higher than over the corresponding part of the other side. The augmentation of the temperature is probably in direct proportion to the rapidity of growth of tumors in general, and the author is himself opposed to the conclusion that a warm tumor is necessarily from this fact alone a sarcoma. "As a general rule, one may only say that a hot tumor grows rapidly, and, according to all probability, is a sarcoma."—*Nordiskt Medicinskt Arkiv*, Bd. 9, 1st Häft.

**FECUNDATION OF THE HEN'S EGG IN THE OVIDUCTS.**—Dr. P. Tauber (*Naturh. Tidskr.*, R. 3, Bd. 10) divides this subject into two queries:

1. How long a time can a hen continue to lay fecundated eggs after separation from the cock, and how many fecundated eggs can such an isolated hen lay?

In the historical remarks with which the author introduces this section he refers to the assertions of Fabricius ab Aquapendente that one fecundation suffices for the remainder of the year, and Coste's doctrine that one fecundation is only effective for 5-7 eggs, which are laid in from 10-14, at the most 18 days after the hen's isolation—only dark yellow eggs of 15-35 millimetres diameter being capable of fecundation.

The author's investigations yielded the result that one treading suffices to fecundate 5-7, rarely 8 eggs, and that it was generally effective only till the 11th, rarely till the 18th day.

2d. Is there in the hen's oviduct any particular place which can be rightly designated as a seminal receptacle?

The author here gives a general view of the hen's oviduct, in which, among other things, he denies the presence of glands. With regard to his especial subject, he divides it into the "tube" and the "infundibulum." He directs especial attention to the structure of the last-named portion, especially to a zone near the border of the infundibulum, which contains numerous excavations; these are, in his opinion, the special seminal receptacles. He finds that it generally takes the semen from 14 to 24 hours after the treading to arrive at this zone.

In contradistinction to Coste's idea that the fecundation occurs in the ovary, his investigations show that this probably occurs in the infundibulum, and that it is highly improbable that it can take place in the ovary. Especial attention is directed to the fact that on the rupture of the follicle in the infundibulum the semen comes into direct contact with the germinal membrane.—*Nordiskt Med. Arkiv*, Bd. 9, Häft 1.

**SYPHILITIC FATHERS AND HEALTHY CHILDREN.**—Dr. Güntz, of Dresden, reports six cases in which the fathers of healthy children were the subjects of latent syphilis. In each of these cases at least two years had elapsed between the latest manifestations of syphilis and marriage. In several cases, the first child was syphilitic, the second healthy. In all of the cases, within a few years after the birth of their children, the deeper syphilitic lesions manifested themselves in the persons of the fathers, all of whom had had good reasons, among others the birth of healthy children, to suppose that the disease was eliminated from their system.—*Vjhrschr. f. Dermatol. u. Syph.*, and *Phila. Med. Times*, July 7, 1877.

**SUCCESSFUL REMOVAL OF A LARGE FIBROID UTERUS WITH BOTH OVARIES.**—Mr. Knowsley Thornton relates a case in which recovery took place after removal by gastrotomy of a large fibroid uterus with outgrowths, and both ovaries. The patient was 38 years old, married, but had never been pregnant. The tumor had been first noticed nearly three years before. The operation was performed on January 10th. In opening the peritoneum a coil of intestine was wounded by the point of the knife, but the wound was at once closed by a continuous suture of fine silk. The pelvic portion of the tumor could not be dislodged, until the mass of the tumor was drawn out of the incision and used as a lever, by being pressed over the left iliac crest. This mass was then transfixed and ligated with two strong strings, and it was then cut off. Room was thus gained to get at the broad ligaments, which were transfixed and tied with double ligatures. The ovaries were then cut away. Finally the cervix was transfixed and tied, and the mass above it cut away. All the ligatures were cut short, and the abdomen was closed. The operation occupied rather more than an hour and a half. The ice-water cap was used on two occasions in the after-treatment, the temperature having risen to about 101°. On the ninth day some red, offensive serum came away per vaginam, and this discharge continued till the eighteenth day. It then ceased, and at the same time pain was complained of in the right iliac region, and the pulse rose to 124. On examination by speculum a small slough was found plugging up the external os, and on pulling it away a quantity of fetid pus escaped. Convalescence then progressed favorably, and on the thirty-seventh day the patient was able to go out.

Mr. Thornton believes that this is the first successful case of removal of the uterus and ovaries, in which all the pedicles were tied with silk and left free in the peritoneum. He prefers this to the extra-peritoneal method, thinking that it is attended by less danger of septicæmia or of hemorrhage, experience having shown that the danger of hemorrhage when the clamp or wire separates is by no means small.—*Obstetrical Journal*, June, 1877.

**CASE OF CROUP CURED BY SWABBING OUT THE LARYNX.**—Dr. Durodié, of Bordeaux, recently had under treatment a case of croup in a child seven years of age, in which tracheotomy became indicated. The parents, however, refused to sanction the operation, and the Doctor, as a last resort, determined to swab out the larynx according to the plan first recommended by Dr. Green, of New York. The child was securely held, and the left index-finger of the operator was introduced into its pharynx as far as the opening of the larynx; a small sponge, which was firmly secured at the end of a piece of curved whalebone, was then dipped into warm water, and, guided by the finger, was pushed into the larynx, where it was rapidly moved up and down three or four times before being withdrawn. This manœuvre was repeated three times at each visit, and each time the sponge, when withdrawn, was covered with the débris of false membranes. This treatment was continued four days, when all danger of asphyxia disappeared. When the treatment was begun, the patient was in the last extremity, and the improvement was manifest at once. Dr. Durodié thinks that the success was due in part to the reflex spasmodic movements provoked by the contact of the sponge with the laryngeal mucosa, these movements causing the ejection of the portions of the false membrane left by the sponge.—*Gazette des Hôpitaux*, June 19th.

# THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

## MEDICAL CERTIFICATES IN THE DAILY PAPERS.

THE number of letters which we receive from medical men in this city and elsewhere, regarding the publication of medical certificates in the daily papers, proves to us that there is a strong feeling against the practice. It is easy to see why this is the case. In fact, were it not that certain parties persist in allowing their names to be used in the daily papers, in connection with a certain widely advertised mineral water, it would seem hardly necessary to argue the question. We may be, perhaps, too radical concerning medical advertising; but, if this be so, it is the result of a firm conviction that every species of it is absolutely wrong. Even if there was no Code regulating our relations to each other, there would be no excuse for such manifest unfairness as a privileged advertisement of one individual or set of individuals, to the exclusion of the others, equally if not more meritorious. We put it mildly when we say it is undignified to resort to such devices, but we have a right to mean a great deal more. If the rule was to publish every little operation in the daily papers, every little discussion in a medical society, and the like, there would be no occasion to do more in the interests of progressive medicine than stimulate the laggards to incessant zeal that they might make the best of their opportunities. As the opposite, however, is the case, we have some hope that the continued protests may be respected. Our confidence in the honor, dignity, and good sense of the profession is such that we cannot imagine it will tolerate, even on the part of its best men, such flagrant violations of the Code as those to which we refer. We believe the time has come to treat the whole matter fearlessly and above board. The exalted position of the individual magnifies his culpability. If this be not so, then the Code of Ethics has been framed merely for the bene-

fit of the older men, who, while pretending to follow its letter, openly violate its spirit. The rank and file of the profession look to them for an example; but when the trumpets of the watchmen give an uncertain sound, upon whom must our faith rest?

In view of the strong feeling against individual advertisements in any and every form, it becomes every one who really has a desire to be just to his brethren and honorable to his profession, to avoid any appearance of evil, and thus not only abstain from giving offence, but be always ready with a good example.

The opinion of a professional man, as such, is only valuable on a professional subject. With medical men these opinions are respected in accordance with the relative standing of the individual who delivers them, and may or may not do good. This is legitimate enough as far as it goes, inasmuch as, in a discriminative audience of his peers, few if any can be misled. With the general public this is so different that medical certificates of any and all sorts, for the secular papers, are conventionally forbidden. The risk of evil consequences to the profession, in allowing any medical man who may choose to do so to advertise in such a covert manner, is hardly counterbalanced by any good which the public may obtain from the most extensive use of the best mineral waters in the world.

The line should be drawn somewhere, and why not at the top of the page? This is a question which so directly bears upon the duties of the comitia minora of our County Society that it seems almost like impertinence on our part to call attention to it.

Aside from the tendency to degrade medical opinion to the level of cheap and meaningless certificate writing, there is a tendency to prostitute it still further by ministering to the tendency for self-prescribing among the people, and lowering the public estimation in the efficacy of drugs generally. It does not require a distinguished medical man to prove that any particular mineral water is agreeable to the taste, and hence a beverage; that it is effervescent because it contains carbonic acid, and hence possibly useful to dyspeptics; but when they deliberately recommend an article which they are willing to classify as a medicine, to indiscriminate use with the public, it can hardly be considered a professional proceeding. If this be allowed as a precedent, we may next hear some of our distinguished physicians recommending to the public some new European novelty in the shape of a "corn salve," "pile ointment," or "hair dye." We are inclined to sympathize with the gentlemen in question for the unpleasant notoriety which they have gained in this matter, and ask for them a suspension of judgment until they shall have the time and opportunity to explain their positions, and possibly withdraw their names. Probably the gentlemen are out of town, do not see the papers, and are consequently not account-

able. In any event, let us hope for the best, and believe for charity's sake that these certificates were obtained by accident, and that the names are used without authority. At the most, however, the public will not suffer, as any who may be interested in trying the new medicine will know where to go, in case of difficulty, for first-class medical advice. With less distinguished men the case might be different.

#### THE HOMŒOPATHIC QUESTION.

In our present issue we publish a letter referring to the other side of the homœopathic question. This is but a sample of many others which we have received upon the subject, and so well illustrates the popular sentiment that we present it on that account to our readers. Although each writer says he is not warranted in speaking for himself, he still says substantially the same thing, and presents the general idea of the present correspondent. So far, then, we cannot blame the homœopaths for the lack of interest in the matter, or want of desire to be liberal on all questions affecting their peculiar doctrine.

### Reviews and Notices of Books.

**SYMPATHETIC NEURO-RETINITIS.** By ADOLPH ALT, M. D. 8vo, 11 pp. New York, 1877. (Reprint from Report of Fifth International Ophthalmological Congress.)

**ANATOMICAL CAUSES AND THE NATURE OF SYMPATHETIC OPHTHALMIA.** By ADOLPH ALT, M. D. 8vo, 88 pp. New York, 1877. (Reprint from Archives of Ophthalmology and Otology.)

1. THE author admits that cases of sympathetic neuro-retinitis are very rarely mentioned, but thinks this is the result of a failure to diagnose the disease. It may also be claimed, perhaps, that he has himself made an incomplete diagnosis in some of the seven cases presented. In four of the cases the eye first affected was lost by a disease without an injury.

2. This article is based on the personal examination of thirty-two eyes, and the records of the examination of seventy-eight by others. The statistical results of these investigations are arranged in tabular form. Table first gives the condition of each of the tissues of the enucleated eyes. The other nine tables give details of the eyes lost by affections of the several tissues. The study of this brochure will prove highly useful to the specialist, and it may be regarded as a valuable contribution to the literature of the pathology of the eye.

**METHOD OF PERFORMING POST-MORTEM EXAMINATIONS.** With special reference to medico-legal practice. [From the *Charité-Annalen.*] By PROFESSOR RUDOLPH VIRCHOW. Philadelphia: Lindsay & Blackiston. 1877.

THIS monograph contains an introductory portion, which is followed by the post-mortem records of three cases. In the introduction a description is given of a systematic and scientific method of performing autopsies, with the reasons for pursuing a definite order in every detail of the examination. The records of the three cases were made in accordance with the principles laid down in the introduction, and beautifully

illustrates how thorough, complete, and satisfactory examinations in medico-legal cases can be made. The established reputation of the author is a sufficient guaranty for the excellence of the book.

**ALCOHOL AS A FOOD AND MEDICINE.** A Paper from the Transactions of the International Medical Congress. By EZRA M. HUNT, A. M., M. D., President of the Section of the Am. Med. Association on State Medicine and Public Hygiene, Vice-President of the American Public Health Association, etc., etc. New York: Scribner, Armstrong & Co., 743 Broadway. 1877.

THE "conclusions" reached in this paper were "quite unanimously" adopted by the Section of the International Medical Congress before which it was read, and were ordered by the General Congress to be transmitted as a reply to a memorial sent to said Congress by the National Temperance Society. The memorial asked the Congress to declare that alcohol is not a food in any sense to the human system; that its improper use is productive of a large amount of physical disease, etc.; that when prescribed it should be done with conscientious caution, and a grave sense of responsibility; and that it should recommend total abstinence from alcoholic beverages.

The memorialists, probably, would not have received a more satisfactory answer, had a special committee been appointed by the Congress, than by accepting and turning over the paper presented by Dr. Hunt. The Doctor writes with ability and vigor, and we came near to saying with an incisiveness which comes only from a predetermined effort to drive King Alcohol out of the field entirely. His paper is a prime article for distribution by the prohibitionists, contains a goodly number of common sense sayings, and in argument is ingeniously arranged. The subject has been studied under three questions: 1. What is the value of alcohol as a food? 2. What is its value as a medicine? 3. How far is it modified by the variable composition of spirituous liquors, or by the unreliability in manufacture?

In answering the first question the author starts with the proposition that any article to rank as food must be convertible into tissue or force, in such a way as to contribute to healthy vitality and aid the body in the performance of its normal functions. The milk analysis is then taken as the most reliable key to the study of the other foods. On this basis it is argued that alcohol must be excluded from the nitrogenous foods; that it has no place among the heat and force-evolving foods; that it does not possess any power to produce an accumulation; that the statement cannot be accepted that because alcohol does not escape from the body it must be oxidized in the body, and therefore must partake of the nature of a food; that it cannot receive recognition as an accessory or auxiliary food; that it does not arrest metamorphoses of tissue and thus secondarily result in nutrition; that it does not act catalytically; and that, if a food, it is not a necessary food. Thus we have a most thorough eradication of alcohol from the dietary list.

The second question is answered in the same cleansing manner, and the author has routed alcohol from the list of medicines because it does not help to heal or repair that which occurs in consequence of disease. It is admitted, however, that it may possibly be classed among general stimulants, and that its use is permissible "if no other article is at hand, and may be never so good as a medicine in such emergencies" as sudden failure of the heart's action. Here we have a halting recommendation, followed by an admission that alcohol may prove itself a valuable medicine under cer-

tain circumstances. What more does the reasonable physician claim for any article which he places among his resources in treating emergencies? The expression "if no other article is at hand" seems like a conscientious interpolation, because, shortly afterwards, the warning is found that "even then it should not be relied upon alone, for there are attendant evils," and of those, embarrassment to the ready passage of the "agglutinated cells" to the extreme capillaries and disturbance of the rhythmical relations existing between the water, carbon, oxygen, etc., in the blood-globules, are enumerated. Now, this may be purely scientific—doubtless is; but there are, in medicine, many beautifully-spun theories which count but little at the bedside of the sick. It is probably the experience of a vast majority of successful practitioners of medicine that, in the treatment of numerous cases, alcohol plays a useful and important part, notwithstanding science has failed to recognize its "*modus operandi*," which is embarrassingly obscure." But it is to such loose clinical experience that the author objects. He has a right to do so, but the objection does not disturb the existence of the fact.

In answering the third question, or statement, the impurity of the alcoholics is brought forward to modify their applicability. If the profession was compelled to use every known alcoholic fluid, the argument might have some weight; but as it stands, it is of equal value in nullifying the "clinical experience" derived from the use of almost all other remedies, the same as that derived from the use of alcohol. Very many of our most successful practitioners, however, now employ only alcohol, not alcoholic preparations, and by so doing can regulate the dose with all the precision that any known preparation of medicine can be regulated. There is, therefore, no reason why clinical experience derived from the use of alcohol may not be as reliable as that derived from the use of any other remedy of known strength. But alcohol has not been used, generally, when alcoholic stimulants have been employed in the treatment of disease; hence, its effect has not been correctly estimated. Granted; but that fact cannot be used as an argument against the efficacy of alcohol as a remedial agent.

What the author says relative to social and moral questions, and the relation which the physician sustains to them, is worthy of a hearty approval. The conclusions at which the author arrives, however, are tame indeed, when compared with the argument by which they have been reached. They make one feel as though, having grasped the bull by the horns, the doctor cannot knock him down for fear of injuring his feelings.

THE ANCESTORS OF PRESIDENT MACMAHON.—President MacMahon comes from a medical family. His great uncle was the physician of Franklin, the friend of Voltaire, and a pronounced atheist. His grandfather received the degree of Doctor at Rheims in 1739, and in 1742 went to Autun. While there he became the physician and friend of three aged noblemen, married one of their relatives, and soon after received from them a gift of 2,500,000 francs. The deed of gift was sworn to before a notary named Changarnier. Many years afterwards the grandson of the Doctor, Marshal MacMahon, and the grandson of the notary, General Changarnier, were companions in arms in Africa. The heirs of the noblemen brought suit to recover the money given to Doctor MacMahon, on the ground of undue influence, but the suit was decided against them.

## Correspondence.

### THE HOMŒOPATHIC QUESTION.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—Noticing your remarks on homœopathy in the July 28th issue of your journal, and being pleased with your evident desire to treat the subject in a liberal and scientific spirit, I thought you might not object to the publication of a few remarks from the other side, especially if made in the same spirit. While I make no pretensions to any authority to speak for any one but myself, I am nevertheless well aware that very many of us (perhaps a majority) have such a desire for the prevalence of truth, and the advancement of medical science in all its departments, that we would hail with delight all new facts, whether they accorded with any previous ideas or theories we may have held, or not. I do not think it necessary that I should maintain that medicines which cure when given in accordance with the homœopathic formula, *similia similibus curantur*, effect that desirable end in a well known and definite manner. The question should be as to the fact of such result, not losing sight at the same time of the other fact, that this may or may not have been reached in the way we supposed; but if not, what matters that? While I administer medicines upon this method (whatever its real nature may be) in the great majority of my practice, I do not hesitate to admit that I often find cases where a rigid adherence to homœopathic doctrines would not, in my opinion, give the greatest relief to my patients. I might regard this as evidence of the incompleteness of my knowledge of this system, did I not know this departure in certain cases to be so general among practitioners of our school. I do not believe this law of cure to be an absolute and unvarying law of nature, because I have witnessed too many of its failures; and yet I could not be induced to deprive my patients of the benefits of it, and believe with you that "nothing in a progressive science can be exclusive."

If we claim that, and attempt to enforce it, the result must be that of complete inertia of medical science.

What is needed is more of the spirit of toleration among medical men, and the cultivation of such a spirit of impartiality as will prevent the rejection of anything on account of its source. Why, for instance, should Dr. Dessau after reading an article upon the action of small doses of certain medicines, consider it necessary to apologize to his learned colleagues, and disclaim any leaning towards homœopathic doctrines? He, or any one, has an undoubted right to use them in that way; but who did so first? And who in justice should have the credit of the good or evil resulting from their use in this way? Why should he deem it necessary to invent an explanation of their action, other than the homœopathic one, before venturing before a body of the so-called regular profession? Nothing but the existence of prejudice on their part, and the absence of that spirit of liberality and fairness, so necessary among scientific men, could make such measures and bush-beating excuses necessary. I know we have just such illiberal men in our own ranks; and I know also that many men of the old school are truly liberal individually, while in their societies they permit the illiberal majority to apply the regular lash, and hold them in the traces. Would it not be infinitely better and more in accordance

with the spirit of the age, if medical men would look to the medical education and attainments of those who wish to fraternize with them, and to their peculiar views upon minor questions afterwards? Why should a great medical school like the University of Pennsylvania refuse to accept a student from another than their recognized regular medical schools (see its advertisement in the *MEDICAL RECORD*), providing said student has as great a knowledge, when presenting himself, as if he had taken one or two courses with them? Is not the possession of a certain amount of knowledge of more importance than the place where it was obtained? Would it not be extremely silly for scientific men outside of medicine to break up into schools holding different views of this or that question, and refuse to have anything to do with each other because of this difference of opinion? One thing we all have need to complain of, and that is the low standard of medical education in this country. That a medical man can be educated thoroughly in all the branches he ought to understand, in two or even three years, is, we all know, an utter impossibility. Once this standard becomes sufficiently elevated in all medical schools, and physicians more imbued with the scientific spirit of the age—out of which alone progress can come, and which asks only for the facts, agreeable or disagreeable to their preconceived opinions, in order to adopt and hold until the next forward step is taken—may we not expect less intolerance and a greater desire to learn, no matter from whom that information may be derived. For my own part, I consider myself a physician, although, as a matter of fact, I am also what is known as a homoeopathic physician, though I care but little for the latter designation. I am in direct fellowship and association with the latter body, because there alone I find that freedom of opinion which will enable me to believe what I please: and to arise in a medical society and recite the treatment of a case, either with infinitesimal or crude doses of medicines, without being abused and hooted from the platform. Until such freedom can be granted me in the old school ranks, I prefer to remain where I am, because I shall never surrender my independence while I live.

In conclusion, allow me to express the hope that the day is not far distant when all medical men will be found willing to work together for the common good of humanity, whether all believe alike in all things, or not. In this wish I believe you will cheerfully join me.

Yours truly,

S. J. BUMSTEAD, M.D.

DECATUR, ILL., August 11, 1877.

## APPLICATIONS TO EUSTACHIAN TUBE

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—I do not remember having seen mention made of the method I have used, for some time past, to reach the Eustachian tube with medicinal applications, and so forward it to you.

In common with many of the brethren, I was at first delighted with the nasal douche, but the deleterious effect of stimulating irrigation upon the auditory apparatus has long since caused its discontinuance by me, except in very rare cases. A method which I have found to answer every good purpose of the douche consists in the *gentle* snuffing into the nostrils, one at a time, of warm water, either simple or medicated, and its forcible expulsion by blowing. After having been thus cleared of adherent mucus, the nostril of the affected side may be filled with the medicinal solution, closed with the finger, and the head thrown

back and towards the affected side. The solution will be immediately felt about the faucial opening of the Eustachian tube, and, if in sufficient quantity, will much more effectually bathe the entire post-palatal region than is possible by gargling.

As far as my observation goes, there is no possible danger in the use of this method, provided the remedy be very *gently* taken into the nostrils, and the solution employed be weak—depending rather upon its *frequent* use than upon its strength.

GEO. L. ANDREW, M.D.

LAPORTE, IND., August 13, 1877.

## RHEUMATISM.—ITS TREATMENT BY SALICINE, SALICYLIC ACID, AND SALICYLATE OF SODIUM.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—In visiting the different hospitals since I have been in Europe, I have taken great pains to ascertain the results that have been obtained in the treatment of the above disease with the remedies before mentioned.

Like most other questions connected with the therapeutics of our profession, I find a great diversity of opinion expressed by those with whom I have conversed.

The two extremes I found in Prof. Sanders, of the University of Edinburgh, and Dr. Jacob, house physician to the Leeds Infirmary. The former gentleman assured me that, after trying salicylic acid to his entire satisfaction, he had become convinced that it was worse than useless in the treatment of rheumatic affections, on account of its tendency to derange digestion and lower the vitality of the patient, without eradicating the disease for which it was given. He treats the disease now entirely expectantly, shielding the parts affected from the air by carded wool, over which is applied a layer of oiled silk, and giving anodynes to relieve pain when urgently demanded.

Dr. Jacob, on the other hand, considers these remedies almost in the light of specifics for rheumatism; and gave me access to his carefully tabulated record of treatment in seventy-seven cases, a part of which he has already published. In forty-five of these cases the benefit was so marked that the value of the remedy was beyond a doubt. In these forty-five cases the average duration of the disease was only three days, the shortest being one day, and the longest seven days.

But these cases were not the only ones that were benefited by the treatment, for of the whole seventy-seven there were only five cases in which the remedy was an entire failure. Three cases out of the five cases proved fatal, two from the accession of typhoid symptoms, and one by the supervention of a cerebral complication.

The two classes of cases least benefited by the drug were those of moderate severity and those in which there existed an extreme condition of hyperpyrexia.

In the last mentioned class of cases the cold bath seemed to be the best remedy, and eventuated in a cure, except in the case of brain complication.

Cardiac symptoms supervened in only two of the seventy-seven cases, after the treatment was begun. The plan pursued was to allow the patients to remain in the wards, well covered up in bed, for from one to three days before any active treatment was tried. This was done in order to see whether the case was one of well-marked rheumatic disease, or only one of an abortive type. After this period had elapsed, if the patient had not gotten decidedly better by his rest and confinement in bed, he was put upon salicylate of sodium

or salicine in thirty-grain doses, or the salicylic acid in twenty-grain doses every four hours, until the temperature was brought down to the natural standard and all the other symptoms ameliorated.

After this result had been obtained, the remedy was given three times a day for a week or ten days, to prevent a relapse.

Of these allied remedies the salicylate of sodium and salicine were preferred, on account of their less liability to disturb the stomach.

It is also believed, from the experiments, that salicylate of sodium exercises the greatest control over the disease.

If symptoms akin to quinism should manifest themselves during the treatment, the dose of the remedy given should be lessened, but not discontinued.

Dr. Jacob believes that the reason why others do not get so favorable results in their trials with these drugs, is that they are not given in sufficiently large doses.

In looking over the charts, I found the influence of the remedy given upon the temperature was most marked.

In forty of the cases it was reduced within twenty-four hours to the natural standard, and never rose again in but very few of them.

W. S. CALDWELL, M.D.

(of Warren, Ill.)

LONDON, August 1, 1877.

### INGROWING TOE-NAIL.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—In MEDICAL RECORD No. 351, under "Medical Items and News," reference is made to a method of treating ingrowing toe-nails, recommended by Dr. C. G. Clarke in the *Medical and Surgical Reporter* for July 7, 1877, which consists simply in scraping with the point of a knife a longitudinal line along the middle of the whole nail to transparent thinness, supplemented, at your instance, by a piece of cotton under the nail.

We will not find, perhaps, in all minor surgery a more seemingly insignificant affection than an ingrowing toe-nail; yet I am confident few are more deserving of careful consideration, as the conscientious testimony of scores who have experienced its extreme painfulness can truly verify. Medical men, moreover, seem to regard its tender management as something unbecoming their professional dignity, and in the vast majority of instances send their patients away with the very valuable advice: "Scrape a longitudinal line in the centre of the nail to transparent thinness, . . . and insert a piece of cotton under the nail;" or, what would accomplish the same in way of a cure when the case is well advanced, *paint the soles of the feet with tincture of iodine, and point them to the north pole*. This method, so favorably spoken of by Dr. Clarke, is one of the least palliative of all palliative measures; for, regarding the nail as an appendage of the skin, and essentially an epithelial structure, the degree of irritation brought about by the process of scraping would eventuate in proliferation of the epithelial elements, great thickening, and a condition of the nail resembling a cicatrix through its substance. Following this, firm and very pronounced adhesion of the nail to the subjacent matrix will be observed, with almost complete immobility of the nail, thus effectually destroying the prime factor of the palliation. It is important to recognize the comparative mobility of a healthy nail upon its matrix, and watch with care and caution to steer clear of any process that would cause this fixation to be more firm, if any good is expected

from palliation. To study the morbid anatomy of this affection, let us take, for instance, a perfectly healthy nail, free from contortion or other anomaly, and apply the cause universally produced of ingrowing toe-nail, and note the progress of the changes thus instituted.

From the combined lateral and downward pressure the nail is made to sink deeply into the flesh, causing irritation, determination of blood to the part, and active congestion. The same exemplification of the law is found here as in other parts of the organism, viz.: that repeated or prolonged congestion leads to hypertrophy and hyperplasia of the cellular elements, with marked redundancy of the soft tissues. This condition being attained, we find the nail imbedded in a great mass of flesh. The pressure being gradual, it soon makes for itself a groove of condensed epithelial and cellular tissue. The pressure from without remaining the same, irritation will increase with the growth of tissue, until finally the nail is made to cut through this hardened groove, and is now found in actual contact with parts rich in blood-vessels and nerves. Continuing the irritation and causal factor, the redundancy of soft tissue increases, granulations spring up around the edge of the imbedded nail, accompanied with great heat, redness, pain, swelling, and a discharge of irritating ichorous and sanious pus. This brings us to the last and worst stage of ingrowing toe-nail, with its accompanying intense pain and unrest. Can any good now result from *scraping a longitudinal line in the centre of the nail*, or by *inserting cotton under its angle*? Is it not apparent that such treatment would be *inane* than useless? Is there, then, any radical cure for this nail aside from evulsion or any cutting operation? I will answer that there is a method of treating this nail that is quite as satisfactory as evulsion, far less painful, and above all, is an eminently conservative process. In the first place, drop a few drops of *Liquor Potassa* (℥ iij. to ℥ i), as recommended by Dr. Sidney Ringer) upon this ulcerated surface with its imbedded nail, four or five times a day, and you will soon notice a diminution of the discharge, a cutting down of the granulations, and the edge of the nail beginning to pulpify. Here I am met with the objection that this will give rise to intolerable suffering. The pain, acute at first, will soon pass away, and leave the patient much more comfortable than before. Practising this for a short time, a partly flexible condition will be observed in the inverted nail, which renders it, with proper care and caution, easily elevated, without causing the patient a deal of pain. When this is done, take a thin piece of selected cork, which, being smooth, flexible, and capable of accommodating itself to this bed of granulations, is gently inserted under the nail, to be followed by almost instantaneous relief. Compressed sponge, lint, and cotton wool are all open to a common objection, viz., their properties of absorbing the discharge from the granulations and retaining it in contact with the sore, which is highly detrimental to its favorable course and cure. They are, moreover, too heating, and not sufficiently firm and elastic to exercise the necessary degree and kind of pressure. These latter indications are fulfilled most admirably and perfectly by the cork, causing, by constant pressure, atrophy and wasting of the granulations and the great mass of redundant tissue. Aside from these properties of the cork, by constantly elevating the nail, it separates to an appreciable extent the nail from its matrix, thus causing, in the course of a few months, a marked narrowing of the nail.

Having suffered for a number of years with this an-

noying and very painful affection, and believing that a radical cure has been effected by the above method of treatment, I respectfully suggest it to those of your readers who are suffering from the same, as a substitute for evulsion, and much superior to any method of palliation.

I am, sir, with much respect,  
Yours, etc., J. D. NEET.

VERMILLES, KY., AUGUST 6, 1877.

## MAGOTS IN A NEWLY-BORN INFANT.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—The following seems worthy of record, if for nothing else than its curiosity:

On the 17th inst. I attended Mrs. P., primipara, in confinement at No. — West Twenty-sixth street, near Tenth avenue. Saw her and the child daily until the 21st, during which time nothing of moment occurred to either. The child was well washed daily, and apparently well cared for. Calling again on the 23d, I found the child with its right lower eyelid greatly swollen, and a number of angry-looking swellings on various parts of the face; all of which, the mother assured me, had developed within twenty-four hours. Examining the eyelid more closely, I observed an opening through the skin near the external angle of the eye, looking as if punched out. Firm pressure exerted from this orifice a magot about one-quarter of an inch in length. Directing my attention to the other swellings, I found *seven* more; viz., two from one opening in the upper lip, two from one place beneath the jaw on the right side, one on the left, one from the right ear, and one from the palmar surface of the left thumb, all alive and *squirring*. Next day, the 24th, the openings were nearly all healed.

Though *magots* are not unfrequently bred in neglected wounds in hot weather, I know of no recorded instance in which a newly-born infant, with a healthy skin, has been *fly-blown*.

LAURENCE JOHNSON, M.D.

323 WEST TWENTY-SEVENTH STREET, July 26, 1877.

## New Instruments.

### AN IMPROVED TROCAR AND CANULA.

DR. JACOB A. WOOD, of this city, has devised a very useful modification of the ordinary trocar-canula which will commend itself to every one who has met with the usual difficulties and annoyances attending the

CASWELL, HAZARD & Co.

operation for tapping. The liability to the sudden arrest of the flow through the canula is well known, as

CASWELL, HAZARD & Co.

is also the great difficulty, oftentimes impossibility, of re-establishing it until the patient is placed in bed,

when the mattress and bed-clothing become more or less saturated with the oozing.

Dr. Wood, appreciating the cause of the difficulty to be a closure of the inserted end of the canula by omentum, or intestine drawn thither by the discharging fluid, conceived the idea of pushing away the obstruction and at the same time make the tube pervious. To secure these ends he slides into the canula a catheter, the closed extremity of which is perforated by numerous small holes. Dr. W. informs us that the instrument was made as early as 1855, and is only now brought to the notice of the profession not from any idea of its extraordinary merit, but simply at the request of several medical gentlemen who by accident became acquainted with its value and efficiency.

## ARMY NEWS.

*Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from August 19 to August 25, 1877.*

ALDEN, C. H., Major and Surgeon. On account of illness, relieved from duty as Chief Surgeon of reserve column of troops of the Nez Perces Indian Expedition, S. O. 113, Dept. of the Columbia, Aug. 11, 1877.

STERNBERG, G. M., Major and Surgeon. To take charge of the sick and wounded at Camp Bancroft, I. T., proceed with them to Grangeville, I. T., and there establish a field hospital. S. F. O. 28, Hdqrs. Dept. of the Columbia in the field, July 14, 1877.

KIMBALL, J. P., Captain and Asst. Surgeon. Relieved from duty at Fort Brady, Mich., to proceed to New York City, and report in person at these Hdqrs. for assignment. S. O. 190, Div. of the Atlantic, Aug. 22, 1877.

DICKSON, J. M., Captain and Asst. Surgeon. Assigned to duty with U. S. Troops at Indianapolis, Ind. S. O. 190, C. S., Div. of the Atlantic.

HALL, WM. R., 1st Lieut. and Asst. Surgeon. Assigned to duty as Medical Officer with the cavalry commanded by Captain Perry, 1st Cavalry. S. F. O. 28, C. S., Dept. of the Columbia.

SALICYLIC ACID AND SALICYLATE OF SODA IN THE TREATMENT OF NEURALGIA.—Dr. Descroizilles has employed salicylic acid and salicylate of soda in seven cases of neuralgia, with satisfactory results. The number of cases is too small to permit a judgment to be formed from them of the therapeutic value of the two drugs, but they demonstrate the advantages which the salt possesses over the acid in the treatment of this disease. All the cases were cured, but in the three cases in which the acid was administered it produced a certain amount of deafness. In two of these cases it also exerted an energetic irritant action on the mucous membranes of the digestive and respiratory tracts, and in the other it caused vertigo, general weakness, and well-marked hebetude. The salt did not exert any injurious action either on the mucous membranes or on the nervous system. It was not necessary to give it in as large doses as the acid, and the cure was rapidly effected. From one to five grammes of the salt were given daily, while in one of the cases treated by the acid, as much as seven grammes were given in one day. In all the cases the treatment was begun with small doses (1-2 grammes), which were increased by a gramme a day until the desired effect was obtained.—*Le Progrès Medical*, July 21st.

## Medical Items and News.

**CONTAGIOUS DISEASES.**—Comparative statement of cases of Contagious Disease reported to the Sanitary Bureau, Health Department, for the two weeks ending August 25, 1877.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-Spinal Meningitis.	Measles.	Diphtheria.	Small-pox.
Aug. 18 .....	1	25	42	2	13	17	0
Aug. 25 .....	0	14	44	3	10	29	0

**DEGREES IN MIDWIFERY.**—Dublin has begun to confer a new degree in midwifery: M. A. O., or Magister Artis Obstetricia.

**MEDICAL SOCIETIES.**—The various medical societies will resume their meetings during the present month.

**AMERICAN ASSOCIATION FOR THE CURE OF INEBRIATES** will hold its eighth annual meeting at Chicago, Ill., September 12, 1877.

**DEATH AFTER CHLOROFORM.**—An inquest was recently held in Dawlish, Eng., touching the death of Sarah Crudge, æt. 23 years, who died suddenly soon after an operation for squint, and after chloroform had been administered. Deceased was thoroughly examined by Mr. Cann, the operator, and considered a fit subject for anesthesia. Four drachms of chloroform were inhaled. After the operation deceased spoke to him and appeared perfectly right; she then fell into a sleep, her pulse being quiet and regular. In two and a half hours afterwards she was dead. The immediate cause of death was found to be effusion of blood on the brain.

**THE PLASTER-PARIS JACKET** appears to take very well, not only with the profession, but the public. Its adjustment before an audience is so easily made, and the demonstration of its usefulness so impressive, that it has found great favor with many surgeons who are lecturers and teachers. The outside public also appreciate such exhibitions. We wonder how Prof. Sayre will feel to read in a Buffalo newspaper that a surgeon of that place invited a reporter to be present at such an exhibition, and also to read a description of the operation in the said papers. But why not educate the public in these matters, and confine the treatment of such cases to hospital surgeons rather than to ordinary quacks.

**THE VISITING CORPS OF PHYSICIANS FOR NEW YORK.**—A report in relation to the operations of the Special Corps of Visiting Physicians, from July 18th to August 14th, was presented to the Board of Health yesterday. It states that they visited during the above period, with the aid of five members of the Vaccinating Corps, 23,566 houses, 131,573 families, treated 4,719 cases of sickness, and distributed 5,128 excursion tickets for the Floating Hospital of St. John's Guild. As these appointments were not all made on the same day, the average number of days occupied in the service was twenty-seven, making an average of about ninety-four visits per day for each visitor. The greater portion of sickness, of course, was found in the crowded tenements of the Fourth, Sixth, Seventh, Tenth, Eleventh, Thirteenth, Seventeenth, and Twenty-second Wards, a condition inseparable from this class of dwellings, as at present occupied; for wherever there is density of population there is a proportionate

amount of sickness, not only from the fact of there being large numbers of people within a given area, but overcrowding almost always implies poverty, want of proper food, neglect of cleanliness, increased amount of refuse, and imperfect removal of excreta. This system of house-to-house visitation is, they say, attended with many advantages to the poor.

**TRANSACTIONS OF THE MEDICAL SOCIETY OF THE STATE OF NEW YORK.**—The following letter from a country practitioner will explain itself:

"SIR—I am lately in receipt of a communication from the 'Committee of Publication' of the Medical Society of the State of New York, stating that pursuant to resolutions of the Society, adopted in '76, each permanent member is required to pay an annual assessment of two dollars (whether he takes the volume or not), and that by section second a permanent member shall not be permitted to register (at the meetings of the Society) until his dues shall have been paid. Am I then to understand, my dear editor, that, having many years ago served as a delegate from our County Medical Society, and having been admitted to honorary membership in the State Medical Society, by virtue of the laws then extant, I am forced, by an 'ex post facto law,' to contribute to the issue of the 'Transactions,' or have my name removed from the roll, be disfranchised, excommunicated, and live only in the records of the past?"

"The Society does not demand an assessment of two dollars to meet its current expenses; it simply insists that each and every permanent member shall pay a certain amount for a copy of 'Transactions,' which may be a desirable addition to their library, or not. If sundry members choose to enlighten the medical public at a costly rate, is it incumbent upon the aforesaid 'public' to pay so dearly for the 'whistle'?"

"Our 'up country' brethren are slow, patient, law-abiding men, who, whilst hailing any progressive movement, cautiously watch innovations which have a tendency to deprive them of certain vested rights, and with good reason, they are chary of the old time quotation 'sic vos non vobis.' Yours truly,

"T. E. RURE."

**HYGIEOPOLIS.**—Dr. Richardson's projected City of Health, at Courtland, England, will probably be commenced this autumn.

**QUACKS IN CANADA.**—Quacks are being persecuted in Canada. The fact of advertising in the daily papers is considered a strong point in evidence against them. In New York, however, there would be some difficulty in separating the goats from the sheep, so far at least as advertising is concerned. We would suggest to our friends across the line that they might make some exceptions concerning medical certificates for wines, mustards, mineral waters, medical colleges, and reviews of medical books.

**LICENSED MIDWIVES.**—A comprehensive scheme for the examination and registration of midwives is under consideration by the Medical Council of Great Britain.

**HOW TO DEMONSTRATE THE PRESENCE OF CARBONIC OXIDE IN THE AIR OF A ROOM.**—According to Prof. Böttcher a solution of chloride of palladium is a good reagent for carbonic oxide and carburetted hydrogen. Strips of linen or cotton soaked in a concentrated solution, as free from acid as possible, of this substance, assume an intensely black color when brought into contact with the above-named gases.

**MEDICAL INSPECTOR DELAVAN BLOODGOOD, U.S.A.,** has been detached from the Navy Yard, New York, and ordered to the European station as surgeon of the fleet.

DR. ERISMAN, the most famous of the pupils of Pottenkofer, has been sent to the seat of war by the Russian Government; he is commissioned to take charge of the disinfection of the battle-fields.

**RATTLESNAKE BITE, INDIAN REMEDY FOR.**—T. E. Wilcox, Assistant Surgeon, U.S.A., stationed at Camp Supply, I. T., writes under date of August 8, 1877:

"The following is the Cheyenne Indian method of treating rattlesnake bite:

"The wound is excised, then gunpowder placed upon it and ignited. After this the stem of chenopodium album—pig weed—lamb's quarters—mixed with tobacco (both chewed), is bound upon the cauterized wound.

"Of course the excision and cauterization are the effective agents, but the Indians are very careful to conceal the chenopodium from white men."

**HYDROPHOBIA RESULTING FROM THE BITE OF A CAT.**—Dr. Bochez, of Paul, reports a case of hydrophobia in a woman who was bitten by a cat. The animal had been shut up for twenty-four hours while in heat, and deprived during that time of food and drink. The symptoms of the disease set in ninety days after the bite. The patient died, but an infant, which she had nursed up to the moment the disease set in, continued in good health.

**A MARTYR TO SCIENCE.**—M. Alfred Deshairs, aged 34 years, Assistant to the Chair of Chemistry in the Collège de France, was recently found stretched on the floor of his laboratory in the rue Cujas, where he lived. He had been dead two days.

There is every reason to suppose that he was accidentally poisoned. Some specimens of a chemical agent, which he had long been studying, were found near his body, and it is probable that in an attempt to determine, by personal experiment, the effects of the agent, he was overcome by the poison before he was able to obtain the antidote.

**LEGAL MEDICINE.**—The Prefect of Police of Paris, after consulting with the Minister for Public Instruction, has decided to comply with the petition addressed to him by the Dean of the Faculté de Médecine, for the establishment of a course of lectures on legal medicine, to be delivered at the Morgue. The professor will be chosen by the Faculty. The lectures will be delivered twice a week from the 1st of November to the 1st of April. Only doctors and medical students of at least three years' standing will be admitted; they will be provided with untransferrable tickets.

**DISEASED MEAT.**—In the town of Würzen, in Germany, a large number of persons were taken sick last month, in consequence of eating the flesh of a diseased cow. Up to the 18th of July over one hundred persons had been affected, three of whom died. The number of victims at that date seemed to be still increasing. Those affected suffered from acute intestinal catarrh, generally with symptoms of severe cholera-merbus. An investigation of the outbreak is in progress.

**PROF. J. H. POOLEY**, of Sterling Medical College, Columbus, Ohio, has accepted the invitation to finish the course of lectures at Dartmouth, commenced by the late Prof. A. B. Crosby.

**PROPHYLAXIS OF SCARLET FEVER.**—Dr. W. H. Burt, of Chicago, believes that milk diet is a good, if not sure, preventive of scarlet fever. He has been led to this conclusion by his own and others' observations regarding the striking immunity from this disease possessed by nursing infants, and also by the fact that milk diet is a known prophylactic against lead-poisoning among those who manufacture white

lead. In children exposed to the disease he orders, according to age, from one half to a pint of milk at each meal. He believes that the cases of nursing infants getting the disease can be explained by the use of vitiated milk. He has employed his method quite extensively in cases exposed to the disease, and has succeeded in all of them in preventing the invasion.

**AMERICAN SOCIAL SCIENCE ASSOCIATION.**—The general meeting of the American Social Science Association for 1877 will take place at Saratoga, commencing Tuesday evening, Sept. 4th, with the Annual Address of the President, Mr. David A. Wells, and continuing through the 5th, 6th, and 7th, both day and evening.

Among the most interesting features will probably be the discussions on educational, industrial, social, and other questions in the Southern States, to be held by Hon. J. Randolph Tucker, of Virginia, W. L. Trenholm, of Charleston, Gen. J. M. Logan, of Virginia, Hon. Thos. P. Bayard, of Delaware, and others.

In the health department, papers will be given on Thursday and Friday, by E. G. Loring, M.D., on "Is the Intellectual World becoming Near-sighted?" F. Winsor, M.D., and others, on "Warming and Ventilation of School-houses." Mrs. A. C. Martin (of Otis Place School, Boston), on "Injury to the Health of Girls from Imperfect Early Training." A. H. Nichols, M.D., on "School Desks and Seats," and the Secretary, D. E. Lincoln, M.D., on the "Half-time System of Education."

All are cordially invited to be present, whether members of the Association or not. Those attending will be received at reduced rates by the United States Hotel; fares between New York and Saratoga will also, probably, be reduced.

**COPPER EAR-RINGS.**—While the question whether the salts of copper are or are not poisonous, was being discussed in Paris, the journal *El Criterio Médico* published two cases, which prove that the use of ear-rings made of copper may be followed by unpleasant consequences. The patients were two young girls, both of whom suffered from blepharitis, and one of them also from inflammation of the lower part of the left auricle. All the usual remedies proved inefficacious, but both the patients recovered as soon as their copper ear-rings were discarded.

**MORTALITY AMONG INFANTS IN BERLIN.**—According to the statistics of the Berlin Board of Health, the mortality among the children in that city has reached an alarming height. During the last week in June, 722 children under one year of age died, the great majority of them from diarrhoeal diseases. The mortality among children under five years of age was 852, and the entire mortality of the city was 1,055, which would give an annual death rate of 54.7 per thousand. A committee has been appointed to inquire into the causes of this excessive mortality, and particularly to examine the nature and quality of the food supplied to infants.

**REST ON SUNDAY.**—The pharmacists of Algiers have informed the public that their establishments, with the exception of six, will be closed on Sundays, from June to October, inclusive. The six that are to be kept open will be located in different parts of the city, each druggist keeping open in his turn. The addresses of the stores that are open will be placarded on the doors of those that are closed.

**DR. BUNSEN, OF HEIDELBERG.**—At the end of the coming semester, Dr. Bunsen, the eminent teacher of chemistry in Heidelberg, will celebrate his fifty-year jubilee, he having been engaged that length of time in teaching.

## Original Lectures.

## LECTURES ON DISEASES OF THE HEART.

By AUSTIN FLINT, M.D.

PROFESSOR OF THE PRINCIPLES AND PRACTICE OF MEDICINE AND OF CLINICAL MEDICINE, IN THE BELLEVUE HOSPITAL MEDICAL COLLEGE.

[Reported for THE MEDICAL RECORD.]

## LECTURE I.

## SYMPTOMATIC PHENOMENA ACCOMPANYING ORGANIC LESIONS AT THE MITRAL ORIFICE.

GENTLEMEN:—I shall next ask your attention to the symptomatic events and diagnostic phenomena connected with organic lesions at the mitral and the aortic orifice. You will please recollect that I have divided valvular lesions into three groups:

1. Those which involve more or less change in the valves or orifices, giving rise to obstruction to the current of blood.

2. Those which involve incompetency of the valves and permit regurgitation of blood; and

3. Lesions which involve neither obstruction nor regurgitation, and which are therefore innocuous.

In a practical point of view, the latter is a most important group. The signs which we have considered enable us to recognize valvular lesions; enable us to localize them, to determine whether they involve obstruction or regurgitation, or, as is not unfrequently the case, both obstruction and regurgitation. But there are lesions giving rise to signs that do not involve either obstruction or regurgitation, and for the time being, at least, are innocuous. Practically, it is important that you should take cognizance of this latter fact, and not consider, because cardiac murmurs are heard, that we have, necessarily, lesions which are of very grave importance.

There is another clinical fact which is important, namely, the valvular lesions do not produce of themselves grave results. As a general statement, this is true. The valvular lesions do not as a rule produce symptomatic events until they have led to enlargement of the heart, and it is the enlargement of the heart which stands in immediate relation with the symptomatic phenomena. Further, the valvular lesions do not produce grave symptomatic phenomena until, in the enlargement of the heart, the dilatation predominates over the hypertrophy. The hypertrophy is a conservative provision, and as long as it predominates the organ is enabled to perform its function without grave difficulties; but when the dilatation predominates, the heart becomes weakened, and then it is that we have grave results as the consequence of valvular lesions.

Let us first direct our attention to lesions found at the mitral orifice.

In this specimen, as you will see, the mitral orifice is very much narrowed; so much so as to admit but little more than the end of one finger. The heart is also very much enlarged, but the enlargement does not affect the left ventricle at all; its walls are not thickened, and its cavity is not increased in size. But when we look at the right side of the heart, there is evidently an enlargement of the right ventricle; its walls are somewhat thickened, and its cavity is dilated. We have, then, in this specimen, hypertrophy with dilatation affecting the right side of the heart, and the dilatation predominates. I know nothing of the history of the case, but it is fair to

presume that more or less of the symptoms to be spoken of to-day were exemplified during the life of the patient. Let us consider what those symptoms are.

In the first place, I will point to a general connection existing between the symptoms and the lesion. In almost all cases of valvular lesion of the heart the progress of the lesion is slow. I hardly need say to you that in a very great majority of cases they have their origin in an endocarditis complicating acute articular rheumatism. Now, for example, the patient has acute articular rheumatism, endocardial inflammation is developed, the patient apparently makes a complete recovery, and many years may elapse before any symptoms referable to the heart are developed. This is true as a general statement. What is the first symptoms which attract the patient's attention? Is it pain? No. As a rule, if we except angina pectoris, we may say that organic lesions of the heart are unattended by pain. This statement is quite opposed to the popular idea, so that we are often consulted by patients who are suffering from pain in the neighborhood of the heart, and naturally enough suppose that it indicates disease of the heart. In general the pain in those cases is due to pleurodynic or intercostal neuralgia.

The patient may have been conscious of more or less increased force in the heart's action, or palpitation, but very likely it has not attracted his special attention, even when he first comes to the physician. The heart's action has been increased in force for some time before consulting the physician, but this increase has taken place so gradually, so imperceptibly, that the patient has become accustomed to it, as a rule, and does not regard it as worthy of mention. Again, a patient with organic disease of the heart may have palpitation as a functional disorder irrespective of that disease. It is not uncommon for persons to suffer from functional disorder of the heart in consequence of anemia, etc., and under those circumstances the functional disorder may occur and have no connection at all with the organic lesion. This is an important practical point to be decided in individual cases, but I will not stop to take the question into consideration at the present time. We do not, then, find that the patients have pain, or complain of disturbed action of the heart as the first symptom of organic disease, but as a rule, that which leads them first to consult a physician is *want of breath upon exertion*.

In general, the symptoms proceeding from each kind of valvular lesion at the mitral orifice are the same. There is no special or material difference.

The want of breath upon exertion is the symptom of which the patients commonly first complain, and when they are asked how long they have suffered from shortness of breath, it will be found that perhaps they have noticed it for weeks or months. It has finally increased to such an extent that they are unable to take any active exercise without pausing, and that fact leads them to think there is something wrong, and they consult a physician. We then examine the chest, and find evidence of enlargement of the heart with mitral lesion, obstructive or regurgitant, or both. Assuming that the disease is progressing, that the dilatation ceases to hold a direct proportion to the compensating hypertrophy, the want of breath upon exertion grows more and more troublesome, and finally there is constant suffering from that symptom, even while the patient remains at rest. The reason why these patients suffer from want of breath is, that the valvular lesions prevent the free passage of blood

through the lungs; in other words, gives rise to pulmonary congestion, and in proportion as the blood flows with insufficient force it is insufficiently oxygenated, and hence the feeling of want of breath.

Following out this effect, there comes a time when the patient suffers from more or less dyspnoea constantly, is unable to lie down at night, and he suffers from great fatigue incident to the fact of being unable to assume the recumbent posture.

When the dyspnoea has reached this degree, there is one symptom which is almost uniformly present, and that is general cardiac dropsy. When we have general dropsy it proceeds usually from lesions either of the heart or kidneys; hence the division, cardiac and renal dropsy. General dropsy may occur from other causes, but, in general, when present, it depends either upon cardiac or renal disease, or upon both combined.

The cardiac dropsy makes its first appearance in the form of œdema of the lower extremities, and extends more or less rapidly, until finally the œdema becomes generalized, and we have anasarca. When this is the case there is usually more or less fluid in the serous cavities of the body.

There is a certain degree of relation between the quantity of dropsy existing in the serous cavities and that present in the subcutaneous areolar tissue; and, although it cannot be expressed mathematically, yet, in a practical point of view, the relation is certainly very clear. If we find that there is dropsy of the peritoneum, much out of proportion to the subcutaneous œdema or anasarca, we have a right to infer that we have to deal with something more than cardiac and renal disease, and probably it will be found that disease of the liver is also present.

Fortunately, there is not so much dropsical effusion into the pericardium, in connection with general dropsy, as into the peritoneal or pleural cavities. Now, this general dropsy, other things being equal, we may consider as evidence of weakening of the heart from dilatation of its cavities. To what does that stand in an important relation? It has a direct and important relation to dilatation of the right side of the heart. We have seen, and this specimen illustrates that fact, that the first effect of mitral obstructive or regurgitant lesion is to produce dilatation of the left auricle; then follows pulmonary congestion, and as the result of that congestion the right side of the heart becomes over-filled; the consequence is, an undue action is excited; hypertrophy follows to compensate, and goes on until it reaches its limit, and then dilatation takes place and increases until it becomes predominant. When this point has been reached, there is more or less dilatation of the right auricle, and then we have an obstruction to the return blood throughout the system.

The dropsy then stands in immediate relation to weakening and dilatation of the right side of the heart, and, still further, to dilatation of the right auricle.

There is another cause for dyspnoea, in these cases, other than mere pulmonary congestion. Pulmonary œdema is liable to occur. It rarely occurs in connection with mitral obstruction and regurgitation as a sudden development, but to a greater or less extent it is liable to occur as a result of the constant pulmonary congestion, and when it does occur diminishes the pulmonary capacity and increases the dyspnoea. Auscultation will enable you to determine how much pulmonary œdema is present. The pulmonary congestion leads to more or less cough and expectoration as the result of a low grade of bronchitis. In a con-

siderable portion of cases blood will be found mixed with the sputa, or the patient may have a pure hæmoptysis. It is rarely the case, however, that the bronchial hemorrhage is profuse in this class of cases.

These are the important pulmonary symptoms which stand in direct relation to mitral lesions.

Now, with regard to the *pulse* as representing the condition of the heart. It is evident, when mitral obstruction is present, that the quantity of blood in the left ventricle is considerably under that present when the orifice is healthy; hence, it is easy to understand that the effect upon the pulse would be to make it small and feeble, because of the diminished amount of blood thrown forward into the arteries. Suppose we have mitral regurgitation, then a portion of blood is thrown back into the auricle which should be sent forward into the aorta, and the effect upon the circulation is the same as with mitral obstruction. We therefore have a weak pulse as representative of mitral lesion, whether that lesion be obstructive or regurgitant. If hypertrophy predominates over dilatation, a very striking contrast is afforded by comparison of the cardiac impulse, when the ear is placed over the præcordium, with the impulse given to the finger when placed on the radial artery. The impulse of the heart will be found stronger than in health, while the pulse is much weaker. With regard to the rhythm of the pulse, we find a marked difference in different cases. In some cases, with considerable organic lesion, we have a regular cardiac action and regular pulse. In other cases, however, we find the action of the heart to be irregular, both in kind and in degree, and such irregularities are not easy to explain.

In cases in which dilatation has taken place, and there is very considerable obstruction or regurgitation, or both, we may have these irregularities, and it is important that that fact should be borne in mind. If the heart be weak as regards the force of successive systoles, we may not find a pulse which represents every systole; that is to say, the systolic contraction of the left ventricle is sometimes strong enough to produce a pulse at the wrist, and sometimes not. If, therefore, we are guided by the pulse alone, without auscultating the heart, we may be led into error with regard to the frequency of the heart's contraction. Not unfrequently we find a pulse numbering no more than 80 or 90 to the minute, when by auscultating the heart, and counting the systoles, it will be found that they number as high as 100, or 110, or 120 to the minute. In cases, therefore, in which the heart is found weak, it is important to correct the pulse found at the wrist by results obtained by auscultating the heart. When we have dilatation of the right side of the heart, producing dropsy, there is also, as a matter of course, general venous congestion, which is especially apparent in the veins of the neck; they are increased in size, and usually are turgescient. Under these circumstances, we may have venous pulsation, more frequently observed upon the right than upon the left side of the neck, and such pulsation may be present with or without turgescence of the veins. It is rarely the case that pulsation of the jugular vein can be appreciated by the touch, but it is very apparent to the eye. It is also easy to determine whether the visible pulsation is venous or arterial; for, if we make slight pressure upon the vein just above the clavicle, sufficient to obstruct the flow of blood through the veins into the heart, if the pulsation is venous it will be suspended. It may be the vein lies so near the artery that you will imagine the visible pulsation is due to pulsation in the carotid; but the amount of pressure required to obliterate it is not nearly s

much as would be required to cut off the arterial circulation.

We may go still farther, and these are nice points in physical examination.

This pulsation may be produced by the contraction of the right ventricle causing a current of blood to be sent back into the right auricle and transmitting an impulse which becomes visible in the veins of the neck. There is one way in which venous pulsation is produced, and it is called the ventricular venous pulsation. How are you to determine whether it is produced in that manner? First fix the eye upon the pulsating vein, then place the finger upon the carotid artery of the opposite side, and then observe whether the two pulsations are synchronous. If synchronous, it is evidence that we have venous pulsation, produced by contraction of the right ventricle.

Again, the venous pulsation may be produced by contraction of the right auricle. How can you show that such is the case? It is done by the same method; that is, look at the pulsating vein, place the finger upon the carotid on the opposite side, and now, if the venous pulsation is auricular, it will *precede* the pulsation of the artery, because the contraction of the auricle precedes the contraction of the ventricle.

Again, we may have two venous pulsations for one arterial, and it is easy to determine that also. It is done by fixing the eye upon the pulsating vein and the finger upon the artery as before, and then determining by count whether we have for each carotid pulse a double venous pulsation. These are the prominent events, or symptomatic phenomena, which stand in relation to disease of the heart, involving mitral obstructive lesion or mitral regurgitant lesion, or both.

As regards the other anatomical systems of the body, the excretory, the digestive, etc., these may not be very materially affected; at all events, they do not give symptomatic phenomena which are distinctive of this event.

At our next lecture we shall pass to the consideration of the symptomatic phenomena following lesions at the aortic orifice; obstruction, or regurgitation, or both, and from those pass on to the study of enlargement of the heart.

### ARE HEMORRHOIDS SALUTARY?

By WILLIAM BODENHAMER, A.M., M.D.,

NEW YORK.

THIS question, although so apparently unreasonable and inconsistent, has, nevertheless, been made one of grave importance, and is by no means so easily solved as might at first be thought, especially when we consider the fact that on both the affirmative and the negative side of the question are found some of the ablest, most profound, and most distinguished men of the medical profession, both of ancient and of modern times. I therefore approach the subject with much diffidence, and in no spirit of dogmatism. The question is certainly one of sufficient importance, for good or for evil, as to entitle it to the candid consideration and thorough investigation of the enlightened medical profession of the present day. I can do but very little more, in this brief article, towards elucidating it, than to introduce or to present it fully and fairly to the profession by giving the ancient and the modern authorities *pro et con*, so far as my reading extends, and by quoting freely from the most dis-

tinguished of these. Being well aware that this attempt will be found imperfect, I nevertheless look forward with hope that it will prove a pioneer for a more efficient laborer.

From remote antiquity it has been an opinion among physicians, and consequently among the people, that hemorrhoids are salutary, especially those that bleed; that they prevent many diseases that would otherwise happen, and that they even contribute to good health and longevity. This erroneous and pernicious opinion is held by numerous physicians and people of the present day, and is, in my opinion, a source of incalculable mischief and suffering. The error consists in giving to hemorrhoids normal or physiological attributes, and was founded upon the absurd notion entertained and taught by the ancients, that they were emunctories by which the bile was evacuated, the acrimonious phlegm, and especially the atrabile. They believed that the hemorrhoidal discharge came from the turgid extremities of the hemorrhoidal veins; and from the connection of these veins with those of the liver, they believed that they were the media through which the morbid humors, or black bile, were eliminated. Hippocrates in several of his works plainly teaches that hemorrhoids perform the office or function of evacuating the black bile or melancholic humor. He says: "In profluvio hæmorrhoidum velut quidam atribili affine cœluit." (*De Morbis Vulgaribus Liber.*) Galen also (*De Atra Bile Libellus*), and the different authorities who succeeded Hippocrates, continued to maintain the same doctrine regarding the functions which he had ascribed to hemorrhoids. Indeed, this idea was general, and prevailed until after the circulation of the blood was more fully demonstrated by Harvey, when it was in a great measure dispelled. These ancient authorities believed that hemorrhoids were the means of eliminating the *materia morbi*, or through which the *semita morbi* might be evacuated and health restored; and when they were entirely suppressed, they were, upon the principle of metastasis, determined either to the liver and produced dropsy, to the lungs and produced phthisis, or to the head and produced apoplexy. Hippocrates speaks plainly of the antiphthical effects of the hemorrhoidal discharge: "Qui sanguinem per ora venarum quæ sunt in ano, perfundere solent in neque lateris dolore, neque pulmonis inflammatione corripiuntur." (*De Hemorrhoidibus Liber.*) He also says that: "In melancholic and nephritic affections, if hemorrhoids appear, they are beneficial." (*De Judicationibus Liber, cap. vi.*) The same language occurs in Aphorism xi., section 6. Hippocrates further says: "In maniacal affections, if varices or hemorrhoids come on, they remove the mania." (*Aphorism xxi., section 6.*) All authorities agree that the author, by the phrase *maniacal affections*, means *melancholy*. Again he says: "When a person has been cured of chronic hemorrhoids, unless one be left, there is danger of dropsy or phthisis supervening." (*Aphorism xii., section 6.*) The doctrine of this aphorism, however, does not agree with that taught in his "De Hemorrhoidibus Liber," in which he says: "And make the anus red-hot and burn the pile until it be dried up, and so as that no part may be left behind. And burn so as to leave none of the hemorrhoids unburnt, for you should burn them all up." (*Genuine Works of Hippocrates. Translated by Adams. Vol. ii., p. 827. London, 1849.*) The graphic instruction here given, "to burn up all the hemorrhoids," is so diametrically opposed to that of the twelfth aphorism and to the plain and unmistakable sentiments of the several pass

ages I have quoted above, that this part of the book must be either an interpolation, or that the whole of it is spurious. Of this book the illustrious Haller says: "Although this is a spurious book, it is by no means a bad one." (*Hippocrates, Opera Omnia, Latine, ab Alberto Hallero, Vol. iv., p. 122. Lausanna, 1775, in Svo.*) Whether this book is spurious or not, I nevertheless agree with Haller that it is not a bad one, especially that part of it which advises that all of the hemorrhoids should be destroyed, and not one be left.

I have thus shown that the Father of Medicine had the most implicit confidence in the preventive, preservative, and curative powers of the hemorrhoidal disease. Galen says: "Hemorrhoids have often prevented a commencing atrabilis, or have cured it when it was established, as well as they cure induration of the spleen. They also disperse varices, gony affections, and articular pains." (*Galen, Reliquum Sciti Commentarii in Scutum Hippocratis, De Morbis Vagantibus Librum.*) Galen elsewhere says: "Those who are the subjects of hemorrhoids are much less subject to other diseases." (*De Venasectioe Adversus Erasistratum Liber, cap. v.*) Celsus considered the hemorrhoidal flux as a salutary evacuation rather than a disease. (*De Medicini, Lib. v., cap. 18, ser. 9.*)

Were it necessary, I could readily show that the doctrine of Hippocrates upon this subject was adopted by nearly all the ancients. I will now, however, show that the same doctrine, or a modified form of it, was subsequently adopted and further attested by the largest number of the moderns, such as: Plater (*Observationum in Homini, etc., Lib. i., obs. 1. Basile, 1641, in Svo.*) Primrose (*De Valgi Erroribus in Medici, lib. iv., cap. 51. Rotterdam, 1658, in Svo.*) Vega (*De Arte Medendi, lib. ii., cap. 1. Lugduni, 1576, folio.*) Zacutus (*Praxis Medica Admirabilis, lib. ii., cap. 6. Lugduni, 1657.*) Horstius (*Operum Medicorum, lib. ii., cap. 7. Norimbergæ, 1660, folio.*) Stahl (*Dissertatio de Consulendi Utilitate Hamorrhoidibus, Helmstadtii, 1704. Et Dissertatio de Hamorrhoidibus Von der Goldenen Ader, Halle, 1707.*) Alberti (*Dissertatio de Hamorrhoidibus Medicini Hypochondriacorum, Et Dissertatio de Hamorrhoidibus Longitatis Causa, Halle, 1756.*) Hoffmann (*Dissertatio de Salubritate Fluxus Hemorrhoidalis, Halle, 1708.*) Lavius (*Acta Naturæ Curiosorum, v. 1, appendix, No. 1, Ann. 1706.*) Ludolf and Breithaupt (*Dissertatio de Utilitate Fluxus Hamorrhoidalis præsertim absenti positivam curationem prohibentis, Erfordia, 1721.*) Ledelius (*Miscellanea Curiosa sive ephem. Acad. Naturæ Curiosæ, decur. iii. Ann. v., obs. 265.*) Valsalva (*Morgagni, De Sedibus et Causis Morborum, lib. iii., epist. xxxviii., art. 13. Venetiis, 1761, folio.*) The celebrated Richter cites the case of a lady who had a bleeding tumor of the right breast, which he refused to remove, believing it was caused by the suppression of the hemorrhoidal flux. He therefore proscribed remedies to restore the hemorrhoids, but with what effect is unfortunately not stated. (*Observationum Chirurgiarum, fascicul. iii., cap. 4. Gettingæ, 1770.*) Hister observes that he had seen a man, who at first became hypochondriac in consequence of the suppression of hemorrhoids, was then tormented by other symptoms which terminated in pain of the head (*Clarus*). (*Acta Naturæ Curiosorum, lib. v., observ. 161.*) Roupbach (*Dissertatio de Clavo Hemorrhoidali, Helmstadtii, 1734.*)

Almost every species of alienation has been by some attributed to the suppression of the hemorrhoidal flux. M. Esquirol says that melancholia and dementia are the most frequent (*Des Maladies Mentales, considérées sous les Rapports Médical, Hygènique,*

*et Médico-Légal. Paris, 1838.*) Larrouque (*Traité des Hémorroïdes. Paris, 1812.*) Lacoste (*Essai sur les Tumeurs Hémorroïdales. Paris, 1812.*)

Many of the authorities I have cited record numerous cases to illustrate their views as to the therapeutic value or salutary power of the hemorrhoidal flux to cure or to prevent disease, to promote continued good health, and to ensure long life. These isolated cases are all of a similar character, and do not bear close scrutiny. They only tend to prove the exception to a rule. The following is a case in point: The celebrated Professor Richeraud cites the case of a merchant who had arrived at the age of eighty-nine years, who attributed the continued good health he enjoyed to a hemorrhoidal flux which had existed for more than fifty years. So regular and so considerable was the flow, that whenever he evacuated his bowels the blood would spout out from the anus for a certain distance, as from a vein opened by a lancet. (*Nosographie Chirurgicale, tome, iv., Art. Lésions Vitales des Artères Capillaires. Paris, 1812.*) Now, the question is, was it really in consequence of this continuous daily waste of blood for fifty years that enabled this man to enjoy such good health, and to have attained to the great age of eighty-nine years? Or was it not rather owing to his naturally good and robust constitution, his great tenacity of life, and the extraordinary power of nature to restore so rapidly this daily loss of the vital fluid, which, under such continued depressing influences, preserved his life for so many years. Then how disingenuous, how illogical it is to select such an isolated case to prove that the daily continued loss of blood from the rectum is essential to good health and long life. Had this merchant followed the advice of Aëtius, by having the hemorrhage gradually arrested, and at the same time observing proper diet, exercise, and an occasional purgative, he might soon have overcome this worse than evil habit, and might have attained to the age of one hundred years. We sometimes hear it said that such and such an inebriate always had good health, and attained to an extraordinary age, although for many years he was daily under the influence of the intoxicating draught. Who, I ask, would select such a case to prove that intemperance in the use of alcohol tended to good health and long life? Some persons attain great age under the most adverse circumstances and evil influences. These are the exception, not the rule.

Now, with regard to the hemorrhoidal flux, the celebrated Stahl was of opinion that it should never be accounted excessive except when it occasioned great debility or leucophlegmatia. (*Op. cit.*) Cullen, on the contrary, was of opinion that the smallest approach towards producing either of these effects should be considered as an excess, which ought to be prevented going any further; and even in the cases of congestion and plethora, if the plethoric habit and tendency can be obliterated and removed, the flux may then with safety be suppressed. (*Lectures on the Practice of Physic, vol. i., pp. 485-932. Edinburgh, 1812.*) Riverius regarded hemorrhoids as a great evil. He says: "The immoderate hemorrhoidal flux is most dangerous, and brings on other pernicious diseases, as weakness of the whole body; coldness of the bowels, and especially of the liver; an atrophy or want of nourishment; an evil habit and dropsy by the loss of natural heat; by the spending too much blood, which is the treasure of life and the cherisher of the whole body." (*Praxis Medica, lib. x., cap. 10. Lugduni, 1657, folio.*) Galen says: "Natura evacuationi per hemorrhoides non adsue faciendâ est, quia facilè ex-

cedit et hydropem in excessu succedendo procreat." (*De Facultatibus Naturalibus, lib. iii., cap. 8.*) Ætius also remarks: "Multorum malorum causa sunt hemorrhoides, deformitatem, miseram vitam inducunt, et multos vitâ privant." (*Medici Græci contractæ et veteribus Medicis Tetra biblos, hoc est, Quateruio, Tetrah. in., sermo, 2, cap. 5. Basilea, 1542, folio.*) Ætius again observes that the danger of the suppression of the hemorrhoidal flux in plethoric habits may be prevented by the patient observing proper diet, exercise, and occasionally purging and bleeding. (*Op. cit.*) Klein says that when hemorrhoids have not caused children to perish before puberty, they often become fatal at that period. (*Interpres Cœlius, Hemorrh. Francofurti, 1759.*)

Notwithstanding the doctrine that hemorrhoids served to evacuate black bile, as held by the ancients, has long since been exploded, yet the moderns of the German and French schools continued to advocate a modified, more plausible, yet equally absurd theory. This theory, still a little more modified, is held by these schools at the present day. To show the estimation in which the hemorrhoidal disease was, and is even now, held by the Germans, it is only necessary to give some of the popular appellations which they have applied to it, and by which it is designated by them—such as "Der Guldene Flug," "Fluxus Aureus," "Flux d'or" or "Flux Doré;" or rather, "Die Guldene Ader," etc. These popular names of this affection, given by the Germans, indicate the great benefit they conceive to be obtained from it, and how precious, like gold, it is. We thus see that they worship hemorrhoids as a *pandora*, for there is not an ailment to which poor human flesh is heir, that this universal remedy, in their estimation, will not cure or prevent. Then what a blessing it is to have piles, and how unfortunate it is to be without them, or to have them cured, when they exist! The Germans may therefore, with great propriety, be considered to be the cultivators of the hemorrhoidal disease.

The French, however, are by no means behind the Germans in their laudations of the hemorrhoidal disease, for one of their ablest and best writers on this disease, the late and lamented M. De Montègre, says that "the hemorrhoidal affection might be useful to a great number of men, and that to become subject to it would for them be a fortunate event." (*Des Hémorroïdes, ou Traité Analytique de Toutes les Affections Hémorroïdales, p. 127. Paris, 1830.*)

Are hemorrhoids a disease? It remained for M. De Montègre, the author of the able and profound work just cited, to present in the 19th century the old theory that hemorrhoids are salutary, etc., in an entirely new and fascinating dress. This he does by boldly declaring that the hemorrhoidal fluxion before complications take place is no disease at all, and that it is analogous to the menstrual flux, thus making it purely physiological instead of pathological. He therefore, in order to avoid the absurdity of calling hemorrhoids a disease, and at the same time considering them healthy, says they are not a disease, but an affection. He declares the hemorrhoidal fluxion to be a vital act, to which the name *disease* is inapplicable, for not only does it not prevent or impede the exercise of any function, but on the contrary, without causing pain or notable inconvenience, it insures in a measure the preservation of the health; and in this respect it is in every sense comparable to the menstrual fluxion. "To designate this condition I will therefore," says De Montègre, "continue to make use of the word *affection*, equivalent to *manner of being*. I shall reserve the name *disease* for the cases which are aggravated by complica-

tions." (*Op. cit.*, p. 16.) In another place M. Montègre says: "In fact, the hemorrhoidal fluxion, or the ensemble of the movements by which nature produces a sanguineous fluxion at the extremity of the rectum, cannot be called a disease." (*Op. cit.*, p. 18.)

To treat M. De Montègre fairly and do him full justice, I will give his own language to the reader. He says: "Dans cet état, la fluxion hémorroïdale est un acte vital auquel ne saurait convenir le nom de maladie, car non-seulement il n'empêche ou ne gêne l'exercice d'aucune fonction, mais au contraire, sans causer de douleur ni d'incommodité notable, il assure en quelque sorte la conservation de la santé; tout à fait comparable, sous ce rapport, à la fluxion menstruelle des personnes du sexe féminin. Pour désigner donc cet état, je continuerai à me servir du mot *affection*, équivalant à *manner of être*. Je réserverai le nom de maladie pour les cas qui se trouvent aggravés par des complications" (p. 16). Again he says: "En effet, la fluxion hémorroïdale, ou l'ensemble des mouvements par lesquels la nature produit sur l'extrémité du rectum une fluxion sanguine, ne saurait être appelée une maladie" (p. 118).

Now, as it respects the sanguine fluxion to the vessels at the end of the rectum in hemorrhoids, which is the first manifestation or pathognomonic sign of the disease, and which is always passive, not active—always pathological, not physiological, I deny that it is a vital act, like the fluxion to the uterus, to which M. De Montègre compares it; but on the contrary, it is an abnormal, a morbid, or a pathological act, somewhat similar to that which takes place to the vessels of the legs, and which results in the disease called varicose veins of the legs, being remarkably like it in character. The hemorrhoidal fluxion cannot, therefore, in this respect, be compared to the menstrual fluxion, which is in every sense a vital, a normal, or a physiological act. This seems so obvious that it only needs to be stated. The idea, too, which many entertain, that the hemorrhoidal discharge and the catamenia are analogous, is absurd, for the bleeding from hemorrhoids is a hemorrhage of blood which coagulates, whereas the healthy catamenial discharge consists of the secretion of a fluid which never coagulates, and which has neither the color of arterial nor of venous blood; and in odor, too, it is remarkably distinct from that of blood, and is also very much less disposed to decomposition or putrefaction.

M. De Montègre, in endeavoring to establish his favorite hypothesis that the hemorrhoidal fluxion is physiological and not a disease, uses the term *affection* in a certain sense to designate it, thus making a wide distinction between the terms *disease* and *affection*. But this use of the term *affection* in this instance is neither sanctioned by common acceptation nor by etymology. All agree that in medical language the terms *affection* and *disease* are synonymous. He reserves the term *disease* for the aggravated complications which sometimes follow the hemorrhoidal fluxion, such as excessive hemorrhage, irritated, inflamed, or prolapsed tumors, etc. Now, with regard to hemorrhage, I would remark that it is never a disease, but the symptom merely of disease, sometimes of disease of the part from which it takes place, at other times from that of disease in remote organs. In hemorrhoids, bleeding is often absent, and when it does occur it is passive, and is a symptom merely of the disease. This disease is generally ushered in by a peculiar stinging or pricking sensation at the anus, accompanied by an uneasy and painful sense of weight, fulness, and tension about the sacrum and extremity of the rectum, often extending to the perineum and sympathetically

affecting the sensibility of the bladder, urethra, etc. These symptoms are frequently much aggravated by the pressure of the anal sphincters upon the already turgid and irritable vessels of the parts; attended often by more or less fever, with hot skin, hard pulse, and dry mouth. All these morbid manifestations may take place at the very beginning of the attack, solely in consequence of the sanguineous fluxion, and before any of the complications have taken place of which M. De Montègre has spoken, before there is the slightest effusion of blood, or the formation of organized tumors. I would now ask, how can this preternatural fluxion of blood or serum to the vessels at the end of the rectum take place without more or less affecting or disturbing the functions and the health of the organ, as well as of the whole body? Indeed, the distention of the highly delicate and sensitive vessels of the part, by any undue quantity of blood or serum, cannot for a moment occur without the patient at once experiencing, at the very beginning of the attack, many, if not all of the symptoms above enumerated. Now, if this is not disease, I ask, what is disease? *Disease*, a separation from, or a deprivation of ease; or an interruption of ease, or of the functions of the body. *Affection* (from the Latin, *affectio*, disease), Cooper says, means any existing disorder of the whole body; and by adding a descriptive epithet to the term *affection*, most diseases may be expressed. Hence we may say, *pulmonary affection*, *calentous affection*, *cutaneous affection*, *fèbrile affection* (hemorrhoidal affection, if you please), using the word *affection* synonymously with *disease*. (*Lexicon Medicum*, vol. i., p. 33. New York, 1833.)

M. De Montègre throughout his work plainly teaches that the hemorrhoidal fluxion is not a disease, but an affection. Galen, who was always very precise in defining his terms, says, when on the subject of the pulse, that he is about to treat of those pulses that are peculiar to affections (*affectionibus*) or diseases; and calls that an affection which is preternatural (*præternaturam*). (*De Præsignatione ex Pulsibus*, lib. iii.) Hemorrhoids, from their very nature, are a disease, as much so as are varicose veins of the legs. Their origin, subsequent development, and structure, prove it. The disease consists of a preternatural fulness, or decided turgescence of one or more of the vessels of the inferior extremity of the rectum, occurring at uncertain intervals, and is the first manifestation of a morbid action in them—provoked either in immediate or in remote parts—the primary cause of which it is often impossible to ascertain; hence, it may or may never be discoverable. This vascular turgidity is either the result of an increased afflux of the fluids attracted from the neighboring parts to these vessels, or it is owing to a morbidly relaxed condition of them, by which their capacity is greatly increased, and by which larger currents are permitted to pass into their cavity than normal; the fluids being solely attracted from their natural channel to these morbid vessels by the vacuum occasioned by their enlarged calibre. The natural consequence, therefore, of this morbid dilatation of these vessels, is that the circulation in them is retarded and sluggish, they having to a certain extent lost their contractile power; hence, the fluids are more or less delayed and permitted to accumulate and to distend them. If this vascular fulness or hyperæmia does not soon disappear spontaneously, or is removed by treatment, it sooner or later terminates in congestion, attended by inflammation, with a serous or semi-plastic extravasation, and subsequent infiltration into the surrounding tissues, thus laying the foundation of regular organized tumors. This affec-

tion, therefore, is, from first to last, a disease of the hemorrhoidal vessels, the arterial capillary system being principally involved. It can, therefore, with great propriety be called the *hemorrhoidal disease*.

Is it not surprising that hemorrhoids, which are so obviously a deviation from health, should by any one be considered and denominated healthy, or declared to be no disease at all? Yet many such are found, some of whom have even written volumes to prove it. But, I ask, does it sound well in reason's ear, or does it seem fit and proper in the light of common sense, to call any disease healthy, or to style it a healthy process? It can be readily understood why venesection, as a therapeutic remedy, is sometimes salutary; why calomel, rhubarb, ipecac, or opium, is salutary; for, in the administration of any of these remedies, the inference or presumption is that there exists a morbid or diseased condition of body, which requires to be relieved or removed by it.

Hemorrhoids are often the result of other diseases, such as chronic affections of the liver, phthisis pulmonalis, etc. In all such cases how absurd is the idea that they are salutary, and should not be interfered with because they tend to relieve the primary affection—the diseased organ—as a derivative remedy, nature having established them for that very purpose. Now, in my opinion, if hemorrhoids are the only hope, the only resource, the only remedy of the physician to ward off or to cure the primary disease, then indeed is the case hopeless. The primary disease as well as the hemorrhoids, the effect of it, should both be treated at the same time, for the removal of the effect will by no means remove the cause, the primary disease; and it is not the removal of the effect which produces fatal consequences, but the non-removal of the primary disease itself which results fatally. It is remarkable that the enthusiastic advocates of this theory do not, in imitation of nature, make efforts to induce hemorrhoids as a derivative remedy in cases in which they do not already exist, inasmuch as this achievement is by no means difficult to accomplish; yet we scarcely ever hear of it being done when, according to their own theory, it is of the utmost importance.

A frequent objection urged against the removal of hemorrhoids is that some patients after such operation lose their health, and sometimes die; and this circumstance alone is taken for granted as sufficient evidence that the disease had a salutary effect. Now, before such an inference can be drawn or be made available, it must first be positively shown or made known whether the frequency of the fact is such as to justify the conclusion; for no one supposes that the removal of hemorrhoids entirely exempts the patient from the effects of disease and illness ever afterwards, and no one will deny that the removal of hemorrhoids frequently leads to great improvement of the health, or that it confers substantial good. I have often heard physicians say that they regarded hemorrhoids as healthy, or that they depended upon plethora, and were, therefore, safe in warding off worse evils. In my opinion, they essentially never depend upon fulness of blood, for it is well known that they generally occur in persons of a different habit of body. The existence of hemorrhoids is no more an evidence of plethora than that of varicose veins of the legs. If one is considered healthy, or a healthy process, so should the other be. This doctrine is a serious, if not a fatal fallacy, for it leads to the entire neglect of the disease at an early stage, when it might be successfully managed and worse evils really prevented.

The fears then which are so generally entertained by so many, on the supposition that hemorrhoids are a

salutary outlet, indispensable to the constitution, and that other diseases and infirmities would be incurred by their removal, are, in my opinion, entirely erroneous and without foundation. How wrong and how absurd it therefore is to persuade the hemorrhoidal patient that his often dangerous, painful, and always disgusting infirmity is a salutary emunctory, and the very guaranty of his health!

From what has been said in favor of treating hemorrhoids as a disease, it must not be understood that the treatment, either medically or surgically, should be attempted indiscriminately, as there are sometimes conditions which contraindicate treatment; these, of course, cannot be pointed out in this brief article. There are many precautions which a prudent surgeon will observe before operating in this, as in any other case.

I will conclude by adding the following important authorities still pertaining to this seemingly inexhaustible subject, as the article would not be complete without them:

Triller (*Dissertatio de Hemorrhoidum Fluxu nunc Salutari nunc Noxio*. Viteb., 1764). De Oberkamp (*Dissertatio Fallax Hemorrhoidum Utilitas*. Heildelburga, 1781). Richter (*Censura nimie laudis Hemorrhoidum*. Gettinge, 1744). Peschel (*Epistol. de Hemorrhoidum laude circumcidenda*. Lipsiæ, 1713). Metzger (*De Hemorrhoidum statu sano et præter naturam*. Tubingæ, 1677). Perpressa (*Dissertatio de Hemorrhoidum Utilitate et Noxi*. Tolosa, 1705). Berger (*Et Vater. Dissertatio de Hemorrhoidum Fluxu Salutari et Morboso*. Iteimb., 1717). It will be seen from the numerous authors I have cited, that while some consider hemorrhoids to be salutary, others declare them to be noxious, and others, again, that they are both salubrious and insalubrious, and some even that they are no disease at all.

249 MADISON AVENUE, NEW YORK, August 20, 1877.

**DIALYZED IRON.**—Dialyzed iron is becoming very popular in this city. As usual in such cases, several preparations have appeared, which are not dialyzed, and consequently give the unpleasant taste and effect of the ordinary preparations of iron. Dialyzed iron should have no taste.

## Reports of Hospitals.

### WORKHOUSE HOSPITAL, BLACKWELL'S ISLAND, NEW YORK.

RECOVERY OF A CASE OF TETANUS TREATED BY CALABAR BEAN AND CHLORAL HYDRATE.

By S. J. HOLMES, M.D.,  
HOUSE PHYSICIAN.

I SUBMIT the following notes of a case of tetanus, which, interesting to me in its somewhat varying history, may prove such to the readers of the MEDICAL RECORD.

Lizzie M., aged 30, born in Ireland, single, of intemperate habits, was admitted to hospital July 17th. Patient, while intoxicated, attempted to step from a street car while in motion, producing a compound comminuted fracture of left ring finger, midway between second phalangeal and metacarpophalangeal joints. The wound, lacerated, with considerable loss of tissue, exposed the tendon of the flexor sublimis digitorum, and the digital branch of the ulnar nerve. Dr. C., then acting physician to the hospital, decided upon an attempt to save the finger, and resorted to cold applications continuously applied to combat existing inflammation.

I saw the patient upon my return, ten days after admission, and found the wound freely suppurating, with no attempt at union of the bone, and giving little promise of anything but loss of the member. It was extremely painful, intercepting the patient's sleep both night and day, notwithstanding free doses of opiates and chloral were given. The patient's physical condition was, however, good, and no nervous debility obtained. I ordered the wound cleansed three times per day with carbolic acid (5 per cent. sol.) in water, and applied to the wound oakum saturated in oil and carbolic acid, the whole supported by a light splint. Gave the patient chloral hydrate, grs. xv., and morphia sulph., gr. ss. each night, but found upon the following morning that she had passed a painful, sleepless night.

July 31st.—8.30 A.M. Was startled by the nurse reporting as follows: Patient very nervous, with pain (lancinating in character) referred to region of both maxilla, and stiffness, with lessened mobility of lower jaw. While the decreased movement was apparent, it was still but slight. Ordered chloral hydrate, grs. viiss. every three hours throughout the day, with grs. xv. at 10 P.M. to produce quiet and sleep.

Aug. 1st.—8.30 A.M. Patient slept but little, feels weak and uneasy, pulse 95. Temperature slightly increased, complains of cramps and pains extending from the face to neck and muscles of respiration. Jaws more rigid. Gave chloroform inhalations, a turpentine enema, and chloral hydrate as upon previous day, with opiates to control pain.

Aug. 2d.—7.30 A.M. No sleep last night. Received word that the patient was convulsed, but upon reaching her found her crying with pain (general), and all convulsion subsided, it lasting but a few seconds. The description as given by nurse was that of tetanic type, with marked episthotonus. The jaws were closely approximated, very rigid, and general pains throughout the back, legs, neck, and face. Intellect clear.

Ordered a prescription of calabar bean as follows:

R. Ext. calabar bean..... gr. xij.  
Alocohol..... ʒij.

M.

ʒi. to be given every three hours, with beef tea

milk, and whiskey, liberally throughout the day. 12.30 A.M.—Pulse 95. Temperature still increased, patient sweating and very weak, but intellect clear.

Decided to amputate, which I did, removing about one-third of the metacarpal bone. After reaction was established, ordered morphine, gr.  $\frac{1}{4}$ , every three hours until grs.  $\frac{3}{4}$  had been given, still continuing the calabar bean. Patient suffered great pain up to 3 A.M., opiates seeming to take no effect; then gave a hypodermic of morphine, gr.  $\frac{1}{2}$ , with transient relief. 9.30 A.M.—No more convulsions during the day; ordered chloral hydrate, grs. xv.

Aug. 3d.—10.30 A.M. Patient slept but poorly. No change. Weak and subject to general shooting pains. Back sore and stiff, legs cramped, pupils contracted. Calabar bean with same frequency; morphine to relieve pain. 10 P.M.—Chloral, gr. xv. 3 A.M.—Morphine, gr.  $\frac{1}{4}$ .

Aug. 4th.—Patient slept about one hour. Pulse 140, temperature 103. Jaws rigid, muscles sore, with persistent lancinating pains confined to neck and face. Patient can take nothing but liquid diet. Calabar bean continued, with stimulants (to counteract depressing effects of the calabar bean.) 12.30 A.M.—Morphine, gr.  $\frac{1}{4}$ , hypodermically. 2 P.M.—Easier. 10 P.M.—Chloral, gr. xv. 3 A.M.—Morphine, gr.  $\frac{1}{4}$ . Calabar bean every two hours.

Aug. 5th.—7.30 A.M. Slept well, and feels refreshed. No change in muscles of mastication. Pulse 102, temperature normal. Back sore and stiff, with shooting pains. 10.30 P.M.—Patient suffering great pain. Pulse 94. Jaws somewhat more closely approximated. Calabar bean, gr. ss.; sol. morphine, U. S., 5 j. 12 P.M.—Chloral, gr. xv.; 3 A.M., grs. viijss.

Aug. 6th.—10.30 A.M. Rest broken and but short intervals of sleep obtained. Patient, however, says she feels better. Muscles less stiff and rigid, and great extenuation of pain. 10.15 A.M.—Suffering no pain, but restless and uneasy. Ordered chloral, gr. xv., and calabar bean, gr. ss. every three hours.

Aug. 7th.—Patient much improved. Slept well, but still unable to take solid food. The muscles of the face undergo slight spasms in attempts at speaking. All pain in the back, legs, and muscles of respiration subsided. Calabar bean continued.

Aug. 8th.—Patient about the same. Chloral and morphine discontinued. Calabar bean kept up.

Aug. 9th.—Sleeps well, and improving.

Aug. 10th.—Patient sitting up. Takes small quantities of solid food. No pain, and feeling very comfortable. Much stronger. Calabar bean discontinued.

Remarks.—The peculiarities of the case are: the length of time elapsing after receipt of the injury to the invasion of the disease; the chronicity of partial tetanus, and the occurrence of but a single general spasm, with threatening symptoms thereof throughout the whole history of the case, giving assurance of the implication of the whole spinal motor system of nerves. While the doses of calabar bean were at no time during its administration large, they were sufficiently so to impress the system (as indicated by the contracted pupil) and to keep in abeyance general spasm.

## Progress of Medical Science.

CHANGES IN THE MEDULLA OBLONGATA AND SPINAL CORD IN HYDROPHOBIA.—At a recent meeting of the *Pathological Society of London*, Dr. Gowers showed a number of microscopical sections of the medulla and cord from four cases of hydrophobia. In all four cases the vessels of the gray matter were greatly distended, the distention being greatest in the medulla, near the gray nuclei in the lowest part of the fourth ventricle. In three of the cases the larger veins in this position presented aggregations of small cells within the perivascular lymphatic sheaths, sometimes in a single layer, sometimes densely packed so as to compress the vessels. In a few places these cells extend beyond the limits of the sheath. Similar cells were scattered through the tissue among the nerve-elements, and in some places, chiefly in and near the hypoglossal nuclei, there were dense collections of these cells, constituting in fact "miliary abscesses." Adjacent to many vessels were areas of granular degeneration. In two of the cases many of the larger vessels, chiefly veins, contained clots, parts of which were evidently of ante-mortem formation. In one specimen the inner coat of a vein was thickened opposite the older part of a clot, and there were round cells in the perivascular sheath, within the old clot, and in the substance of the swollen inner coat. The nerve-cells presented comparatively slight changes, being merely slightly swollen and in some places granular, and surrounded here and there by granular degeneration. These changes were most intense in and about the pneumogastric, hypoglossal, and glossopharyngeal nuclei; slighter in the nuclei of the auditory, facial, and fifth nerves, and in the cord; and slighter still in the upper part of the pons. Dr. Gowers concluded by alluding to the difficult question, as to whether these vascular changes were the initial lesion in the nerve-centres, or were secondary to the irritation of the nerve-elements by the blood poison. It was certain that embolism played no part in the process. The coagulation in the vessels was not essential, while in one case the absence of cell-infiltration showed that dilatation might be the only morbid change in the vessels. On the other hand, the changes in some of the clots, in cases in which the symptoms had lasted only three days, showed that considerable vascular changes must have occurred very early in the disease.—*The Lancet*, June 9th.

ON THE DEVELOPMENT OF GIANT CELLS, AND THEIR PRESENCE IN IVORY PEGS USED IN THE TREATMENT OF PSEUDARTHROSIS.—In March of this year, Dr. Aufrecht, of Magdeburg, received three ivory pegs that had been used in the treatment of a pseudarthrosis of the leg in a young man. The pegs, when driven into the bone, were each  $1\frac{1}{10}$  in. in length, and they had been left in situ respectively, one, two, and three weeks. Even microscopical examination revealed no change in the surface of the first. The second presented a rather deep, circular depression at the junction of the upper and middle thirds, and from thence to the point it was rough and eroded. Part of the circular depression was filled with a grayish white mass of tissue. The third peg was broken in the removal, the larger portion being left in the bone. The piece removed measured half an inch, and its fractured end was rough and eroded. On microscopical examination the most perfect giant cells were found in the circular depression on the second peg

A WRITING-MACHINE FOR THE BLIND.—M. Recordon, Geneva, has invented a machine by which blind people can write at once in characters meant for their blind brethren and in ordinary letters legible with the eyes. A writer in a Paris paper says that he saw it in operation, and a few phrases which he himself wrote with it, without any preparatory study, were deciphered immediately with surprising rapidity.

and on the surface of the peg from thence to the point, and also on the fractured end of the third peg. The cells lay singly or in groups, in lacunae that resembled very closely the spaces met with in the ossifying border of cartilage. At the under part of the second peg smaller and shallower depressions were found, which resembled bone corpuscles in every respect, except that the processes extending from them were less numerous. No cellular bodies were found in these depressions, perhaps because attention was not called to them until long after the peg had been received. Dr. Aufrecht regarded the depressions as the first effects of the process of resorption.

From his previous studies on giant cells in miliary tubercles, and the results of the examination of these pegs, he believes himself justified in drawing the following conclusions:

1. The giant cell originates exclusively by the confluence of the protoplasm of the cells called fibroblasts by Ziegler, *i. e.*, of the round, oval, spindle-shaped, or stellate cells, with sharply defined, usually oval nuclei, and one or more nucleoli, from which, under other circumstances in pathological connective tissue growths, the connective tissue fibres are developed. The number of nuclei in the giant cells is not greater than the number of nuclei contained in the original fibroblasts. He has never been able to find any evidence of an endogenous proliferation of nuclei in the giant cell.

2. The giant cell is met with where there is some obstacle to the change of the fibroblasts into connective tissue, or where the capacity of the cell for this new development is lessened. The giant cell that is developed in the neighborhood of foreign bodies, the irritation of which is not sufficient to excite suppuration, is an instance of the former; the giant cell of sarcoma of the latter.

3. The giant cell, in common with other cells, can bring about resorption of bone, as it brought about the destruction of the ivory pegs in the above-mentioned case. It is probable that an accumulation of carbonic acid accompanies the formation of giant cells. Now, Tillmanns has proved that carbonic acid will dissolve the lime salts of ivory, and hence the resorption of the organic substance would be the task set for the giant cell.

4. The club-shaped, closed ends of newly formed vessels, which are formed by the union of cells, that are identical with fibroblasts, may be mistaken for giant cells, when their connection with the vascular system is concealed by overlying connective tissue, etc.

Dr. Weiss, who has also been investigating the subject of giant cells, has come to the same conclusion as Dr. Aufrecht, *viz.*, that the giant cell is formed by the confluence of several smaller cells. He introduced hairs and cotton threads into the subcutaneous tissue of dogs and pigeons, and after fifteen to forty-five days cut them out with some of the tissue around them. He frequently found the foreign body in the inside of a giant cell. The cells which form the giant cell are granulation cells; irritated by the foreign body, they increase in size, become more spherical, present three or four nuclei, unite together, and gradually assume a homogeneous appearance.

Unlike Dr. Aufrecht, Dr. Weiss denies that the giant cells can be developed into blood-vessels; he states that they always finally undergo a fatty degeneration.—*Centralblatt f. Med. Wissen.*, June 30th, and *Centralblatt f. Chirurgie*, July 7th.

**A HITHERTO UNNOTICED SIGN OF IMMATURETY OF THE NEW-BORN CHILD.**—All obstetricians are familiar with the white points which stud the tip of the nose

of every new-born child. They are due to dilatation of the excretory ducts of the sebaceous follicles, and are best described as white comedones. In the course of some anatomical examinations of the sebaceous follicles in the face of the new-born child and of the embryo near term, Dr. Küstner, of Halle, had his attention called to the fact that similar white points are in many cases found on the ala of the nose, the cheeks, the forehead, and especially on the chin and underlip. These are also due to distention of the follicles by plugs of sebum, but they differ from those constantly found on the nose, and are better described as milium. He has found that they are abundant in proportion to the immaturity of the fetus, and decrease in number as full term approaches, so that only the comedones on the tip of the nose are found in the child carried to full term. He has examined twenty-nine premature children, and seventy that were born at the proper time. The former always presented other signs of immaturity as well as the milium, *viz.*, abundant lanugo, small size and weight, etc.—*Centralblatt f. Gynäkologie*, July 21st.

**TREATMENT OF SUPPURATIVE OSTEO-MYELITIS.**—Dr. Eug. Boeckel states that he regards an elevation of temperature, persisting after free division of the periosteum, as the surest sign of the existence of acute osteomyelitis. In the treatment of the affection, he recommends the use of the trephine and hollowing out of the bone. He claims that osteomyelitis is more common after the amputations than is usually believed, and that whenever a chill or an unusual elevation of temperature sets in after an amputation, the surgeon should bear in mind the possibility of the existence of suppuration of the bone. It should be examined with care, and if necessary, any newly formed adhesions between the lips of the wound should be broken up, so as to permit of a free inspection of the marrow of the bone. If this be infiltrated with pus and diffused to some distance, and if at the same time periosal phlegmons exist, it is necessary to act promptly and energetically. In the milder cases it is sufficient to empty the medullary canal by means of a gouge, and to keep up a continuous carbolic irrigation of the cavity. In severer cases the trephine should be applied at one or more spots, according to the extent of bone involved. He believes that the osteomyelitis, instead of being secondary and the result of a pyæmia, is in reality the source of the infection of the blood.—*Annales et Bulletin de Gand*, June, 1877.

**SUBCUTANEOUS INJECTION OF DEFIBRINATED BLOOD.**—Dr. Schmeltz, of Schlestadt, reports a case of consumption with great weakness and intense anemia, in which the subcutaneous injection of defibrinated blood was followed by the most satisfactory results. The patient was first seen by Dr. Schmeltz in March, 1874; he was then over sixty years of age, had been sick for a long time, and was confined constantly to his bed, in consequence of his extreme weakness. He was reduced almost to a skeleton, and almost all over his lungs there were dulness, bronchial breathing and moist râles. He had hectic, and suffered from various neuralgias, from frequent attacks of syncope, and from dyspnoea. His stomach soon became weak, and neither food nor medicines could be retained. Dr. Schmeltz then determined to try subcutaneous injections of defibrinated blood, which had been first recommended by Dr. Karst, of Kreuznach. The blood used was taken by wet cups from the back of the patient's son, and was carefully defibrinated. Eight injections of five grammes each were made into the arms and legs at one sitting, consequently forty gram-

mes (ten and a quarter drachms) in all were injected. The swellings caused by the injections had disappeared at the end of the second day. The operation was followed by a very rapid improvement in the general condition of the patient. His appetite returned; the pulse became full and firm, and 80 per minute; the neuralgias, anxiety, palpitations, and extreme weakness were relieved, and he was able to sleep. Eight days after the operation he got up, and convalescence was thenceforth uninterrupted. The patient is still living and in good health; during the last two years he has required no medical treatment.

Dr. Schmeltz thinks that this case proves that the hypodermic injection of blood may prove useful in many cases where transfusion is indicated, especially in cases of anemia in which the stomach rejects all nourishment and medicine.—*Annales et Bulletin de Gand*, June, 1877.

**TREATMENT OF BLENNORRHOIC EPIDIDYMITIS WITH IODOFORM OINTMENT.**—Dr. Alvares, of Palma (Majorca), has treated four cases of epididymitis with iodoform ointment, and from his experience in these cases draws the following conclusions:

1. Iodoform calms the pain of blennorrhagic orchitis better than any other application; this result is obtained at the end of one or two hours.
2. Iodoform exerts a very manifest resolvent action, and has the advantage over the usually employed mercurial ointment, of causing no trouble when absorbed.
3. The iodoform treatment shortens very appreciably the duration of the orchitis, and prevents any consecutive induration of the organ.
4. It is necessary to employ an ointment containing, according to the intensity of the inflammation, from one to two grammes of iodoform to thirty grammes of lard.—*Le Bordeur Medical*, June 26th.

**THE MORBID ANATOMY OF TUBERCULAR TESTICLE.**—Dr. Gaule has subjected sixteen cases of tubercular testicle to a careful anatomical investigation, and found that the pathological process consisted in a catarrh with special tendency to caseous degeneration and ulceration. The affection began in the epididymis, and spread from the epithelium to the walls of the tubes and the surrounding interstitial tissue. It extended, sometimes more within the tube, sometimes more in the interstitial tissue, first to the corpus Highmori, then to the septa testis, and finally to the convoluted tubules. It advanced with diminishing intensity towards the periphery of the testicle, either in a solid phalanx, or in disseminated masses, according to the number of tubules affected. In the latter case, fibrous nodules were often developed, which have been hitherto regarded as tubercles, but which Dr. Gaule regards as analogous to the peribronchitic nodules in phthisis pulmonum. The entire process in the testicle presented the greatest similarity to phthisis pulmonum; moreover, both affections are preceded by the same sort of diathesis, and are even usually combined in the same patient. Hence he proposes that the disease in question should henceforward be called phthisis testis, instead of tubercular testicle. Miliary tubercles are met with in the testicles, as well as in the lungs in cases of acute, general, miliary tuberculosis, but the process is then very different from the one described above.

It is true that structures which macroscopically and microscopically resemble miliary tubercles are met with in phthisis testis, and are even characteristic of a certain stage of the process. These structures, however, are not developed in the connective tissue, but are the product of a transformation of the epithelium and the wall of the tubule under the influence of the

inflammatory phthisical process. Hence, they do not constitute tubercles in Virchow's sense of the term.—*Allgemeine Med. Cent.-Zeit.*, June 23d.

**NEW METHOD OF TRACHEOTOMY SPECIALLY APPLICABLE IN YOUNG CHILDREN.**—Dr. J. J. Reid, of this city, advises the following method of operating: After the usual incision of the skin, and the division of the strong superficial fascia which connects the sterno-hyoid muscles, the knife is laid aside, and the next part of the operation performed by two uterine tenacula. With these the deep layers of fascia are torn and the thyroid veins are pulled aside, until the trachea is sufficiently exposed. The tenacula are then inserted into the sides of the trachea, and slight traction is made, while the tube is laid open to the desired extent with a bistoury. The wound in the trachea is thus made to gape widely, and any pieces of membrane can be removed and the tracheotomy tube easily introduced. The advantages claimed for this method of operating are that it reduces to a minimum the risk of hemorrhage, serves to fix the trachea without the danger of compression of the trachea and larynx, and facilitates the introduction of the tube.—*New York Medical Journal*, July, 1877.

**FOUR SUCCESSIVE RUPTURES OF THE UTERUS IN THE SAME PATIENT.**—Dr. Rose, of West Winfield, N. Y., reports this interesting case. The patient, an Irish woman, 32 years of age, and the mother of two children, was taken with labor-pains June 1, 1869. Five hours after labor began, rupture of the uterus occurred. Dr. Rose passed his hand into the uterus, and through the rupture into the abdominal cavity. He succeeded in finding the feet, which he brought down, and delivered a dead child, together with the afterbirth, which was also in the cavity of the abdomen. The operation was well borne, and was followed by but little peritonitis. Recovery was complete and rapid.

The next labor occurred in April, 1872. After three or four hours the pains suddenly stopped and the head receded. On passing his hand into the uterus, Dr. Rose found that rupture had again taken place. He delivered as before, by passing his hand through the rent in the womb and bringing down the feet. The patient was able to do light work in about a month. In May, 1874, she was again taken with labor pains, which lasted about two hours and stopped suddenly. The cessation of the pains was followed by abdominal tenderness and feelings of faintness, but the physician who attended her told her that the pains had stopped and might not come on for a week or more. Two days later Dr. Rose saw her, and found the os partially dilated and the uterus again ruptured. Both child and placenta lay in the abdominal cavity. Delivery was effected by version as before, but this time the tenderness was so great that chloroform had to be given. The child had been dead so long that the skin peeled off when it was handled. The rent was transverse and in the posterior part of the womb: "it felt as though half of the womb had been cut off with a knife." None of the contents of the abdomen escaped through the rent. Twelve days after the operation the patient was sitting up. The last labor came on on February 28, 1876. After the waters broke, the patient said that "she felt a great movement of the child—she felt it pressing up under her ribs." Twenty minutes later Dr. Rose saw her, and on making an examination was just able to reach one foot with the finger. Introducing his hand, he brought down the feet and delivered a living child. The patient suffered no more than is usual after an ordinary delivery.—*Chicago Med. Journal and Examiner*, August, 1877.

## HOME HOSPITALS.

HERE is a great deal of talk concerning the establishment of hospitals in Great Britain, for the accommodation of persons of the middle class, and who are able to pay for the services they receive. At present there seems a necessity for this movement, as it is generally understood that none but pauper patients are allowed the benefits of treatment in the large and well established hospitals in London and other British cities. There are, as far as we can understand, no private rooms for pay patients as we find in most of our large metropolitan hospitals, and the corresponding class of patients in England who would gladly avail themselves of such privileges are entirely without them, and are forced to trust to the chances of conveniences in the ordinary boarding-houses. Although we may, to a certain extent, be considered ahead of our English cousins in this particular method of providing for a certain class of our sick, there are still many things which we can learn in connection with the movement, which may be of service to us in making our system more perfect, and in expanding its benefits. For instance, in our large hospitals the so-called private patients can be treated only by the particular members of the hospital staff. Even if we assume that the practitioners connected with our hospitals are thoroughly competent men, it is obviously unfair, to a patient who may merely wish hospital accommodations, to be forced to submit to the treatment of one or other of those who may chance to constitute the hospital staff. This is certainly a custom which can work only to the advantage of the hospital medical or surgical attendant, and is to some extent a monopoly. The gentlemen who have hospital appointments not only have the advantage of treating their own private patients in this way, but the patients of theirs. It can easily be seen that the patients of the attending physician or surgeon have more than the

usual facilities, and it is not unreasonable to suppose that strange patients who may wish to have an operation performed upon them, will be induced to place themselves in the same relative position with the hospital operator.

An improvement upon this state of things is proposed for the Home Hospitals, in that each patient shall be treated by his own medical adviser. If this can be carried out, these Home Hospitals will become very popular, not only with the general practitioners, but with their patients. The former, instead of showing a reluctance in delivering their patients to hospital men, will be eager to send them to such establishments. Those gentlemen who are interested in making these institutions self-supporting are strongly in favor of independent medical and surgical attendance, while others, who view the question in the light of abstract practicability, discourage the movement. It is evident that somewhere between these two points of view the proper stand must be taken, but how the details will be worked out remains to be seen. As practitioners who are accustomed to look to our English brethren for the elucidation of many of the problems connected with hospital management, we shall be much interested to note the conclusions at which they may arrive.

There is, however, one element in the scheme which threatens its efficient working from the beginning and that is the subscription plan, with privileges of benefits in perpetuity. At present it is proposed to appeal to the public for subscriptions, and to give each subscriber a share in the management of the institution, and also the right to nominate a certain ratio of patients to the hospital. Although in any pecuniary venture it is business-like to give a *quid pro quo*, it is obviously unfair to the mechanic who can afford to pay his way in such an institution, to be hindered from entering by another who is in reality a pauper, but who chances to obtain the nomination of a rich benefactor. As the time is coming when this question of Home Hospitals will interest not only the profession here, but the public, we cannot too soon become acquainted with the details of its practical solution. At present we are willing to await in patience the practical application of the many theories which have been advanced to secure the greatest efficiency and most extended popularity.

## THE TEMPERANCE MOVEMENT.

THE attitude which should be assumed by the profession regarding any question bearing upon temperance can hardly be questioned. Fulfilling its mission to preserve the health of the people and guard against the physical effects of excesses of any kind, it should be always ready and willing to give its moral and scientific support to every movement calculated to secure such ends. At the present time there is a pressing need for the exercise of just such influences in connection with the temperance movement,

not only in this city, but throughout the land. Whatever opinions we may hold concerning the value of alcohol as a beverage and article of food, or a medicine, they should not weigh a particle in influencing our course towards the public at large. There is, perhaps, nothing more powerful in the way of an argument against the use of any article, than that it is injurious to the health, more especially if such an opinion comes from a medical man. In public and in private the physician doubtless can do much good in framing opinion in such directions, and can very effectually supplement the labors of temperance lecturers and reformers generally. That he often neglects this duty is evident to every one. In fact, not a few physicians, by the loose practice of prescribing alcoholic drinks, actually create in their patients a habit for strong drink, which in too many cases is beyond control.

It is well known that there are numbers of individuals in whom the will-power is paralyzed by alcohol; that no sooner do they partake of it than a liking for it is begotten, and then confirmed drunkenness is a question of very limited time. These persons make up the mass of drunkards, and should, as far as possible, be removed from the way of temptation, direct and indirect. With the former the physician may have much to do in the exercise of his calling as a prescriber, and with the latter, in giving countenance to any movement which may have a tendency to lessen the number of grog-shops throughout the land. We are well aware that the proper course to pursue, with all sensible men, is the middle one between the two extremes of drunkenness and abstinence; but by far the large majority of dyspsomiacs have never had the requisite amount of will-power and moral training to which any reasonable appeal can be made. With this class absolute abstinence is as a rule the only salvation. The lesser number of temptations in the shape of corner tippling-shops, "retreats," "sample rooms," and the like, the better the chance of keeping a pledge. The Society for the Prevention of Crime in this city have taken a very proper view of this matter, and are waging war against unlicensed drinking saloons, with a view of bringing their number and character within the letter and spirit of the law. This is certainly one of the very many effective means to the end, and with other similar movements, notably those of the Blue Ribbon Society, deserves countenance and encouragement.

**INFECTIOUS DISEASES AND LAUNDRIES.**—The *Lancet* commission has, in the number of that journal for August 18th, a very interesting and instructive report on the spread of infectious diseases, particularly small-pox and scarlet fever, through laundries. There is no doubt that this is the frequent source of infection when every other means of preventing the disease have been scrupulously followed out.

**MILK TAVERNS.**—As supplementary to the temperance movement in Great Britain, the establishment of milk taverns is strenuously advocated.

## Correspondence.

### THE LATE MEETING OF THE BRITISH MEDICAL ASSOCIATION.

TO THE EDITOR OF THE MEDICAL RECORD.

LONDON, August 13, 1877.

SIR:—The recent meeting of the British Medical Association at Manchester was unusually large and brilliant. The Lord Bishop of Manchester delivered an eloquent opening sermon. This was followed by the address of President Wilkinson, devoted mainly to an attack on the Manchester Infirmary, which seems to possess, in a remarkable degree, all those contrivances to secure bad air, feeble illumination, and defective drainage, which are avoided in modern hospitals. Unfortunately, the infirmary is in the hands of a Board of Governors who know intuitively a thousand times more about sanitary science than all the doctors in the world, and these governors are inexorable conservatives in the sense that fossils are.

In the evening a grand reception and soiree took place at Owens College.

The next day Prof. William Roberts delivered a magnificent address on the doctrine of Contagium Vivum, and its Application to Medicine. The British Medical Journal criticises the arguments and conclusions, but the facts and deductions presented by the able speaker seemed, in the estimation of the brighter men of the Association, to go far towards the settlement of a vexed question.

The propositions which the speaker aimed to establish are these:

1. *Organic matter has no inherent power of generating bacteria, and no inherent power of passing into decomposition.*
2. *Bacteria are the actual agents of decomposition.*
3. *The organisms which appear as if spontaneously decomposing fluids owe their origin exclusively to parent germs derived from the surrounding media.*

By his advocacy of these propositions, Prof. Roberts arrays himself with Tyndall, Pasteur, Cohn, and a host of others, against the spontaneous generative theory so vehemently championed by Bastian.

The practical application of the demonstrated propositions to pathology was very ingenious, and satisfactory proof was offered that certain of the zymotic diseases—if not all of them—originate only from germs or spores.

The Sections were well attended. The papers were limited to twenty minutes and the speeches to ten. So you see it was possible to do a large amount of good, vigorous work. Sir William Jenner presided in the Medical Section, and made a capital introductory speech.

In the evening a gay party assembled at the magnificent New Town Hall, as guests of the city authorities. In the matter of entertainments, and in the especial reception given to Americans, our British cousins have fairly outdone their well-known hospitality.

On the third day of the session, Spencer Wells gave an address on The Past, Present, and Future of Scientific Surgery. That it was able and exhaustive need not be stated in an American journal. But I mention that the eloquent delivery was worthy of the speaker and the address, and that the applause was most enthusiastic.

After the section-work, the annual dinner of the Association was observed. It began at seven and was not quite completed at half-past twelve. T

speeches were quite up to the mark of after-dinner talk. As the hours wore away, however, some of the orators became slightly tedious and incoherent. I should weary you were I to give even a list of the readable papers read in the various sections. As usual on such occasions, there was an embarrassment of riches. One could not help coveting the gift of eloquence, when, at the same hour, in different rooms, papers were to be read by Barnes, Charcot, Lund, McKnight, Chaumont, and Brunton. The best that could be done was to select almost at random. I must not omit to mention the gratifying reception given by the Association to Prof. Sayre, of your city. He has been in and about London for six weeks. During this time he has demonstrated his admirable method of treating Pott's disease and lateral curvature of the spine on more than seventy patients. These demonstrations took place at Guy's, St. Thomas', and other hospitals, in the presence of the most distinguished surgeons of the realm. The patients were of all ages, and of all degrees of deformity. Some had been cripples but a few months, others had suffered many long and tedious years. Most of the cases had been under treatment—all in vain—at the hands of the best surgeons in the land. In every instance the relief afforded by Sayre was instantaneous and marked. He was invited to attend the meeting of the Association to explain his views and illustrate his practice. At the first demonstration the amphitheatre was packed, and crowds went away unable to obtain admission. The Professor was much affected by the complimentary introduction given by Dr. Lund, but he regained his composure speedily. By his clear and emphatic statement of facts, his originality, humor, pathos, and his eloquence, he carried his audience by storm. Peals of laughter rang through the amphitheatre, and tears were brought to all eyes, and in frequent succession there were most uproarious cheers such as are possible only in a British assembly. The demonstration was a complete success. But the demand for repetition of the performance could not be resisted; the next day a new supply of patients was provided, and the Professor applied his plaster bandages and continued his lecture. He spoke an hour and a half in a manner which delighted these eminent men amazingly. They expressed their gratification in the most complimentary terms which could be employed. They declared, and with great earnestness, that Prof. Sayre by his lectures and demonstrations had effected a permanent revolution in the surgical treatment of spinal deformities, and the unanimous thanks of the association were tendered him amid applause which was little less than deafening.

At the close of the meeting, a distinguished physician of Manchester rose and declared, with a pathos which touched all hearts, that he was a living example of the manner in which spinal diseases should *not* be treated. He had been blistered and had had sulphate of copper rubbed into the raw; caustics had eaten holes into his flesh down his spine; the actual cautery had been applied; and he had suffered the agonies of the damned, without the least benefit. Had Professor Sayre's treatment been known and applied forty years ago, he would have been three inches taller, and would have been saved years of unspeakable misery. He ended by declaring that the spirit of wisdom and love which actuated his American friend and brother was the same which pervaded him who walked about an idea eighteen hundred years ago.

Adulation such as this, added to a multitude of flattering letters from grateful patients and their friends, might turn many a well-balanced head; but our

American surgeon seems anxious only that his plan of treatment should be thoroughly understood and put in practice by his professional brethren; so that, through the coming ages, spinal deformities shall not only be cured but prevented, and an amount of pain and misery and mortification be abolished which is beyond human computation.

Yours,

AMOS COTTLE.

## ENLARGEMENT OF PROSTATE.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—I am led to make some observations upon the best means of passing a catheter, in that most difficult condition which arises from enlargement of the middle lobe of the prostate, by reading the article of Dr. Squier in the *MEDICAL RECORD* for May 26th, and from having had a recent case of the kind in which I had tried to pass the obstruction with solid metallic, Squier's vertebrated, and all kinds of soft catheters. My case was one in which the globular form of the obstructing mass was such that a sulcus was formed, in the pocket of which any instrument was apt to lodge, where the obstruction was quite large and firm, and as I had the opportunity of observing in the autopsy. It will be found that something else is desired in an instrument, other than mere flexibility. You want to impart a motion almost, or quite, in an opposite direction from the line of intrusion; in other words, after the instrument has reached the point of obstruction, you want it to traverse a space towards the pubic bone, at a sharp angle from the line of entrance. To obtain this motion I selected a large-sized English flexible catheter, with steel style, which latter I curved very abruptly at the end, forming an arc of a very small circle—say  $1\frac{1}{2}$  inch. I bent the end of the style sharply inward for one-fourth of an inch, so as to force the end to hug tightly the canal of the catheter on the inside of the curve, and thus aimed, passed the catheter down to the obstruction. I then withdrew it half an inch, and with an assistant to steady the penis, held the style firmly in its position, and with the other hand shoved the catheter off the style, when it glided into the bladder freely and without the slightest difficulty. The operation was frequently repeated, and with the same result. By no other means was I able to pass any form of catheter.

By curving a style in the form I describe—as abruptly as will allow of its being introduced into the urethra—and manipulating it in the manner indicated, outside the body, it can be demonstrated that the catheter, as it is shoved off the style, comes back towards the point from which the force is applied, and hence hugs the pubic bone and traverses the tortuous passage to the bladder. It is very simple, and only needs a trial to be appreciated.

M. E. POYNTER, M.D.

MIDWAY, KY.

## A CASE OF EXTENSIVE COMPOUND FRACTURE OF THE SKULL, WITH RECOVERY.

TO THE EDITOR OF THE MEDICAL RECORD.

It would be difficult to class the following case of fracture of the skull under any of the usual headings, unless the term "smash" of the frontal bone be applied to it, as used in the surgical history of the war.

*Case.*—Enos McDonnell, æt. 35, was engaged in blasting rock, March 8, 1877. A charge which he had ignited failed to explode, and on approaching to

examine the cause, and while stooping over it, the explosion occurred. A piece of rock struck him with great force in the forehead (left frontal eminence), driving fragments of the bone before it into the brain. When I saw him an hour after the accident, he was *quite conscious*. The opening in the skull had a diameter of about an inch and a half. Some of the fragments were imbedded to a depth of an inch in the substance of the brain. I removed five large pieces and five small fragments, using the forceps and elevator. Of the five larger pieces, one measures  $1\frac{1}{4}$  by 1 inch; one 1 inch square; one 1 by  $\frac{1}{2}$  inch; one  $\frac{3}{4}$  by  $\frac{1}{2}$  inch, and one  $\frac{1}{2}$  by  $\frac{3}{4}$ . The two largest pieces are portions of the inner and outer table which fit together; they had been entirely separated by the shock.

The subsequent treatment of the case consisted of bleeding, purgatives when required, water-dressings, and careful attention to drainage and cleanliness. I had the patient to lie on his face most of the time, as hemorrhage was quite free at first, and later suppuration was profuse.

I could always tell at my morning visit if he had been lying on his back through the night: his pulse would drop to about 50 under such circumstances; generally it was regular at 60 to 65.

I found a reflecting mirror very useful in watching the granulating process within the cranium, and by its aid I was enabled to illuminate recesses in which pus was hidden, and to remove additional spiculae of bone which otherwise could not have been discovered.

The flaps were kept from falling in during the healing process by careful sutures, but on account of suppuration it was not attempted to draw them over the wound.

The cicatrix is very firm, and the man has been drilling and blasting in the mines since May, until the present strike. He has not a solitary symptom of trouble, mental or physical, so far.

J. EMMET O'BRIEN, M.D.

SCRANTON, PA., Aug. 13, 1877.

**THE GENITAL FEVER.**—In a review of Black on the Diseases of the Urinary and Reproductive Organs, in the British and Foreign Medico-Chirurgical Review for July, 1877, the following judicious observations are made:

"The 'sera juvenum Venus, ideoque inexhausta pubertas' is true still; and most healthy, manly cricket-playing lads, working students and dressers, and many young officers, really trouble their heads very little about their generative organs. It is the pasty-faced, slouching, smoking and drinking lads, who can neither look each other or any decent woman in the face, half mad and quite stupid, for whom such books as this require to be written. They will be pleased with arguments on the evils of continence, not the men who are to do the work of the world. We are no advocates for prudery or concealment: let boys be warned of sexual temptations and sexual dangers, but let them be told, when the unsavory subject has been broached, that the less they think about the state of their genital organs the better; that a nocturnal emission, now and then, is not a thing to whimper about; that the loss of mucus from a cold in the head is quite as exhausting and much more offensive; that perhaps there have been too many bedclothes, or the bedroom window has not been opened enough. Teach them to swim, box, play cricket, and speak the truth; feed them simply, and show them that smoking, drinking, and sweetmeats will spoil their training, and then books of this kind will not be so much needed, even for the profession."  
—*American Practitioner*.

## New Instruments.

### HUETER'S FLAT MALE CATHETER, AND HIS MODE OF ASCERTAINING THE DILATABILITY OF THE MALE URETHRA.

By A. ROSE, M.D.,

NEW YORK.

C. HUETER, of Greifswald, has published in the *Deutsche Zeitschrift für Chirurgie*, Bd. VIII., p. 221-225 an article entitled "Praktische Notizen zur Pathologie und Therapie der Krankheiten des Urogenitalapparates," in which he recommends the use of flat catheters. The following is a synopsis of his article:

The success obtained with Stearn's instrument for dilation of urethral stricture called Hueter's attention to the value of the flat distention of its wires; he believed this to be the reason why Stearn's dilator would pass through small strictures, when the smallest round sound, the diameter of which was less than that of Stearn's instrument, would not pass.

The common pathologic difficulties of catheterism, such as strictures and prostatic swellings, belong to the posterior division of the urethra, the pars bulbosa, membranacea, and prostatica. The shape of catheters, made of unyielding material, must be accommodated to the shape of the canal of the urethra in these parts. The meatus of the urethra is a vertical slit, which at the fossa navicularis becomes horizontal pretty large in the pars cavernosa, narrowing in the pars membranacea, without losing, however, the character of a horizontally flat slit. If the dilatability of the urethral walls was greatest in the direction of the median line of the body and less in the lateral direction, an ordinary sound might pass the slit with but little more difficulty than a flattened instrument. Hueter found the dilatability of the urethra by filling the passage in cadavere with a hardening substance, and then obtained the cast of the conduit by corrosive of the surrounding soft parts. This cast showed that the centre part of the urethra, being the largest, is also the most capable of dilatation; here the cast is round and a round metal staff will pass as easy as a flat one; corresponding with the pars membranacea, however, the cast becoming oval, or rather, as both urethral walls meet in nearly acute angles, spindle-shaped, the use of flattened catheters is indicated.

Hueter had horizontally flat catheters made of diameters in proportion of 1:2. The numbers of sizes he indicates by millimetres of width. The eyes of the catheters are at somewhat different distances from the point, one on the anterior, the other on the posterior wall of the instrument. The customary curve of the instrument is preserved.

The trial of the flat catheters in Hueter's Klinik, or different patients, gave in every respect satisfaction.

Messrs. John Reynders & Co. had the kindness to make some catheters after Hueter's plan for me, and supplied the accompanying woodcut.

I have used a catheter made according to Hueter's description, of a lateral diameter of  $8\frac{1}{2}$  millimetres

on two patients; at first, on one suffering of typhus abdominalis, whom I had to pass on twice daily to relieve retention of urine. Before having taken notice of Hueter's article I had used an ordinary metal catheter, No. 11 English; but after having used Hueter's instrument, observed that it passed through the posterior part of the urethra with surprising readiness, as was confirmed by the patient himself. The second patient is an old gentleman whose bladder is very often irrigated since several years, on account of chronic cystitis; generally with warm water, and sometimes with a weak solution of acetate of alum. Upon using the flat catheter on this patient, instead of the round one as before, I experienced also more facility of introduction. The patient was of the same opinion, and considered the instrument a valuable improvement. In both cases I found it advisable to introduce the catheter in accordance with the vertical direction of the slit at the meatus, and during progress to turn it.

Finally, I do not hesitate to give expression to my opinion that this flat form of catheters will gradually supersede all other forms as soon as it becomes sufficiently known.

### ARMY NEWS.

*Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from August 26 to September 1, 1877.*

ALDEN, C. H., Major and Surgeon. To join his proper station, Fort Townsend, W. T. S. O. 117, Dept. of the Columbia, August 16, 1877.

GARDNER, W. H., Capt. and Asst. Surgeon. To proceed to Greenville, S. C., for purpose of looking after med. and hosp. property, etc., and then rejoin his station, Allegheny Arsenal, Pittsburg, Pa. S. O. 197, Div. of the Atlantic, August 28, 1877.

FITZGERALD, J. A., Capt. and Asst. Surgeon. Upon arrival of Surg. Sternberg at Fort Lapwai, Ida. T., to transfer to him the med. property of the post, and then report without delay to the Comd'g General of the Department, in person, in the field. S. F. O. 34, Hdqrs. Dept. of the Columbia, in the field, July 22, 1877.

PAULDING, H. O., 1st Lieut. and Asst. Surgeon. Upon conclusion of summer's campaign, to accompany 7th Cav. to Fort A. Lincoln, D. T., reporting to the Comd'g Officer of that post for duty. S. O. 113, Dept. of Dakota, August 21, 1877.

HALL, WM. R., 1st Lieut. and Asst. Surgeon. Assigned to duty at Camp Macbeth, Kamiab, Ida. T. S. F. O. 31, Hdqrs. Dept. of the Columbia, in the field, July 18, 1877.

TAYLOR, M. E., 1st Lieut. and Asst. Surgeon. To proceed to Baton Rouge B'ks, La., for purpose of looking after med. and hosp. property, etc., and then rejoin his station, Wilkesbarre, Pa. S. O. 197, C. S., Div. Atlantic.

GARDNER, E. F., 1st Lieut. and Asst. Surgeon. Relieved from duty at Fort A. Lincoln, D. T., and assigned to duty at Fort Ellis, M. T. S. O. 113, C. S., Dept. of Dakota.

CORBUSIER, W. H., 1st Lieut. and Asst. Surgeon. To proceed to Chattanooga, Tenn., for purpose of looking after med. and hosp. property, etc., and then rejoin his station, Jeffersonville, Ind. S. O. 197, C. S., Div. Atlantic.

NEW YORK PATHOLOGICAL SOCIETY.—The second volume of transactions of this Society is in press, and completes the reports of cases presented in 1875, which reports are largely supplemented by those of similar cases since 1844.

CONFESSION: THE PHYSICIAN AND THE PRIEST.—*The Lancet*, in speaking of Dr. Bucknill's late address before the Association of Psychologists at Manchester, says: "The psychologists who recently met at Manchester, under the presidency of Dr. Bucknill, must have been not a little charmed by the address which they heard from the chair. The title of the address, 'Confession: the Physician and the Priest,' was alone sufficient to attract a multitude. But what shall we say of the matter under the title? We should say that to characterize it faithfully our adjective store requires a refurbish. The address was made up of merits. It was short; it was learned; it was shrewd; it was long-sighted; it was wide in literary range, extending from Tristram Shandy to Bishop Hooker, from Master Gulliver to Herbert Spencer; it was wise and guiding; it was poetical; it was witty; and as it suggested that seven hundred or so of reverend clericals are subjects at this moment for the most earnest attention of mental physicians, we may add that it was all alive with interest to those before whom it was delivered. There are three points really in the address, when its clothes are taken off, which attract special notice. It sagely tells practising psychologists that it is bad practice for them to bury themselves in their asylums, instead of going out into the world to see the general sanity of varied degree there extant. It tells the priest that at present he is not a physician, and that a comparison between obscene priestly books and medical treatises is only just when the medical books referred to are the poisonous pamphlets of the manly-vigor quacks. Lastly, it informs the priest that confessional practices are not synonymous with methods of medical diagnosis: that the physician is a naturalist, the priest a supernaturalist, and that no sophistry can bridge the abyss between them. This is plain speaking and faithful, and indeed the whole essay is a characteristic utterance by one who knows what he says, and says what he knows. We agree with Dr. Bucknill that, as things are, the distance between the priest and the physician is the distance between the natural and the supernatural. We admit also the extent of the difference. We do not, however, believe that any class of men will for ever stand on the supernatural, and for this reason we differ from him on his most important conclusion. He quotes from Descartes what we should quote also on this subject,

that "if it be possible to perfect mankind, the means of the perfection will be found in the medical sciences," in which work, as we think, minister and physician will ultimately find equal occupation, and of the same natural order."

**SKIM MILK IN NEW YORK.**—A great quantity of skim-milk is sold in New York, and yet is up to the lactometer standard of the Health Board. When specific gravity is alone relied on, it is easily seen that the removal of cream actually increases the density of the milk, and gives the best possible chance for adding water to reduce this specific gravity still more. Many milk speculators understand this, and act accordingly.

**AUTOPSY IN A CASE OF DEATH FROM LIGHTNING.**—An inquest was held at the Melbourne Hospital on the 17th February, on the body of a man killed by lightning. Dr. Hefferman's account of the post-mortem was as follows: "On removing the scalp, I found a clot of blood about an inch square over the right forehead. On the front of the right hemisphere of the brain, beneath the membrane, and corresponding to the bruise on the forehead, there was a thin layer of semi-fluid blood over an area of two and a half inches. The brain-substance was normal. There was a diamond-shaped fracture of the right orbital plate of the frontal bone, but not opposite the external bruis or internal area of blood. The right side of the heart was full of dark liquid blood, and the left side was contracted. All the internal organs were healthy." *The Lancet*.

**POPULATION OF NORWAY.**—The population of Norway in 1665 was about 460,000 inhabitants. Since 1815 it has increased about 1½ annually, and the census of 31st December, 1875, gave the number of 1,817,000 inhabitants. In the last thirty years the annual excess of births over deaths has been, on an average, 1.38 per cent. The principal cause of this is the small mortality, which, on an average, only amounts annually to 1.76 per cent. of the population—a proportion smaller than in any other European country. The mortality of new-born infants is in Norway, on an average, 11 per cent., while everywhere else it has been 15 to 20 per cent.; and it has always been less for female than for male infants. This small mortality may be due to the fact that the women in all classes of society always suckle their infants during the first year, and often much longer.

**IDROSES—FEVER AND AGUE.**—Dr. A. L. Sweet, of Long Island, writes: "I have never noticed, in the medical journals which have come under my observation, anything in regard to the use of the juniper tar soap in excessive sweating of the feet. If it is not generally known, it may be of interest to state that I have found nothing comparable to the above-named remedy for this distressing and frequently disgusting affection. I use that prepared by Caswell & Hazard, and have recently completely relieved the worst case I ever saw (the patient my brother-in-law), where the secretion was so abundant and offensive as to destroy a pair of shoes in a short time, and fill nearly the whole house with the odor."

The following prescription for fever and ague has never failed in my hands to afford prompt and permanent relief:

R. Cinchonidie sulphas. . . . . grs. lxxiv.  
Acid sul. aromat. . . . . q. s.  
Tinct. nucis vom. . . . . ℥. cix.  
Syrup simplici. . . . . ad. f. ℥. iv.

M. One teaspoonful every four hours until the paroxysms are broken, then two doses a day for a

week or more. This seems to be a small dose of the alkaloid, but in the combination it is perfectly effectual, produces no unpleasant head symptoms, and the patients are not nearly so subject to relapses as when the quinia sulphate is used.

**DEATH FROM CHLOROFORM AVERTED BY THE INHALATION OF NITRITE OF AMYL.**—*The British Medical Journal*, August 18th, says: "We have received from a physician the following interesting report for publication: On the 9th instant, I was asked by a professional friend to administer chloroform to a patient of his, from whom he was about to remove a fatty tumor, situated in the left lumbar region. The patient in question was about forty-nine years of age, married, the mother of several children, of thin, spare habit, but otherwise in good health. She was nervous, and apprehensive of the result, entreating me not to give her too much chloroform. Having previously examined the heart and found all the sounds normal, I gave her about two teaspoonfuls of brandy undiluted; and after waiting a few minutes, and placing her in the recumbent posture, I commenced the administration. The chloroform I used was Duncan and Flockhart's, upon the purity of which we can always depend. I poured a measured drachm upon a piece of lint, enveloped in a towel. I held it some little distance from her mouth and nose, and let her inhale slowly. My friend noted her pulse, whilst I carefully watched the respiration. The first dose did not produce any effect, and I then used another drachm, which soon caused a good deal of excitement, incoherent talking, and struggling—the patient striving several times to snatch the inhaler from my hand. This gradually subsided, and she appeared to be passing into the third stage of anaesthesia, when she made an abortive attempt to vomit, raised her head from the pillow, and, to my friend's great alarm, the pulse flickered and stopped altogether; she gave a gasp; foam gathered on her lips; her jaw became rigid; and to all appearance she was dead. I immediately withdrew the chloroform; my friend dashed some cold water on her face and pulled her tongue forward, whilst I commenced artificial respiration, after Marshal Hall's method, but without success. We then poured some nitrite of amyl on lint, and held it to her nostrils. In such emergencies, it is impossible to judge the flight of time correctly; but I should say in ten seconds there was a flushing of the face, the pulse was again felt, and, to our great joy, the all-important function of respiration was again restored, the woman being rescued apparently from the very article of death. After a time, the anaesthesia seeming tolerably profound, my friend proceeded to remove the tumor, which he did in a rapid and skilful manner, whilst, as the patient grew restless, I gave an occasional whiff of chloroform. It proved to be an ordinary fatty tumor. Only one small vessel required to be ligatured. The wound has since healed rapidly, and the patient has made a good recovery. In looking at the order of symptoms, I cannot help forming the opinion that, had it not been for the nitrite of amyl, this poor patient would assuredly have died. I have never seen, either in surgical or obstetrical practice, any one in such imminent peril. I am thankful to say I have never witnessed a case of death from chloroform; but, from the accounts published in the medical journals, both I and my friend inferred that, in the present instance there was syncope arising from paralysis of the heart and that this was met by the nitrite of amyl, which in accordance with its physiological effects, gave a direct fillip to the arrested circulation."

## Original Lectures.

## LECTURES ON DISEASES OF THE HEART

PROFESSOR OF THE PRINCIPLES AND PRACTICE OF MEDICINE AND  
OF CLINICAL MEDICINE, IN THE BELLEVUE  
HOSPITAL MEDICAL COLLEGE.

[Reported for THE MEDICAL RECORD.]

## LECTURE II.

SYMPTOMATIC PHENOMENA ACCOMPANYING ORGANIC  
LESIONS AT THE AORTIC ORIFICE—ENLARGE-  
MENT OF THE HEART.

GENTLEMEN:—To day we will study the symptomatic phenomena following lesions at the aortic orifice. These lesions are aortic obstruction or aortic regurgitation, or both combined. In the first place, what is the effect produced upon the heart itself by these lesions? They lead first to hypertrophy and then dilatation of the left ventricle. We have in this specimen a very good illustration of the effect produced upon the left ventricle by organic lesions affecting the aortic valves. There is, as you see, a contracted and rigid condition of the valves, the walls of the left ventricle are hypertrophied, its cavity is dilated, and the dilatation evidently predominates. It is probable that there was, present during life evidence of both aortic obstruction and aortic regurgitation.

Now what were the symptomatic phenomena probably afforded by such a case as this? A patient is more likely to be conscious of undue force of the heart's action when the left ventricle is hypertrophied than when the ventricular hypertrophy affects the right side of the heart. It is not uncommon, therefore, for persons having aortic lesions and hypertrophy of the left ventricle to complain of suffering from increased force of the heart's action, and direct the attention of the physician especially to that symptom. It is frequently the only occasion for consulting the physician. Lesions at the aortic orifice do not, for a considerable period, lead to the production of dyspnoea. So long as the hypertrophy predominates over the dilatation there is usually no complaint of difficulty of breathing; but when dilatation begins to predominate over hypertrophy, the patient is conscious of an undefined sense of oppression, which is referred to the præcordium. It is not exactly dyspnoea; it is rather an indefinite feeling of distress and discomfort. This fact will lead you to make the necessary physical examination to determine whether cardiac disease is present, and, when made, the physical signs of aortic obstruction or regurgitation, or both, are found.

We will now suppose that the disease progresses, that the dilatation becomes greater and greater, yet these patients rarely have dropsy.

Dilatation of the left ventricle, in itself, never leads to dropsy. It may occur in the course of disease resulting from left ventricular enlargement; but as a general statement, if the lesions are confined to the aortic orifice, and their enlargement by dilatation is chiefly in the left ventricle, we do not have dropsy. The patients suffer more and more of this indefinite discomfort referable to the præcordia, and by and by this increases beyond that degree which is expressed by such terms as discomfort or sense of oppression. Upon taking active exercise, or from the influence of mental emotion, etc., the heart's action is unduly increased, and what is the result, assuming that the left ventricle is dilated? This cavity becomes filled with

blood, and its walls have not sufficient power to empty it fully.

Now the patient is in a certain amount of danger; the distress is very great, and there is a feeling of impending death. This is the condition of the heart, which involves the liability to sudden death. When sudden death occurs from heart disease, the lesions, as a rule, are aortic, and especially involve regurgitation.

When, therefore, we have evidence of abundant regurgitation at the aortic orifice, and dilatation of the left ventricle, we must always consider that the patient is in more or less danger of sudden death. This is a common termination, unless death is due to some intercurrent affection. We do not have dropsy or dyspnoea, or any distinctive and marked affection of the nervous system, or the digestive system, but there is danger of sudden death from over-exercise. The cause of the sudden death is paralysis of the left ventricle from over-distention. It is easy to understand how this takes place.

As a rule, patients with mitral lesions do not die suddenly. The common idea is that all persons having disease of the heart are especially liable to sudden death. But that is true only with regard to aortic lesions involving free regurgitation.

What effects upon the circulation, as shown by the pulse, do aortic lesions produce? They are usually well marked. In proportion as we have aortic obstruction it is very obvious that we should have a feeble pulse. Aortic obstruction is of much less frequent occurrence than aortic regurgitation, and the effect produced upon the pulse by the latter is quite characteristic. The characteristic features have been recognized for a long time, and the pulse has been designated by a variety of terms. It is the pulse of unfilled arteries. We have two currents of blood coming together, and the effect of that is to give a *jerk* character to the pulse, and that term is perhaps as expressive as any other which has been used. The artery strikes the finger with a certain degree of force, although it is not forcible. The quickness of the stroke gives an impression of force, and when the stroke is made the artery appears to recede immediately. In situations where arteries of some size can be seen, for example, in the neck, the vessel seems, at each pulsation, to move over a greater space than normal, and the movement is quick, as if the stroke was instantly received.

Of course, you are not to confine yourselves to this symptom in making a diagnosis, although it is highly characteristic. This peculiar jerking character of the pulse as recognized by the touch is supported by the tracings of the sphygmograph. There are so many difficulties attending the practical application of this instrument, however, that I will not now stop to give it reference. These are the more important diagnostic or symptomatic phenomena which stand in relation to organic lesions at the aortic orifice.

I would say with regard to the urine—and it is an important point—that in *mitral* lesions, which involve more or less general congestion throughout the system, it is very common to find evidence of a certain amount of albumen as the result of a congested condition of the kidneys. It does not necessarily indicate any disease of these organs beyond the congested state in which all the organs of the body to a greater or less degree are placed. The amount of albumen is always slight. If there is a considerable quantity of albumen present in the urine, it may be regarded as evidence of something more than mere congestion of the kidneys. We do not expect to find casts of the uriniferous

tubules which constitute important evidence of renal disease under other circumstances.

I may mention one point in regard to the urine which has relation to organic disease of the heart in general, but more especially to mitral lesions. The peculiar distress attending aortic lesions gives the impression to the patient of sudden death in some instances, but not in all.

In mitral lesions, however, even when there is considerable embarrassment of respiration and dyspnoea, the patients, as a rule, are not very anxious with regard to their condition. There is a remarkable difference in cases of organic disease and cases of purely functional disease of the heart, in respect to purely mental effects.

As a rule, patients who have a purely functional disturbance of the heart, have great mental disturbance; whereas, in patients with mitral lesions, and suffering more or less from dyspnoea, with a frequent, feeble, and perhaps irregular pulse, there is an entire absence of the anxiety and apprehension present with functional disease. I am not able to explain why such differences should exist, but it is a well-established clinical fact.

#### ENLARGEMENT OF THE HEART.

Before proceeding to consider enlargement of the heart, I must state certain anatomical points which are necessary to be borne in mind relating to the boundaries of the præcordia. The præcordia is divided into two portions, according to the relation which it has to the lungs. In a portion of the præcordia the heart is in contact with the walls of the chest; in the remaining portion the heart is covered with lung. These two portions of the præcordia are known by the terms, deep and superficial cardiac spaces. The superficial cardiac space is that in which the heart is uncovered with lung; the deep cardiac space is that portion of the præcordia in which the heart is covered with lung. It is desirable that you should recollect the boundaries of the superficial cardiac space, and the rule for finding them is the following. This rule is not absolutely correct, but it is sufficiently so for all practical purposes:

If you take a point in the median line, on the sternum, on a level with the costal cartilage of the fourth rib, and draw an oblique line from that point to the situation of the apex beat in the fifth intercostal space, and regard it as the hypotenuse of a right-angled triangle, you have with sufficient accuracy by such triangle marked out the boundaries of the superficial cardiac space. This is not exactly accurate, because the anterior border of the left lung, as it covers the heart, does not make a perfect oblique line between the two points given, but it answers all practical purposes.

The normal situation of the apex-beat must also be recollected. As a general rule, it is found in the fifth intercostal space, and a little within a vertical line through the nipple. This is the position normally occupied by the apex-beat, assuming that the person is sitting or standing. In the recumbent posture the apex-beat may rise as high as the fourth intercostal space, and there are occasional cases in which it can be felt at that point while the person is in the upright posture.

Practically speaking, the base of the heart is at the second intercostal space near the sternum. In reality this is just above the base, but it is in this situation that the sounds produced at the aortic and pulmonary orifices are best studied, either in health or disease. You now have the upper and lower boundaries of the

space in the chest occupied by the heart, its base and apex, and in addition it is important to memorize the two lateral boundaries of the organ. The right lateral boundary is represented by a vertical line situated about a finger's breadth to the right of the right margin of the sternum. The left lateral boundary is at or a little within a vertical line passing through the nipple.

These boundaries also are not strictly accurate for all cases, for the bulk of the heart varies within certain limits in healthy persons. They approximate accuracy, however, sufficiently for all practical purposes.

We have now studied the physical signs which represent valvular lesions of the heart, and the symptoms which are associated with organic lesions at the mitral and aortic orifice. In our study we have had occasion to say that organic lesions at the mitral or aortic orifice do not directly lead to grave results. They lead to grave results only indirectly, and the intermediate condition is enlargement of the heart; first, by hypertrophy, and second, by dilatation. Still farther, the enlargement by hypertrophy is, comparatively, unattended by grave consequences. The hypertrophy compensates for the difficulties interposed in the circulation arising from the valvular lesion. It is the dilatation which more especially, and chiefly, stands in relation to the important events and symptoms observed in connection with organic disease of the heart.

I have not spoken of the means by which we determine whether hypertrophy or dilatation of the heart is present, and it is to the consideration of that topic that I shall next direct your attention.

The questions are: What are the means by which we determine whether enlargement of the liver is present? Having determined its presence, what are the means by which we determine the degree and kind of enlargement? I shall not dwell upon these questions to-day, but shall consider them somewhat in detail at the next lecture. A few points, however, will be referred to in connection with the case before us, which is said to be a very good illustration of enlargement of the heart.

In the first place, the situation of the base of the heart, in cases of enlargement, is but little, or not at all, changed. The increased space occupied by the heart is, therefore, downward and to the left and right. The increase, however, is much more towards the left than towards the right, even when the cardiac enlargement is very great. In a case of enlargement, then, we may expect to find the apex-beat lower than natural, and carried more or less to the left; the distance in each instance being affected by the degree to which the organ has been increased in size, and the part of the heart in which the enlargement predominates. When the enlargement predominates on the left side of the heart, other things being equal, the apex-beat is lowered without being carried far to the left; whereas, if the increase in size be mainly upon the right side of the heart, the apex-beat is carried more to the left than downward. The first thing, then, to be determined in examining a given case, suspected to have enlargement of the heart, is to ascertain what relation the apex-beat has to the normal position.

If you will look at the anterior part of the chest of the patient before you, the impulse of the heart can be seen, as is not infrequently the case. You will also notice that there are several points, in the neighborhood of the apex, at which there is a visible pulsation. This also is nothing uncommon, and there may be an impulse from the apex to the base in each intercostal space. Under such circumstances, unless due care is taken, there is a liability to error in determining the

exact situation of the apex-beat. We may have a strong impulse above and a weaker impulse below, and if your attention is not attracted to that point, you may say, "Here is the apex," whereas it would be not at the situation of the upper and stronger impulse, but below or above, as the case may be.

The lowest impulse is frequently weak as compared with the impulse above, and it is for this reason that when the heart is enlarged, especially in the left ventricle, the form of the apex undergoes considerable change, and the result is that the impulse at the apex is weak, whereas the impulse produced by the heart is strong.

You will then find the lowest impulse, which, in his case, is in the sixth intercostal space, and about one-half an inch to the left of a vertical line passing through the nipple. The heart in this case occupies an increased space downward and to the left, and the extent to which it is lowered and carried to the left is a very good criterion as to the degree of enlargement; the enlargement here being well-marked, but not extensive.

In the next place, in enlargement of the heart, the precordial dulness will be increased in area and increased in degree. Why do we get this increased dulness, both in area and in degree?

It is because, in proportion as the heart is enlarged, it uncovers itself and pushes away the anterior border of the left lung. The amount of increased superficial cardiac space thus obtained carries with it an increased degree of cardiac dulness corresponding to the amount of lung removed. As we percuss over the precordia in this case, it is easy to determine that the area of dulness is increased, and when we compare it with the dulness obtained by percussing in the same region in a healthy chest, it is readily perceived that the dulness is increased in degree. These are all the means necessary to be employed to enable us to determine whether enlargement of the heart is present, and they are very simple in character and easy of application.

Now, as to the kind of enlargement. Which predominates, the hypertrophy or the dilatation? This question, also, is very easily settled. What are the points by which it is determined?

First, we have the evidence afforded by palpation. In proportion as hypertrophy predominates over dilatation, the action of the ventricles is strong, and in proportion as dilatation exceeds hypertrophy, the cardiac impulse is weak. As I apply my hand to the precordial region in this case, it receives a strong saving impulse, communicated through the thoracic walls. This alone is, as a general rule, quite a certain means of determining whether, in the enlargement, it is the hypertrophy or the dilatation that predominates. There is, however, another and more sure method of answering this question, and that is by means of the stethoscope. Place the instrument over the heart and determine what is the character of the first sound. In proportion as the heart is hypertrophied, we have the first sound intensified; all its characters are more marked than in the normal sound. In proportion as dilatation predominates over the hypertrophy, we have the first sound divested of all its distinctive characters, and it has acquired the valvular, clicking character. In some cases the second sound of the heart may be even louder than the first. In this case the first sound is intensified and is booming in character.

We have, then, evidence of enlargement of the heart, and also of the degree and kind of enlargement. To complete the case, let us determine whether the patient has enlargement associated with valvular lesion. There is such lesion, as evidenced by the

presence of an aortic direct and a mitral regurgitant murmur. The subject of enlargement of the heart will be farther considered at our next lecture.

## THE NATURE AND TREATMENT OF NEURASTHENIA (NERVOUS EXHAUSTION), HYSTERIA, SPINAL IRRITATION, AND ALLIED NEUROSES.

By GEORGE M. BEARD, M.D.

THERE is a large family of functional nervous disorders that are increasingly frequent among the indoor classes of civilized countries, and that are especially frequent in the northern and eastern parts of the United States, but of which our standard works of medicine and our lecture-rooms give little or no information. This family of diseases—or of symptoms, if we prefer to call them such,—include *neurasthenia*, or nervous exhaustion, *cerebral irritation* (cerebrasthenia), *spinal irritation* (myelasthenia), constitutional *neuralgia*, *sick headache*, *nervous dyspepsia*, *physical hysteria* (as distinguished from *psychical or mental hysteria*), *hay fever*, *inebriety*, and *pathophobia*, or morbid fear, in its different varieties, as *agoraphobia*, or fear of places, and *astrophobia*, or fear of lightning.

The sufferers from these maladies are counted in this country by thousands and hundreds of thousands; in all the Northern and Eastern States they are found in nearly every brain-working household; and yet one might graduate at all of our colleges, read all of our most-used medical treatises, and converse with the majority of our ablest practitioners, without obtaining any just ideas in regard to the nature or treatment of these maladies. Even when these affections are treated of at all, usually it is one-sidedly, partially, and erroneously. Thus, neurasthenia is confounded with anæmia; spinal irritation is confounded with spondylitis or spinal congestion, or is attributed to mere circulatory irregularities, as anæmia or hyperæmia; sick headache is regarded as a disease of the stomach, and treated with antacids and purgatives; physical hysteria is stigmatized as a malady of the imagination; hay fever is supposed to be parasitic or infectious; inebriety is mistaken for drunkenness; while cerebral irritation and the different varieties of morbid fear are not mentioned at all.

Conversing on the subject the other day with a very intelligent interne of one of our largest hospitals, I found that neither in the medical school nor in the hospital had he received any suggestions relating to any of these functional diseases of the nervous system, although, if he should ever engage in private practice among the better classes of any of our larger cities, he will meet these diseases every day and every hour, and his success will depend to a considerable extent on his success in managing them.

Various causes combine to keep these functional nervous disturbance from being understood and recognized in medical schools and literature. They are but little known in Europe, whence until recently nearly all of our medical works have been obtained. They are not found in hospitals or dispensaries, and so do not afford material for clinical lectures to students. They are comparatively recent maladies, and there has been scarcely time to exhaustively observe and unify their symptoms. All these diseases are symptoms of impoverishment of the nerve-force, and are the results of the drafts made on the vital energies by the increase of work and worry, under the stimulus of the telegraph and railway and the periodical press.

These disorders are transmissible oftentimes, taking

the place of each other. They run in families more demonstrably than scrofula, or cancer, or consumption. Indeed, one great cause of the rapid increase of these disorders during the first quarter of the century has been inheritance. It is not difficult to find families in which all these diseases are represented; and there are individuals who at different times, or at the same time, suffer from all or nearly all of them.

I have said that in Europe these affections are but little known; but, in liability to them, all the European countries are not alike. They appear to be least common in Germany and Russia, Italy and Spain; considerably more frequent in France, and more frequent still in England. A good type of this family of neuroses is hay fever or inebriety, and it is observed that both of these disorders are incomparably more abundant in the United States than in any other country, where, indeed, they have alone excited wide attention. In England, and even in France, these same diseases are now beginning to arouse public interest, while, in Germany and the rest of Europe, the existence of such diseases is scarcely suspected, or credited even by the leaders in the profession.

Although these difficulties are not directly fatal, and so do not appear in the mortality tables; although, on the contrary, as I have many times pointed out, they tend to prolong life and to protect the system against febrile and inflammatory diseases, yet the amount of suffering that they cause is enormous. Volumes are written on typhoid and other fevers; but in this country these neuroses, although not fatal, cause more distress and annoyance than all forms of fever combined, excepting perhaps those of a malarious origin. Fevers kill, it is true, while these neuroses do not; but to many death is by no means the most disagreeable of the many symptoms of disease. A cyclopaedia of medicine, adapted to the wants of the practitioner in the northern and eastern parts of this country, should contain a full volume devoted to these diseases; and yet, so blind is our deference to Europe, so fearful are we of making our own independent, original observations of the maladies peculiar to this land, and so completely are we tethered to hospital and dispensary experience, that up to the present time there is no monograph even on these diseases, and all attempts on the part of experts to study them, or to diffuse a knowledge in regard to them, are met at every step with inappreciation or positive opposition. If this family of diseases is to be studied at all, it must be in this country, where the material in vast and increasing abundance is to be found. If we depend on Europe, or on hospitals and dispensaries that are patronized mostly by European peasantry, we shall never know anything about these disorders. The position of European physicians in regard to these maladies may be understood by one or two facts. Niemeyer doubts the existence of spinal irritation, a condition which among the better classes of American women is almost as common as headache or hemorrhoids. Two very friendly English critics, noticing my work on hay fever, expressed sincere regret that I should spend my time and force on so trifling a subject; and yet the 50,000 victims of that disease in this country—probably five times more than in all the rest of the world—are as much in need of relief as the victims of rheumatism, or neuralgia, or malaria; and there are few diseases that offer greater difficulties and complications to the student, or that have been obscured by more false reasoning.

These diseases I bring into one family, because they have a common pathology, a common prognosis, a common history, and a common treatment. They all

occur under similar conditions and in similar temperaments. They are all diseases of civilization, and of modern civilization, and mainly of the nineteenth century, and of the United States. They are to be distinguished from certain other nervous diseases oftentimes regarded as functional, as chorea, writer's cramp and epilepsy, and psychical hysteria, and especially are they to be distinguished from unquestioned structural or congestive diseases, such as locomotor ataxy, progressive muscular atrophy, tetanus, and apoplexy, all of which diseases are probably thousands of years old, are not restricted to civilization, though more frequent in civilized countries, and are as common in Europe as in America, if not more so. These organic or structural nervous diseases all occur chiefly in the strong or comparatively strong; they are not diseases of nervous debility, and abound more among the muscle-working than among the brain-working classes.

The general pathology of all of these affections is undoubtedly *malnutrition*—circulatory disturbances, anæmia or hyperæmia, local or general, being secondary. In the pathology as well as physiology of the nervous system both nerve-force and blood are indispensable, and act and react on each other; but if either comes first, it surely must be the nerve-force, which originates in the nerve-cells. When the nerve-tissue is exhausted from any cause, we have neurasthenia, which may exist even where there is no anæmia, and which may be entirely independent of the circulation, although it usually affects it more or less and is affected by it. The long-mooted question of the pathology of certain of these diseases, as sick headache and spinal irritation, is thus seen to be much broader than has been supposed, and includes the pathology of this whole family of diseases.

These affections have a common prognosis in these respects, namely, that they do not necessarily shorten life, that they keep off other and more serious and fatal diseases, that they run into each other, and are all transmissible.

This family of maladies has in general a common therapeutics; all are to be treated on substantially the same general principles—the wise use of tonics, sedatives, and stimulants, varying the manner of administration and the special form according to the peculiarities of each case. To trace out each special symptom and treat it alone is unphilosophical and usually unsuccessful, save for temporary relief. The sedatives and tonics on which I mainly depend are electricity in the form of central galvanization and general faradization, massage or rubbing and kneading of the muscles, cod-liver oil in emulsion or glycerine, phosphoric in some of the various preparations (phosphoric acid in the oil emulsion, or phosphide of zinc), strychnine, arsenic, and iron. For some months past I have been using protogon with some apparent advantage. Special symptoms and state and general irritability are combated by bromhydric acid, bromide of camphor and the other bromides, and caffeine; counter-irritation, by the actinic cautery and by *very small* blisters on the nape of the neck and spine, is of great value, and may be used in such a way as to cause little pain or annoyance. Calabar bean as a spinal sedative, and gelsemium neuralgia, are to be commended.

In the hygiene of this class of cases the great factors are *rest, food, and mental diversion*. The rest should sometimes be absolute; society and physical exertion as well as mental exertion, are sometimes to be interdicted. The error of over-exercising, of walking, running, climbing, rowing too much, is a very common

me with this class of patients. Salvation from these maladies is not usually wrought by such violent procedures. The quality of repose—needed everywhere, but especially in this country—should be taught by the physician and practised by the patient. The suggestion of Dr. Mitchell to keep these patients in bed for a long time may sometimes be carried out with advantage. Sufferers of this kind do well to study the art of taking it easy; their vacations should be spent tentatively in elaborate inactivity, for muscle as well as mind requires rest. The food of the neurasthenic should be abundant and varied; meats of different kinds, fruit, fish,\* and milk where it agrees, being important. There is no danger that nervously exhausted patients will eat too much; there is every danger that they will eat too little. Even in nervous dyspepsia frequent and palatable meals are to be enjoined; and sometimes it is well to eat a little a dozen or more times a day, never filling or overloading the stomach, and never allowing it to be empty. Moderate lunches between meals I often advise, and also eating just before retiring or late in the evening. Better to eat too much, better to eat proper food, than to eat too little. The habit of eating fat meat should be cultivated; and it is noteworthy that this class of patients, like consumptives, are apt to dislike fat, and to find difficulty in digesting it.

*Camping out*, for those who understand the art or are able to learn it, is to be commended most earnestly as the best possible antidote at our command for the physical evils of civilization. The clothing of the nervously exhausted should be much warmer than is usual, two thicknesses and even three thicknesses being sometimes required during the coldest weather. Sea voyages and mountain air, or, what is better still in some cases, an alternation of sea and mountain, is one of the very best adjuvants to other treatment. It is well, for those who are benefited by both influences, to spend a portion of their vacations at the sea-side and a portion in the mountains, and to go from one to the other at short intervals.

Patients of this class need to be reminded that they must not always expect immediate benefit from travel or change of air. During their vacations they may be worse, or, at least, no better; the fatigue of motion and the discomforts of hotel and travelling arrangements, and the irregularities of meals, may at first and for a long time mask the real recuperative forces that are working in the system, and produce discouragement. But on return home the sedative and tonic effects of the vacation may be felt for weeks and months and years. The after-effects of vacations, like the after-effects of electrical and other treatment, are worthy of much study.

These diseases are usually amenable more or less, and sometimes very decidedly, to mental therapeutics to the influence of the emotions of hope and special finite and limited expectation. The prognosis in any case is closely interwoven with the psychology of the patient. The man of feeble resolution, moderate intellect, and who sees only the dark things in life, will remain an invalid where the man of grit and

courage and hope would rapidly recover. The expectation that a certain course of treatment, whatever it may be, will have a certain effect in a *specified time*, has itself a tendency of the strongest kind to produce that very effect in that time. The science and art of exerting such definite and limited expectation so as to lead the patient by his own mind, step by step, towards recovery, requires much study and experience. The simple promise of recovery or general encouragement is not enough; there must be a limited and specified task for each day or week or month. Health, like a house, is to be built, not all at once, but brick on brick, one at a time. Specifically the patient should aim to get rid of a single symptom at a time, or to make a certain percentage of improvement each week or month. Certain functions, as sleep, appetite, and digestion, are wonderfully under the influence of definite expectation. Mental therapeutics may be systematically combined with any one or the other forms of objective treatment, and when so combined will greatly increase the quickness and number of the recoveries. I will illustrate these principles by a few cases:

#### 1. HYSTERO-EPILEPSY AND SPINAL IRRITATION—VIOLENT AND VERY FREQUENT CONVULSIONS—RECOVERY.

Miss N., aged 18, was referred to me by Dr. C. L. Mitchell, under whose care she had been for some time, and who had treated her case with excellent judgment, though not with satisfaction. In speaking to me of the patient, he described her as an "*awful case*." I found on visiting the lady that the description was accurate. On the slightest irritation, mental or physical, she would go off into violent convulsions that would last all the way from five minutes to half an hour or more. An unpleasant remark, a trifling dispute, the slamming of a door, or any unexpected noise, near or distant, the entrance of a stranger, the lightest touch on the middle dorsal vertebrae between the shoulder-blades, and the contact of any hard substance against any part of the body, the shock of taking a dose of medicine oftentimes, would throw her into convulsions, which, according to circumstances, were repeated from twenty to perhaps two hundred times daily. In these attacks the eyes would be turned up and closed, the head turned back, and the arms would sometimes require to be firmly held to keep her from throwing herself off the bed. She would come out of the attacks as suddenly as she went into them, usually with a sharp cry. Ordinarily the attacks did not seem to exhaust her to any important degree, except when very frequently repeated. Immediately on coming out of an attack her head was as clear as usual, and she would go on with conversation that had been interrupted, as though nothing had happened. The excessively irritable state of the middle dorsal vertebrae evidently had some relation to the convulsions, and the query whether the pathological condition of the cord at that point was anything more than exhaustion was at once raised. After long study of the case, I became convinced that the pathology of the cord in this sensitive region was irritation dependent on exhaustion or myelasthenia, and not inflammation or congestion either of the cord or of its membranes. The ovaries were quite sensitive to pressure on both sides, as usual in all such cases. I believe that the pathology of the cord and of the ovaries was essentially the same. The whole spine, I should say, was more or less irritable, and there was persistent aching of the lower limbs, especially of the ankles. There was no proof of uterine trouble, or

\*The delusion that fish is especially adapted to feed the brain, and that fish-eaters are therefore more intellectual than the average, is so early opposed to chemistry, physiology, and to history, to common observation, that it is very naturally almost universally accepted by the American people.

The delusion was started by the late Prof. Agassiz, who, impulsively and without previous consideration apparently, as was his wont at times, made a statement to that effect before a committee on fisheries of the Massachusetts Legislature. The statement was so novel, so decided, and so untrue, that it spread like the blue-glass delusion, and became the accepted creed of the nation.

any reason to suspect it. The appetite was tolerably good, and the bowels and vessels tolerably regular. The pupils were dilated, and there was much headache.

The patient was a school-girl, and apparently had been brought into this state through over-confinement, but there may have been other exciting causes of which I know nothing. The case was one of hysterio-epilepsy, as described by Charcot—a combination of hysteria, and the symptoms of loss of consciousness during the attack is supposed to be diagnostic of epilepsy. There was no frothing at the mouth, and no stupor after the attacks, which, by the way, were far too frequent for pure epilepsy. The case throughout suggested hysteria far more than epilepsy.

The treatment at first used was spinal and central galvanization with very mild, non-perceptible currents and short applications, and in connection with the electricity, bags of ice and hot water to the irritable region of the spine, and counter-irritation by means of very small blisters. Very mild general faradization was tried once or twice, but did not seem to work well.

Bromide of potassium and sodium were also given to produce sleep and allay irritability; they had been used, however, for a long time before electrical treatment was begun, without producing important results.

After the patient had been treated by these methods three months, the improvement was so slight that I began to be discouraged; but the friends were confident that benefit had been received, and desired to persevere. I now returned to general faradization, which, when tried before, had not worked well. From that time the improvement was of a positive, cheering character, although there were frequent relapses. Bromide of camphor was used to a certain extent, and with apparently good effects. Calabar bean was tried and abandoned. For the frequent and severe headache, caffeine worked admirably. I have already called attention to the value of caffeine in sick headache, and have given suggestions in regard to the manner of using it. The remedy I find to be useful in other forms of headache besides sick headache. In this particular case there was the feeling as of a band around the head, and great pain at times. Of the different forms of caffeine I prefer the citrate, since it seems to accomplish the desired results with a smaller dose, and more surely. I have not yet made up my mind in regard to the exact dose in which caffeine should be given, having been accustomed to pour it out in the hand, rather than to weigh it out. My present custom is to prescribe it in two-grain powders, with directions to repeat every half-hour until the headache disappears. The failures with caffeine are, I am persuaded, often due to timidity in the use of it. It is a powerful, but, in reasonable doses, not dangerous remedy. One case has been brought to my attention—the wife of a physician—where there was an idiosyncrasy that could not endure caffeine; but, as a rule, the only unpleasant effect it produces is wakefulness, and that is only observed when the remedy is given late in the day. When this remedy is given in a dose just adapted to the needs of the sufferer, it quickly and perfectly removes the pain in the head and the nausea. I have known it to produce this effect in less than fifteen minutes, even after the patient had been suffering a long time.

The use of caffeine in headache seems to me to be one of the most important of the special therapeutic advances of our time; it is a genuine and solid reality, the relief it produces being too speedy and too frequent to be accounted for by coincidence or mental

influence. It deserves to rank just after chloral, bromide of potassium, hypodermic injections, and electricity. Its superiority to guarana is very decided. Caffeine, it will be remembered, is the active principle common to coffee, tea, chocolate, and guarana, and is preferable to the latter in the treatment of headache, not because it is more sure and speedy, but also because it is more convenient and agreeable, and is never refused by the stomach. Guarana must often be given in bulk, and withal, is not a little nauseating both in taste and odor. Sometimes patients throw it up at once. Various other modes of treatment of headache—such as electricity and carbonic acid, must be practically useless for the majority of cases, since they cannot be brought to bear when needed—that is, at the outset of or during an attack. It is better to give the citrate of caffeine just as the headache is coming on, but it may be given with success at almost any stage, and when the proper dose is taken it seems to take up pain and bear it away.

The relief derived from caffeine was so marked to the headache of the present case as to suggest the query whether the same remedy may not be used in other forms of pain besides headache, whether it may not be of service in the pain of spinal irritation (myelasthenia) and in general neuralgia and hay fever. Might it not be administered in small doses in inebriety, to sustain the nervous system after the habit of drinking is broken off?

In six months from the time treatment was begun the patient was at least half well, and in less than a year her recovery was practically complete. Throughout the year much tact and judgment were required in regard to her exercise. Slight over-exertion would often cause a relapse. It was long before she could stand or walk a step without bringing on convulsions; and when she was able to walk across the floor, it was felt that a great triumph had been achieved. The advice I constantly gave was to underdo rather than overdo; to stop short always of fatigue; but to increase her walking distance each week or day by a few steps if possible. In the latter half of the treatment, the influence of special, definite, and limited expectation was utilized with very important results. The patient was having a number of attacks every week; she was told to make up her mind and to concentrate her efforts in the attempt to reduce the number of attacks to four weekly. To this suggestion she heartily acceded, and was rewarded by more rapid improvement than she had experienced at any previous time. Although she rarely attained her ideal in any week, she sometimes closely approximated it.

The treatment was so complex that it is impossible as it is unnecessary to assign to each of the various remedies used its own proper and peculiar share; but as far as I could judge from the immediate effects general faradization, central and local galvanization, ice and hot-water bags, counter-irritation, or special expectation, were the leading curative agents.

This case illustrates what can be accomplished under apparently hopeless circumstances by a persistent and simultaneous use of our best recognized sedative—tonics.

In some cases faradization is borne better than galvanization, as in the following:

## II. HYSTERICAL CONVULSIONS — HALLUCINATIONS — HYPER-ÆSTHESIA—RECOVERY.

Mrs. —, aged twenty-six, I first saw in July, 1877. Two years before she had been hit in the back by carriage pole while crossing Broadway, and had su-

ferred more or less ever since from nervous symptoms. Hysterical convulsions came on at irregular intervals, and under various exciting causes. These convulsions were sometimes preceded by an aura, or indefinable sensation starting from the region of the clitoris. There had been over-use of the sexual organs, and the uterus was much engorged. This engorgement had been faithfully treated by her physician, but the ordinary remedies, local or general, were not well borne.

Even when there were no attacks of convulsions, there was excessive neurasthenia, with all the usual symptoms, all of which were much worse at the monthly periods. She was subject at times to various hallucinations; she would see spectres and all sorts and forms of living things, and hold sustained converse with subjective human beings. At one of my earlier visits, she observed, as I was leaving the room, "I see a man standing between you and me. I see him as plainly as I see you." On another occasion she remarked, that her arm seemed to be covered all over with insects. Illusions of hearing were not uncommon; she once distinctly heard a voice commanding her to get out of bed. During one attack of nervous depression, she described her sensations to have been like "acres of fire rolling up and down the spinal cord."

I began treatment with mild general faradization, then tried central and local galvanization, and as these methods did not seem to work well, returned to general faradization, which was kept up until she substantially recovered. In connection with general faradization, local faradization of the uterus was used, and both methods answered each their purpose. The patient improved in a most satisfactory way, despite certain mental difficulties that caused occasional relapses. Although so sensitive to many other remedies, she bore faradization in large doses, and with only good effects. The improvement continued long after the treatment was discontinued; and now for eighteen months she has been in perfect good health.

In the above case the psychology of the patient was on my side; she was naturally hopeful, cheerful, and was resolved to get well. The hygiene of the patient was managed by her physician with great skill and judgment. She was never allowed to overdo, but was cautioned always to husband her strength, and to exercise only within proper limits.

The disposition to relapse observed in both of the above detailed cases, is a characteristic feature of the family of diseases to which it belongs. It is a feature common to these ten diseases—hay fever, inebriety, spinal irritation, nervous dyspepsia, neurasthenia, physical hysteria, and general neuralgia, cerebral irritation, pathophobia, and sick headache. These relapses do not usually prevent ultimate recovery, and should not dishearten either physicians or sufferers.

The following case would formerly have been regarded as hypochondriasis, and the patient would have been described as simply "hyped." The majority of physicians even now employ that diagnosis. It represents a peculiar phase of morbid fear.

### III.—AGORAPHOBIA (FEAR OF PLACES) OF LONG STANDING AND PECULIAR SYMPTOMS.

A gentleman under middle life had for very many years been annoyed by a morbid fear of going across squares, or at any considerable distance from stores or shops. He must have some place of ready refuge near at hand, where, if the need should arise, he could flee at once. To be in the neighborhood of dwelling-houses gives no sense of protection, because it would be impossible to enter them without the delay of ring-

ing the bell and waiting for the servant to open the door. Stores and open shops can be entered instantly; however, he feels secure when riding up Broadway, but very insecure when riding up Fifth Avenue. He never has occasion to take refuge in any shop or store or residence; he does not faint, as he apprehends he may, nor does he ever actually experience the need of any assistance; it is merely the consciousness that a refuge is near that he requires. At one time, when riding in a stage that left Broadway at Twenty-third Street, and went up on the right side of Madison Square, his alarm was so great that he cried aloud for a moment. Sometimes he finds that he is wandering too far from stores, and must turn round and run back as if for his life. He cannot visit the country, or even ride through Central Park; but is perforce shut up in the city, and is restricted to those portions that are devoted to business. To cross from one avenue to another through a side street is about as much as he dare attempt.

Yet another and still more unusual peculiarity of this case is, that wherever he goes he must take with him a number of bottles of strong or malt liquors. He has found by trial, when the feeling of alarm comes upon him, he can be relieved by drinking ale or porter, or gin in moderate quantities; consequently he carries samples of these liquors with him wherever he goes, every day and on all occasions, and is never happy unless he knows that the bag containing these comforters is at hand. He does not drink those liquors as he walks or rides about, any more than he enters the shops; it is the sense of security that he wishes—the consciousness that he can have them if he should need them. This gentleman attributes the origin of his unprecedented and incredible phase of agoraphobia to excessive tea-drinking for about twenty years. Since that time he has been off and on engaged in speculation, and so may have increased this special susceptibility. In most other respects his health is fair, although he is subject to cerebral hyperemia, and has attacks of nervous dyspepsia.

The man who soberly details these symptoms is of more than average intelligence and culture, and analyzes his symptoms as coolly as though they belonged to another party, and moreover, is amused as well as annoyed by their peculiarities and perversities.

To call all this imagination is to beg the issue. In pathology, strictly speaking, nothing is imaginary. When we use the term imaginary in relation to disease, we mean subjective as distinguished from objective; but the former are as much realistic as the latter. A man who induces or maintains a state of disease through an excess of self-absorption by turning his mind upon himself through the emotions of fear and expectation, may be just as truly diseased as though he were knocked down with an axe.

Equally mistaken is the reasoning which assumes that sufferers of this kind can be cured through their own wills alone, and that the fact that they are so cured is proof of the imaginary nature of their malady. Functional diseases of all kinds may be permanently cured, and structural diseases may oftentimes be relieved through subjective or mental treatment; but such cures are no proof of the unreal nature of the diseases that are cured, for subjective treatment is as truly a fact as objective treatment, and works by law like the objective treatment of drugs and hygiene, and is oftentimes more effective, not only transiently, but permanently.

A man standing on the foot-bridge between the Brooklyn and New York towers and experiencing a sense of sinking in, of dizziness, or of utter despair,

as many do when standing on heights, is in a condition analogous to that of the patient whose case I am here describing; he is in a pathological state, induced subjectively through fear of falling, but it is a reality just as though it were induced by the actual shock of a fall. There are many who dread the very thought of going up a height, just as my patient dreaded to leave the vicinity of shops and stores. If a person thus sensitive in this special direction could be deceived successfully, if he could be led into walking across the foot-bridge under the delusion that he was walking on solid earth, he would not be troubled; it is the consciousness that he is on a height that causes him to grow dizzy and faint and despairing, and not the position itself, just as in the case of my patient it is the consciousness of being away from shops or alcohol that causes a feeling of alarm.

All cases of this kind illustrate the practical unity of mind and body. Inability to go up a height is the result of mental organization—a deficiency, no doubt, of certain mental qualities; but nervous debility, however induced, always aggravates this state. A man who can go up a height without difficulty when he is well, may find it beyond his power to do so when he is enfeebled by chronic nervous disease, although his muscular power is unaffected.

Likewise in agoraphobia, or fear of places, and in astrophobia, or fear of lightning, as I have elsewhere described it, the symptoms are the coupled results of mental organization and nervous susceptibility, either inherited or acquired. The treatment should therefore be both subjective and objective—sedatives and tonics, and nerve-food, rest and liberal nourishment, competing with mental discipline and diversion. To say to such patients, "Exercise your will-power, and you will be cured," is like saying to a small-pox sufferer, "Remove some pustules and drive out the fever and the fever-poison, and you are all right," or, in other words, "When you are well you are well."

The case under discussion has never taken treatment to any great extent, and has never been benefited by the little that he has tried. The malady is of so long standing that it seems to be a fixed fact, and yet it would probably yield if the patient could be persuaded to take the proper course and to persevere in it—if, for example, he would take tonic and sedative treatment, and would gradually discipline himself to take walks every day farther and farther away from shop and store, he might recover; in other words, if the patient was only somebody else, he would get well; but if he had been somebody else, he would not have been sick.

That morbid fear of places depends on nervous exhaustion, and may disappear, is shown by the history of the following case now under my observation:

NEURASTHENIA FROM SELF-ABUSE—TEMPORARY AGORAPHOBIA—NERVOUS FEVER AND PROFOUND SENSE OF EXHAUSTION—IMPROVEMENT.

A young man aged 24, has been a sufferer from severe nervous exhaustion for eight years. The evil habit to which his debility is attributed was begun at the early age of eleven years. When sixteen years old he was confined to his bed by what, from his description, appears to have been acute nervous exhaustion, with fever. There have been times when he has been oppressed with a sense of profound nervous exhaustion, as though he would sink through the earth. This sensation is not exactly pain, but it is really more painful than pain; it expresses a low state of the nervous system that is not strong enough for positive pain like neuralgia or headache. There has been dilatation of

the pupils, but no spinal irritation; some constipation, insomnia, and dyspepsia, but very little pathophobia, which is so common in such cases. Seminal emissions are at present not very frequent, and cause less than ordinary disturbance. Cases of this kind are too familiar to the literature of charlatanism, but altogether too much neglected in scientific literature.

In regard to these cases there are three important facts not always recognized.

*First.* It is not the simple act of self-abuse that makes the trouble, but the fact that it is begun early—before puberty oftentimes, as in the present case—and is repeated very frequently. In connection with this subject, Dr. Jacobi's excellent paper on masturbation in children is worthy of study.

*Secondly.* Individuals differ in their susceptibility to sexual abuse either in the natural or unnatural way, just as they may in their susceptibility to tobacco or alcohol. When, therefore, we are consulted by a case of nervous disease, and learn on inquiry that the patient has been indiscreet sexually, it is not always just or scientific to assume that these facts are in the relation of cause and effect. One man can smoke with impunity ten or twenty cigars daily; another man cannot take a whiff without suffering. A medical friend last year related me a case of a man in middle life, who for very many years had indulged several times daily in sexual intercourse or masturbation without any traceable injury, excepting perhaps a somewhat waxy look, which he might have had any way.

*Thirdly.* Sexual excess, when it injures, causes functional rather than structural trouble, and the effects, though quite severe, may disappear entirely. The notion that organic maladies, like locomotor ataxia, are caused by sexual excess, is quite wide of the truth. The law is that functional excess causes functional disease.

This young man was at one time troubled with fear of places, like the previous case, though less severely. He found it difficult to cross a square or to go far away from houses. At one time he was attacked on a ferry-boat, and found relief by leaving the cabin and going outside. I have known of three persons who for a time could not cross the ferry, their morbid fear taking this form; all of the cases recovered.

This young man had recovered of his fear of places before I saw him; the symptom disappeared as he grew stronger.

Under general faradization, central and spinal galvanization, combined with various sedatives and tonics, this patient has much improved and will no doubt substantially recover. His studies had been interrupted by his illness; he will now be able to resume them, or to go into business, as he may prefer. It is better that such patients be occupied; it is a mistake usually to take them away from their chosen pursuit, whatever it may be.

IV.—SPINAL IRRITATION—CAUSED BY OVER-PHYSICAL EXERTION—SPEEDY RECOVERY UNDER SPINAL GALVANIZATION.

A young lady, seventeen years of age, came under my care in the spring of 1876 with spinal irritation, induced by over-walking in shopping and sight-seeing trips with a friend. The patient was of fair, but not of firm health, was well without being strong, but was not anæmic. The tenderness was confined mostly to the middle lumbar vertebræ, but the middle dorsal to the shoulders were also somewhat affected. The accompanying pain in the back was easily made worse by walking about. There were no evidences of spinal congestion. It was the first attack of the kind

from which she had suffered, and she had been ill but a short time, and thus was unlike most of the cases, which are chronic and recurring.

Treatment by spinal galvanization gave relief at once, and after seven applications she was dismissed as cured. She has, I believe, remained well.

Spinal tenderness is a condition found in very many diseases—in spinal congestion, in meningitis, in spondylitis, in locomotor ataxia, and in progressive muscular atrophy. In ataxy and atrophy the spinal tenderness is found in the early stages usually, or at least in those portions of the cord where the degeneration is not complete, but in which the congested stage still exists. The existence of spinal tenderness is so far forth a good sign in these organic affections of the cord; the prognosis of those cases where it exists is better than of those cases where it does not exist. Spinal tenderness is not, however, diagnostic of the disease spinal irritation. *The diagnosis spinal irritation is only made where there is spinal tenderness; every symptom of inflammatory or structural disease of the cord, or of its membranes, or of the spinal column, is excluded.*

Next to headache, spinal irritation is the most common of diseases among American women. Thousands suffer from it all their lives off and on, without ever being directly treated for it. An attack may be brought on by over mental or physical exertion, by worry, by wakefulness, by excess, or by any exhausting influence; it may be reflected from the sexual organs, or from the stomach. Over-walking, as in the above case, is a very common cause. Long standing may excite the symptoms, but riding in carriages is an exciting cause of spinal and also of cerebral irritation far more frequently than is supposed.

Some persons in comparative health cannot ride at all, or but little, without suffering from headache or from ache in the back, or spinal irritation. I have under my observation four patients who are injured more by riding even in the easiest carriage than by any other form of motion. Two of them cannot ride a block without serious injury. Horse-cars are much easier than carriages, or even steam-cars; but one lady whom I have treated cannot ride any distance, even on the horse-cars, without aggravating her spinal irritation. In another case of neurasthenia both spinal and cerebral irritation are excited by a short ride, though not for several hours subsequently. Both cerebral and spinal irritation may be excited by the motion of riding.

Cerebral irritation is to the head what spinal irritation is to the spine. Its symptoms are tender points on the scalp, a sense of exhaustion, with inability to apply the mind for a long time, insomnia, and sharp, shooting pains through the head—or what is commonly called the "clavus hystericus." In spinal irritation there may be tender points the entire length of the spine, or only at certain points, and this general or local tenderness may disappear and reappear under treatment and exciting causes; just as in cerebral irritation, with which spinal irritation is often associated, there may be tenderness in nearly all parts of the scalp or only on the vertex, where there is sometimes a hot, burning feeling that is relieved by pressure.

In cerebral irritation the jar of walking sometimes makes the condition worse; even riding in the horse-cars is sometimes unendurable. Patients of this kind find great difficulty in being transported from place to place.

The quite popular impression that these diseases are caused mainly or entirely by sexual diseases, and particularly by diseases of the womb in women, is not correct. Sexual disease is one factor, and but one in their causation. All of these ten diseases, includ-

ing hysteria, are found in both sexes; some of the worst cases I have ever seen are males.

When created as the result of diseases of the womb, it is usually the less severe disease or displacement, and not from incurable conditions, as cancer, that produce the irritation. I have now under observation a case of very severe neurasthenia with cerebral and spinal irritation, that was excited fifteen years ago by a ruptured perineum, uterine engorgement and displacement—here followed an immense array of nervous symptoms.

Sunstroke and cerebro-spinal fever are likewise not uncommon causes; a few years since I published a number of cases in illustration.

That the sexual apparatus and its function have on the whole much to do with these diseases in both sexes, I am free to allow. A gentleman who has long been a sufferer from hay fever, and who has attacks, as many people do, at all seasons of the year, but especially in the summer, tells me that sexual intercourse is with him one of the most common of the exciting causes. I saw him in the midst of an attack which he said had been brought on in that way. That the sexual factor is a powerful one is suggested by the fact that in both sexes these diseases are most severe and distressing during the period of sexual activity, between fifteen and forty-five.

## Progress of Medical Science.

**PODOPHYLLIN IN THE TREATMENT OF HEPATIC COLIC.**—In a paper published a few months ago in *Lo Sperimentale*, Prof. Bufalini reported two cases of severe hepatic colic, that were cured by the use of small daily doses of podophyllin. The first case was that of a woman, 45 years of age, who had suffered for a long time from violent attacks of hepatic colic. Her only relief was obtained from the use of active purgatives, which would cause the discharge of large calculi. An enteritis finally set in, which compelled her to stop the use of purgatives. Prof. Bufalini then ordered small doses of podophyllin (gr. one-sixth per diem), and both the hepatic colic and the intestinal catarrh rapidly disappeared. The use of podophyllin was continued for a year, and during that time and the two years that have since elapsed, the colic did not return.

The second case was that of a lady who had suffered for over two years from violent attacks of hepatic colic, and frequently passed calculi. All the usual methods of treatment had been tried without benefit, but the use of one-sixth of a grain of podophyllin per diem was soon followed by a cessation of the attacks, and gall-stones were no longer passed. The use of podophyllin was after a time discontinued, and for eight months afterwards the health of the patient continued good; the attacks of colic then returned, and calculi were again found in the faces, but on resumption of the treatment they disappeared almost immediately.

To these cases Dr. Mercadé adds that of a lady, who suffered for a long time from intensely severe attacks of hepatic colic, that were repeated two or three times a month. He had been unable to do more than relieve her by injections of morphine. He finally ordered a small dose of podophyllin to be taken every night, and since the treatment was begun (two months ago) no attacks have been experienced. During the first fifteen days of this treatment the stools were examined, and several times were found to contain calculi. —*Gazette des Hôpitaux*, July 7th.

**ACUTE FATTY DEGENERATION IN INFANTS.**—In the *Archiv für Gynäkologie*, B. x., H. 3, Prof. Hecker relates a case of acute fatty degeneration in a new-born infant. The mother was 32 years old, unmarried, and pregnant for the sixth time. The child was a male, and breathed well, but its skin had a greenish discoloration, as if from decomposed liquor amnii. It died at the end of fourteen hours. At the autopsy the lungs were found expanded, but there were numerous subpleural extravasations, and the organs were filled in all directions with hemorrhagic infarctions. The pericardium presented ecchymoses, and the tissue of the heart was friable. The liver was of normal size, but of a deep yellow color, and its cells showed advanced infiltration with fatty molecules, which were found also in the heart and kidneys. The author considers this case confirmatory of the views of Buhl (*Klinik der Geburtskunde*, Vol. 1, 1861), who holds that acute fatty degeneration in children has very definite characters, somewhat analogous both to acute yellow atrophy of the liver and to the effects of phosphorus poisoning.

The author relates a second case somewhat analogous to the above. A female child was born at full time, on October 28, 1876, whose skin had a dirty yellowish tint, and was covered with petechiæ about the size of a pin's head, especially about the face, but well-marked also on the buttocks and lower extremities. The mother was a primipara, but the labor had been normal, the first stage lasting twenty hours, and the second one hour. The child died on the fourth day. At the autopsy, extensive extravasations were found between the muscles of the left side of the neck; there was considerable effusion of blood tearing up the cerebellum, and the whole spinal cord was surrounded with blood. The liver was of fair size, but tinged yellow. The heart and lungs showed numerous ecchymoses, and there were effusions of blood, without lesion of the mucous membrane, in the intestinal canal. On microscopic examination the liver, heart, and kidneys were found to have undergone a moderate degree of fatty degeneration. The spleen was enlarged. The proportion of white to red corpuscles in the blood was about one to six, hence there was a certain degree of leucæmia. Both the mother and father of the child appeared to be in perfect health. The author remarks that Gerhardt has stated that cases of leucæmia are not very uncommon in children, and have been observed even at the age of eight or ten weeks, but he believes that no congenital cases of the disease have hitherto been recorded.—*The Obstetrical Journal*, July, 1877.

**TREATMENT OF NASAL CATARRH.**—Dr. Hartmann, of Berlin, recommends the use of Politzer's method for distention of the middle ear, in the treatment of acute nasal catarrh. By the compression of the air in the nasal cavities, the collected secretion in the frontal sinuses and other cavities opening into the nasal fossæ is forced out, and the pains and other disagreeable sensations in the head are thereby greatly relieved. In order to prevent any undesirable effects on the middle ear, the external auditory canals should be closed with the fingers, whereby a too forcible driving outwards of the drums is prevented.

In non-syphilitic ozæna, Dr. Hartmann believes ulceration of the mucous membrane to be very rare, the bad smell being dependent on decomposition of retained secretion. He also believes that the great dilatation of the nasal cavity, which is very frequently found on one or both sides in cases of ozæna, renders the removal of the secretion difficult, and favors its

stagnation. Where douches or injections cannot be used, he recommends the use of a small brush, fastened at the end of a flexible wire, to remove the tenacious secretion.—*Memorabilien*, Heft 6, 1877.

**ANEURISM OF THE CAROTID CURED BY THE EXTERNAL APPLICATION OF ELECTRICITY.**—Prof. Pereira Guimaraez, of Rio Janeiro, reports this case. The tumor had existed about a year, and had grown very rapidly. It extended from below the clavicle to the upper border of the thyroid cartilage. Ice was kept constantly applied to the tumor for three weeks, but it did not produce the slightest effect. On October 20, 1874, the first application of electricity was made. The two electrodes of an electric machine were placed on the surface of the tumor, and moved about from place to place. The current was used as strong as the patient could bear it, and under its action the sternocleidomastoid contracted forcibly and painfully, thereby causing a diminution in the size of the tumor. The application was continued, with short intervals necessitated by the pain, for ten minutes. The sittings were repeated at intervals of two or three days. After the fourth, the tumor was noticed to be smaller, but there was some local inflammation, which, however, yielded in two days to the application of ice. After this two more electrical sittings were held, both of which were followed by inflammatory symptoms that readily yielded to the application of ice. The aneurism gradually became smaller, and its pulsations grew more and more feeble. On November 22d the tumor was reduced a third in size, and the patient was allowed to leave the hospital. He at once resumed his former avocation—that of a porter—and was soon able to carry even heavy loads on his head without inconvenience. In the beginning of 1876 the tumor was reduced to a hard, flattened, circular nodule, about as large as a penny.—*Gazette des Hôpitaux*, July 14th.

**ACUTE RHEUMATIC THYREOITIS.**—On June 7th a young man, who had been suffering for a long time from articular rheumatism, was admitted into the Charité, in Paris. The disease then affected chiefly the knees, hands, and shoulders. Auscultation revealed the existence of endocarditis. Two days after his admission, he was seized with high fever and violent headache, and complained of a painful sensation in the anterior region of the neck, which was increased by the movements of deglutition and of rotation of the head. During the following night the thyroid gland swelled, and attained such a size that, at the time of the visit of Prof. Vulpian on the next morning, the patient was scarcely able to swallow his saliva; he complained of very severe pain whenever the head was moved, or the front part of the neck pressed with the hand. An emetic was ordered, and on the following day the pain had entirely disappeared. The lateral lobes of the thyroid were still somewhat enlarged, but the redness, heat, and abnormal tenderness had all disappeared.—*Gazette des Hôpitaux*, June 25th.

**REMOVAL OF THE REMAINS OF MONTHYON.**—The mortal remains of Monthyon, the great philanthropist, which reposed under his statue in the peristyle of the old Hôtel-Dieu, in Paris, have been removed to the church of Saint-Julien-le-Pauvre, where they will remain until the monument in the new Hôtel-Dieu is completed. During his life Monthyon made many useful endowments, and at his death he left the bulk of his immense fortune to the hospitals of Paris.

# THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, September 15, 1877.

## THE FALL AND WINTER COLLEGE TERMS.

THE advent of the Fall season brings with it the usual activity in medical affairs. Societies resume their sessions, colleges commence their regular lecture terms, and the hospitals become once more peopled with students. To the young man who starts out to study medicine, the time is full of interest and fraught with anxiety. The choice of the proper medical school, of the proper preceptor, and the counting of the cost thereof, are matters which naturally engage his most serious attention. There are so many controlling circumstances which must naturally govern individual cases, that it would be impossible to lay down any absolute rules for guidance; still there are some general principles which should govern the course of every student, to which it may not be amiss at this time to refer.

We have so often referred to the necessity of preliminary education as one of the necessities in commencing the study of medicine, that it would be a culpable omission of a duty we owe alike to the profession and the student not to allude to it in this connection. Every sensible young man should know that his chances of success are ten to one in favor of a liberal education, and in the desperate struggle among first-class men already in the profession these chances are not to be lightly considered. But this point is now so well established that it has become an axiom, and is really beyond the necessity of argument.

There have been examples of poor young men who have become leaders in the profession, and who during their pupilage supported themselves by manual labor. This is very praiseworthy, but, as a rule, it is a very foolish proceeding, and should be discouraged. Any one who invests all his pecuniary capital in the mere study of medicine, with any hope of a decent return within a reasonable time, deserves commiseration from

the start. The fact that some succeed in spite of these obstacles is only a circumstance in favor of the individual rather than an argument in favor of a principle. But as each ambitious youngster believes himself an exception to any general rule of failure, we suppose that there will always be a certain proportion of this class in every school, and a certain proportion of melancholy failures in the end.

Scarcely second to these considerations are those which should govern the choice of a school. All other things being equal, the college which offers the greatest facilities is the best. The question is one of kind as well as of degree. As a rule, the institutions in large cities are the best. They command the best talent, are more subject to the purifying influences of "a generous rivalry," and are consequently anxious to tempt the student with extra advantages. Although this is the rule, there are not a few colleges in out of the way towns whose special qualities of teaching coax students from far and near to take advantage of them. But the scarcity of clinical dissection material is a great drawback, and the plentiful supply of both in metropolitan centres needs scarcely to be mentioned as inducements in favor of the latter.

Another point worthy of a passing reference is the chance of obtaining the best talent in the larger schools. So much depends upon the popularity of a professor with the students, that it is one of the elements which govern his appointment. No first-class medical college can afford to advertise any teacher who is unsuccessful or unpopular. Indeed, some of the larger schools have wisely adopted the plan of obtaining the best talent by inviting competition in lecturing to the students—the teacher who habitually draws the largest audience being sure in the end to secure a permanent appointment.

As all this is done for the benefit of the student and through him for the college, the chances are always in favor of the institutions that can command such competition and secure such teachers. But the best of schools avail nothing when neither sufficient time nor system is taken to pursue the requisite studies. This leads us to say a word in favor of all those institutions that allow ample time to pursue a properly graded course and provide for stated examinations as shall insure a compliance with these conditions.

The choice of a preceptor does not amount to a great deal one way or the other. At best he is usually but a figure-head who certifies to the time when his pupil commenced the so-called study of medicine, and also to the moral character of said pupil, both of which, especially the latter, are of the greatest importance in securing a diploma from the faculty. The office preceptor is in reality getting to be more and more of a myth, and his name upon the college catalogue or the certificate of time of study, etc., is a mere matter of form to cover the provisions of the college charter. As an instance of the truth of this, we call to

mind the fact that a leading medical college of this city accepted the certificate of a preceptor who lived in Colorado, while his pupil studied medicine in New York, and when at home resided in Syracuse. The progressive student of to-day does not need to be told that the so-called "quiz," either by specially trained examiners, or better still, by members of the faculty themselves, practically does away with the occasional dull recitals in a village office, while the hospital advantages of a large city no longer makes it necessary, for the mere sake of occasionally seeing a private patient with the "old doctor," to become office-boy and ostler for him during the greater part of the year.

#### SANITARY INSPECTION OF PUBLIC SCHOOLS.

THE Board of Health, in compliance with a resolution from the Board of Education, has made a sanitary inspection of the school-buildings of this city. As a result, sixteen of these have been found wanting in sanitary requirements, and have been referred back to the Educational Board for action. We cannot resist the conviction that this will probably be the end of the matter. It is well known that the Board of Education has been adverse to sanitary inspection in every form, and has during all the time the matter has been under discussion defiantly maintained that it was capable of looking after its own affairs, of which it claimed this sanitary inspection was one. This is past history; what the future will be is of course purely inferential, but we believe that there is very little chance for reform. The resolution asking for sanitary inspection was ostensibly a bid for public favor, and as an offset to the defeat of the sanitary school bill, which was thought to be a reasonable measure by every one else save those composing the Board of Education. The health bureau is merely asked for recommendations, and when these are made they can be accepted merely in the light of official courtesy and filed accordingly. Beyond this nothing can be done save by the pleasure of the Educational Board, as that body alone has the power to enforce any regulations either for the mental or physical well-being of the children. Judging the future by the past the outlook is discouraging. What is the use of making recommendations without the power of enforcing them?

#### ABUSES OF THE PROVIDENT SYSTEM.

THERE has been considerable complaint in Great Britain concerning the mismanagement of the provident dispensaries. As might have been expected, there are numerous fraudulent concerns of small capital, and less character, which pretend to minister to the wants of their patients for so much *per capita*. The fees are neither so large as the out-door department of the New York Hospital, nor is the stock as high, but the principle of management is the same; that is to say, any patient applies who chooses, pays his pittance, and re-

ceives medical advice. There is a slight difference, however, in that the physicians in these two-penny shops are the stockholders instead of a board of reputable trustees. Whether it is due to this fact or not, certain it is that many cases of neglect have come to light, some of which have been the subjects of inquiry before a coroner's jury. The question is whether there is not more or less danger of want of care in all cases where patients are crowded upon the attending physician, and where the average fee for each patient is so nominal as to be unworthy of consideration in connection with the amount of attention which any given individual may receive. Although such a state of things is to be deplored, it is one of the inevitable results of no pay or a poor pay system. That the latter imposes more obligations than the former, may be an argument in favor of provident concerns against ordinary dispensaries; but, judging from the experiences abroad, there is, at best, no very flattering hope of reaching a system that is either perfect or effective.

### THE MICROSCOPE IN THE DETECTION OF CRIME.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—The attention attracted to this subject, by recent controversies growing out of the application of the microscope in criminal trials, renders any information valuable that may tend to elucidate the several questions at issue. Until very recently it has been accepted as a positive fact of science that the red corpuscles in human blood are so much larger than they are in other animals that a specimen of the former could be identified by reference to their diameter alone. This opinion is still maintained by prominent microscopists, although not so decidedly as it once was. One of its most eminent advocates states his view as follows: "Although it would be scarcely proper to swear positively that a given stain on the clothing of a person on trial for murder is human blood, and not that of any other animal, yet, as between man and any specified animal, such as a hog, an ox, or a rabbit, an expert may swear with certainty." The point here is that a person indicted for murder usually accounts specifically for a stain by stating the circumstances under which it was acquired, and that if the stain can be sworn not to be from the particular animal to which it has been attributed, a jury is justified in the presumption that it is human blood. In this case, however, which is the most common aspect of the subject in trials for murder, it is evident that the uncertainty is still such as to admit of the existence of an honest doubt; for, although the explanation of the accused may have been completely disproved, the theory of the prosecution is not thereby demonstrated. In a word, the explanation of the prisoner that he has recently slaughtered a pig or a calf may be overturned by the statement of an expert that the stain on his clothing, or upon the knife or other instrument, could not have been produced in that way; and yet, unless the expert can positively state how it was produced, a necessary link in the evidence is still wanting. One case will illustrate the kind of evidence that the mi-

roscope has to offer in trials for murder. A woman in England was arrested for the murder of a little girl, and a blood-stained knife was produced by the prosecution, with which the deed was supposed to have been done. In the state of microscopic science at that date, the expert pronounced the stain to be human blood. This was probably uncertain; but when it was proved that the victim wore a tippet manufactured from a certain fur, and minute sections of the hair were identified, incorporated with a stain, the theory of the defence, which accounted for the blood by asserting that the murderess had recently used the knife to dress a rabbit, was not only broken down, but the counter-theory was fully demonstrated; for there is nothing in microscopic science which is more absolutely exact than the identification of hairs from different animals. Similar as rats and mice are, an expert would have no difficulty in determining to which animal a given section of a hair belonged. The evidence was thus full and positive in this instance; but had the conviction rested altogether upon the identification of the blood-corpuscles, the expert would not in the present state of the science have been justified in pronouncing positively.

The difficulty that lies in the way of doing so, independent of the fact that blood-corpuscles which have once been dried can never be accurately restored, consists in this: that there is no absolute standard of diameters that distinguishes red corpuscles of human blood from homologous bodies taken from the circulation of other mammalians. On the average the former are perhaps a trifle larger, but their diameter differs very materially in different persons in the first place, and in the second, the variation is very considerable in the same drop of blood. I have in my possession fifty-one slides of healthy blood, taken from persons of different temperaments, and fully illustrative of the extreme variations in diameter arising from this source alone. My observation has been that the red corpuscles are both larger and more numerous (as compared with the white ones) in healthy males than they are in healthy females; but, independent of this fact, the variation is very great in males of different temperaments. In glandular temperaments, for example, as contrasted with nerve temperaments, the red corpuscles are very considerably larger, less predominant in number, and transmit light less uniformly throughout the whole surface. In persons of dominant muscular structure they are again extraordinarily numerous as compared with other constituents of the blood; the apparent depression in the centre is more distinctly defined, and the cell-envelope appears to be appreciably thicker and rather less transparent. Paradoxical as the statement seems, in persons of predominant blood temperament I have never found the red corpuscles as large as in persons of glandular or muscular temperament. One slide among my specimens presents the best view I have ever had an opportunity to observe of the extreme variations in diameter that may occur in a single drop of blood. The smaller corpuscles in this specimen are 0.0035 millimetre in diameter, while some of the very largest are 0.0062—a range that is so very unusual as to be remarkable in its bearing on the important question under discussion. Two specimens in my possession, taken from the circulation of a monkey, present the following range: 0.0042 for the smallest, and 0.0065 for the largest. Taking a cabinet of slides, numbering in all seventy-two, and including specimens from the circulation of all the mammalia accessible in this climate, the average range is a little less perhaps than it would be in the same number of preparations of human blood, but not

nearly ten per cent. less, so that on the whole I am bound to say that the difference in the diameter of the red corpuscles (taking a specimen preparation from the blood of a highly nervous person as one extreme, and a specimen slide of the glandular temperament as the other extreme), is greater in different specimens of human blood than it appears to be in comparing average specimens of human blood with specimens obtained from the inferior animals. Of course, all these peculiarities of behavior in the fresh state, that enable experts to determine with a high degree of certainty between specimens of fresh blood and to assign to each its proper origin, are conspicuously absent in most murder cases; the dried and shrunken corpuscles have to be specially treated in order to free them from accidental products, and to disengage them from the fabric or instrument, and the result is that neither their living diameter nor their original appearance can be ascertained with any such precision as to justify an expert in stating unqualifiedly that they are from human blood. I have in my possession seven slides, in the preparation of which I permitted blood-stains on linen, from seven different animals, to dry for three days; then cut small sections of the linen with the corpuscles still adherent, and mounted them in self-hardening balsam. The dog, the cat, the hog, the cow, the mouse, and the sheep are represented by six of the slides. The seventh is blood taken from my own finger. The balsam has of course rendered the linen fabric quite transparent, and the stains can be studied in detail under more favorable conditions than ordinarily occur in such cases. But even in this instance, if the seven slides had not been properly labelled at the date of their preparation, I should scarcely feel at liberty to pronounce upon them with such absolute certainty as would be required to satisfy a jury. In a similar manner, although it has long been held by German experts that the red coloring matter of the blood differs so uniformly in its crystalline structure in different animals as to enable the microscopist to identify human blood by this test alone, it has been found on later investigation that the crystalline elements of animal blood behave very differently under different conditions; so that this once implicitly-accepted criterion is as unreliable as the rest. Taken in conjunction with other forms of evidence, the judgment of an expert as to the origin of a blood-stain is no doubt often valuable; but it should be well understood by juries that there is nothing infallible about it, and that no man particularly familiar with all the sources of fallacy incident to such investigations would suffer a life to be staked on the accuracy of his opinion. The same remark applies to the testimony of the spectroscope under similar circumstances, although the latter is particularly delicate in detecting minute traces of mineral poisons when incorporated with animal tissues. Indeed, in examinations of blood, urine, and perspiration, and in the general work of diagnosing, I have often found the common pocket spectroscope a better detective of morbid tissue changes than my best two-millimetre glasses. The moral is obvious that in cases of poisoning the spectroscope will ultimately become our best and surest aid to correct diagnosis. In using Towles's solution of arsenic for intermittent fever on my own person, the spectroscope showed arsenic in specimens of urine within an hour after administration of the drug.

In the detection of adulterations in articles of diet, the microscope is very efficient. It is better adapted, however, to the discovery and description of diseased products, such as milk from diseased cows, than to the

detection of admixtures, although the addition of a small percentage of water to healthy milk produces identifiable changes in milk corpuscles. In the detection of forgeries, again, the great powers of the instrument may be employed to great advantage. An imitated signature, for instance, although executed with ink of the same color as the original, usually shows a hesitating and somewhat jagged and irregular edge or margin of the strokes, due probably to the fact that the hand of the forger has to be consciously and carefully guided, the stroke consisting of a series of muscular impulses, in place of being the product of a single impulse. An artist acquaintance of mine executes at sight, with extraordinary rapidity, imitations of signatures; but, although the unarmed eye could not possibly detect the slightest hesitancy of the stroke, the forgery can be instantly detected by comparing the margin of an imitated letter with that of the same letter from a genuine signature.

FRANCIS GERRY FAIRFIELD.

### CONTRACT PRACTICE.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—Though the meaning of the more important doubtful points in our "Code of Ethics" has been authoritatively explained, yet portions of the law continue to be violated. It will be remembered that in 1873 the "American Medical Association" assigned its judicial committee the task of a general revision of the "Code." The chairman of said committee, "being desirous of ascertaining how far there existed a desire in the minds of the profession to have the code changed, addressed letters of inquiry to thirty or forty men in different parts of the country who might be supposed to represent the general sentiment of the profession in their respective districts, from twenty-five of whom answers were received." Fourteen expressed entire approval of the code, six opposed any general revision, but suggested slight changes, while only five desired thorough revision. Allow me to now quote those portions of the committee's report which apply to the subject of this communication.

"To govern the matter of compensation, the code simply gives us the following general declaration: 'Some general rules should be adopted by the faculty, in every town or district, relative to pecuniary acknowledgments from their patients; and it should be deemed a point of honor to adhere to these rules with as much uniformity as varying circumstances will admit.' The aim appears to have been to allow sufficient variations in the rate of compensation to accommodate the varying habits and circumstances of different communities, and yet to bind each individual to an honorable compliance with the general rules established by his professional brethren. Such being the correct ethical principle, the difficulty consists in tracing and maintaining clearly its practical application. That the principle laid down in the paragraph just quoted is inconsistent with all contracts or agreements to attend individuals, families, companies, corporations, or any associations or institutions other than those of a strictly charitable character, for a specified sum per month or year, without regard to the amount of medical services that might be required in the time specified, no one can reasonably doubt. It seems to us equally inconsistent with the ethical rule to enter into a contract with a manufacturing company to attend their employes, or with a school to attend its patrons or scholars, for a fixed sum per annum, to be derived from the levy of a certain percentage on the wages of

the employes, or on the tuition fees of the students; for, however plausible may be the humanitarian idea of securing for the employe and the student adequate medical attendance when sick, at the smallest average cost, the practical working of the system violates both the rule that compensation for medical services should be in accordance with the kind and amount of services rendered, and that every individual and family should be free to choose their own medical attendant without dictation or indirect restraint.

"These observations do not apply to a certain kind of contract service sometimes required in connection with the medical staffs of the army and navy, nor to the hospital tax on sailors in the marine hospital system, for reasons too obvious to require mention.

"One other subject requires a few moments' attention. There is a class of public charitable institutions, such as county almshouses, orphan asylums, etc., supported by public taxation. In many of the States the public authorities having control of such institutions have annually asked for bids from the profession, offering to award the contract for professional services to the one who should bid for the lowest pecuniary consideration.

"While as charitable institutions any member of the profession might offer his services to such of the poor inmates as might ask for them gratuitously, yet the idea of asking members of the profession to bid against each other for the pay for public professional services, is repugnant to every feeling of professional honor, and often productive of great injustice to the sick poor.

"The public authorities in all such cases should fix such just rate of compensation for the necessary medical services as they may deem best, and then appoint the best medical man who is willing to accept the compensation proposed. And we have no doubt but that a proper attention to this subject on the part of the profession would secure the necessary change.

"It is, however, very desirable to so manage all our pecuniary relations with the public, and especially with municipal and legislative authorities, that we avoid creating the impression on the public mind that the profession and its social organizations are little better than mere trades-unions, having for their chief object mutual pecuniary protection. After carefully reviewing the whole subject, your committee do not recommend any alteration in the present code of ethics. On the contrary, we desire to express the opinion that if every medical school and society would supply each graduate as he left the school, and each member initiated into the society, with a printed copy of the code, accompanied with the injunction that it be carefully studied, it would be productive of much good, directly to the profession and indirectly to the community."

It is to be greatly regretted that, after such decision on the part of an authoritative committee, many physicians still exceed the law in regard to contract doctoring.

It is no rare occurrence for an incorporated business company to approach the physician with a list of its employes, accompanied by an offer of a certain periodic sum, in consideration of which all needful professional services, medicine, etc., are to be furnished said employes without any extra charge whatsoever.

By this arrangement, those employes who avail themselves of the benefit, consent to the deduction from their wages of a certain sum per week, month, or quarter, which amounts in aggregate are paid the doctor at stated intervals.

Married men may, in addition, include the attend-

ance upon their families by payment of a larger levy. In some instances obstetrical work and fractures are charged for extra.

Sometimes the physician himself makes the advance by approaching the manager of the company with specifications of the amount and character of professional service which may be obtained for a given sum per time stated.

Unfortunately this violation of the code—for such we must at present regard it—is not only indulged in by those whom we might suppose to be less conversant with its meaning, but also by many physicians who are active and honored members of regularly organized medical societies.

Indeed, the name of a highly esteemed and distinguished practitioner has been authoritatively mentioned in close connection with contract practice.

About two years ago the manager of a company employing a large number of workmen expressed himself as most desirous of having all medical attendance upon the employés and their families rendered by one or two physicians, in consideration of a certain sum per month. Having always regarded the bestowal of medical services by contract as unprofessional and degrading in its tendency, and knowing the action of the "American Medical Association" upon the subject, I discouraged the gentleman from resorting to the arrangement. I am confident that he has not since attempted to adopt such a plan.

Had I then been asked if physicians in good standing engaged in such service, I should have unhesitatingly replied in the negative, for at that time I thoroughly believed the bestowal of all contract service to be generally regarded as incompatible with the code.

If we may overlook the decision of the Judicial Committee, and the unanimous approval of said decision by the "American Medical Association," I can readily understand how a physician might bestow service by contract and yet not violate the *literal* meaning of the code. There are communities, *i. e.*, certain mining and manufacturing districts, where physicians receive but meagre compensation except by recourse to such means, and where the circumstances would perhaps excuse a departure from accepted methods.

If that part of the code relating to pecuniary acknowledgments does not forbid contract doctoring, then it is certainly the duty of every regular medical society within whose jurisdiction such practices occur, to see that they be conducted in a manner which shall not compromise the dignity and honor of the profession.

If, in certain localities, the profession find that only by contract they can secure compensation for services rendered employés of incorporated companies, why not bring the matter openly before its local medical society and decide upon a plan to adopt. Should said society sanction contract practice, let it also fix a certain sum per capita as a minimum price for the service. This valuation should be sufficiently large to secure the best talent in the community. This would put the question of cheapness in a minor light, and thereby relieve the so-called irregular practice of its most formidable objection.

P. A. HARRIS.

DOVER, N. J.

DR. DUBLANCHET, formerly house-surgeon in one of her hospitals in Paris, died recently of diphtheria, after less than forty-eight hours' illness. The disease was contracted while attending to a child that was suffering from croup.

ARMY NEWS.

*Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from Sept. 2, to Sept. 8, 1877.*

NORRIS, B., Major and Surgeon. Granted leave of absence for one month. S. O. 186, A. G. O., Sept. 1, 1877.

McCLELLAN, E., Major and Surgeon. Relieved from duty in Dept. of the South, and to report in person, without delay, to the Comd'g General Dept. of the Columbia, for assignment to duty. S. O. 185, A. G. O., Aug. 31, 1877.

GREENLEAF, C. R., Major and Surgeon. Relieved from duty in Dept. of the Gulf, and to report to the Comd'g General Div. of the Atlantic, for instructions with view to accompany the 3d Infy to the West. S. O. 188, A. G. O., Sept. 4, 1877.

SMART, CHAS., Capt. and Asst. Surgeon. To proceed at once from Camp Douglas, U. T., to Camp Brown, Wy. T., and report to Col. Merritt, 5th Cav., for field service. S. O. 109, Dept. of the Platte, Aug. 31, 1877.

KINSMAN, J. H., Capt. and Asst. Surgeon. Relieved from duty in Dept. of the Gulf, and on expiration of his present leave of absence, to report in person to the Comd'g General Div. of the Atlantic, for duty. S. O. 188, C. S., A. G. O.

DEWITT, C., Capt. and Asst. Surgeon. Assigned to temporary duty at Fort Fred. Steele, Wy. T. S. O. 107, Dept. of the Platte, Aug. 28, 1877.

DEHANNE, J. V., Capt. and Asst. Surgeon. Assigned to duty as Post Surgeon at Fort Concho, Texas. S. O. 153, Dept. of Texas, Aug. 27, 1877.

KING, J. H. T., Capt. and Asst. Surgeon. When relieved by Asst. Surgeon De Hanne, to proceed to Fort Concho, Texas, and report to the Comd'g officer for duty as Post Surgeon. S. O. 153, C. S., Dept. of Texas.

ROBINSON, S. Q., 1st Lieut. and Asst. Surgeon. Relieved from duty in the Dept. of West Point, and to accompany the 3d Inf. to the West. S. O. 186, A. G. O., Sept. 1, 1877.

DAVIS, WM. B., 1st Lieut. and Asst. Surgeon. Relieved from duty at St. Louis Barracks, Mo., and to report in person to Comd'g General Dept. of Dakota for assignment. S. O. 185, C. S., A. G. O.

THE LATE PROF. A. B. CROSBY.—Those who were not intimately acquainted with the late Prof. Crosby were astonished at the apparent suddenness of his

death. In the absence of more positive statements, the theory of apoplexy was accepted as most probable, and one which would reconcile itself to his robust appearance, florid complexion, and vivacious manner. It now appears that he had been suffering from Bright's disease for some time past, and that he was doubtless acquainted with his condition and foresaw the ultimate issue. We learn from Dr. Frost, who was his attending physician, and a part of whose letter appears in the Proceedings of the Medical Society of the County of Kings, that "Dr. Crosby was not known to be ill till August 1st by anybody but himself, and he only knew for four days before that he was unusually thirsty and probably felt languid. On August 1st, while listening to Dr. Peaslee's Introductory Lecture, he said that all the black-haired men on the back seats had spectacles on, and he also noticed trouble with vision for all objects a little beyond ordinary focal distance. The thirst increased so that as he lectured he was obliged to wet his mouth constantly. The urine was much increased in quantity—specific gravity, 1033; sugar, ten per cent.—Monday, 6th, he took a swim in the river; also Tuesday—an injudicious proceeding. Wednesday, 8th, he kept the house. Wednesday night symptoms not much changed. He passed urine at 8 P.M., again at 4 A.M. Thursday, but in small quantity, and again at 8 A.M. Soon after he grew comatose, and at nine, when I saw him, he could not be roused, and swallowed only till a little after ten, and died at one P.M. The lesion *distinctly* found on autopsy was with the kidneys. One of these I sent to Prof. H. R. Pitz, of Harvard College, and he reports kidney extensively diseased, scarcely a normal tubule present.

With the microscope an excessive fatty and granular degeneration of the tubular epithelium. Parenchymatous nephritis was evident, etc., etc." Dr. Crosby delivered, in 1873, an oration before the Kings County Society on "The Significance of Pain."

**FAMINE IN INDIA.**—The editor of the *Madras Times*, who is a member of the Relief Committee, writes under date of August 1, as follows: "The population in Southern India more or less afflicted by famine numbers 24,000,000. In the most favorable circumstances at least one-sixth of the people will die. The famine is immeasurably greater than was that in Bengal. Twenty-three people, in all, died of starvation in Bengal. In Madras, no camp of 3,000 rises morning after morning without leaving thirty corpses. In the interior the distress is most fearful. One gentleman passing down a valley in the Wynnad district, counted twenty-nine dead bodies on the road. A coffee-planter, seeking shelter from the rain in a hut, found six decomposing corpses in it. On any day, and every day, mothers may be seen in the streets of Madras offering their children for sale, while the foundling portion of the poor-house is full of infants found by the police on the roads, deserted by their parents. Since the famine commenced 500,000 people have died of want and distress. The first big tragedy may be expected in Mysore. In that province, indeed, information has reached me from Bangalore of two cases of cannibalism already.

**NEW TEST FOR WINE.**—Under the name of "Oenokrine," a new test-paper, which, it is stated, will at once detect the presence of any artificial coloring matter in wine, has recently been introduced into notice in Paris. When the paper is dipped into pure red wine, it is immediately colored grayish blue, and becomes lead-colored on drying. On the other hand, when moistened with wine that has been artificially colored by fuchsine or other aniline substances, the

test-paper assumes a bright carmine-red color; when the wine has been colored by ammoniacal cochineal, the paper becomes pale violet; when by elderberries or mallow flowers, bright green; when by logwood, the color of the husks of pressed grapes; when by Brazil-wood or scarlet grains, dirty yellow; when by indigo-extract, deep blue. The method of testing is very simple: a strip of oenokrine paper is left for about five seconds in pure wine, and is then well shaken to remove the excess of fluid, and laid upon a sheet of white paper, which brings out the color more sharply. A second strip of the test-paper is then moistened in the suspected wine, and laid along side the first, when any difference in the color of the two will at once become apparent. It is positively stated that even one hundred-thousandth of a part of fuchsine in the wine is sufficient to give the paper a light violet color, while a larger quantity brings out a bright carmine-red. Lainville and Roy, the discoverers of "oenokrine," assert that they have also discovered a method by which the fuchsine can be removed from the wine without injuring the latter.

**PHOTOGRAPHS OF BACTERIA.**—The photographs of bacteria, which were prepared by Dr. Koch, of Wollstein, already famous from his investigations on anthrax, and sent by him to Professor Ferd. Cohn, have created a sensation in medical circles in Breslau. Dr. Koch has, after patient study, discovered a method of taking photographs, which not only confirm previous observations on these important organisms, but, as the photographic plate is more sensitive than the retina of the eye, also render manifest some hitherto unknown peculiarities. The photographs so far exhibited show specimens of bacteria, bacilla, and spirilla, and of many hitherto unknown varieties of spores.

**THE PLAGUE.**—In consequence of the extension of the plague to Bagdad and in Mesopotamia, the Civil Governor of Algeria recently gave notice to the Mohammedans in his jurisdiction, that no more pilgrimages to Mecca will be allowed for the present. The interdict is not permanent, but will be raised as soon as circumstances will permit. ]

**ANTHRAX MALIGNUS IN NEW CALEDONIA.**—We learn from *Le Temps* that an epidemic of carbuncular fever has broken out in New Caledonia, particularly in the Isle of Pines, and has caused great ravages among the inhabitants, as well as among animals. The flies appear to be the most active agents in spreading the contagion. The epidemic is on the increase; at the date of the report the number of victims was already above sixty.

**POLYGAMY AMONG SAVAGES.**—A writer in the *Revue Scientifique* asserts that the universality of polygamy among savages may be accounted for by one evident, though it is perhaps not the only cause. With us, after infants have been weaned, milk remains for a long time an important and essential article of their food, and for this purpose we use cows' milk, etc. Tribes, however, which do not possess domestic animals, have no substitute for the mother's milk, and hence the children are not weaned until they are two, three, or even four years old. Now, as man and wife usually remain separate during the period of lactation, it follows that, unless the man have several wives, he will be practically a bachelor for a large portion of his married life. In Viti the parents of a woman regard the birth of a second child before three or four years have elapsed, as a public insult, which they feel called upon to avenge in a public manner.

## Original Lectures.

## LECTURES ON DISEASES OF THE HEART.

By AUSTIN FLINT, M.D.,

PROFESSOR OF THE PRINCIPLES AND PRACTICE OF MEDICINE AND OF CLINICAL MEDICINE, IN THE BELLEVUE HOSPITAL MEDICAL COLLEGE.

[Reported for THE MEDICAL RECORD.]

## LECTURE III.

## ENLARGEMENT OF THE HEART (CONTINUED)—TREATMENT OF VALVULAR LESIONS.

GENTLEMEN:—At the close of the last lecture we were considering the subject of enlargement of the heart, and the means by which its presence is ascertained. I gave you the rules for determining the boundaries of the superficial cardiac space, and also the boundaries of the heart itself. I also spoke of the direction in which you were particularly to look for enlargement, namely, downward and to the left, and spoke of the means by which you would be able to determine the degrees and kind of enlargement. The fact of enlargement and the degree is determined, as you may recollect, first by finding the apex-beat wherever it may be. Its normal position is in the fifth intercostal space, and a little within a vertical line passing through the nipple. The effect of enlargement is to lower the apex and carry it to the left. It may be lowered to the sixth, seventh, eighth, or even as low as the tenth intercostal space, and, at the same time, carried more or less to the left. You will please to bear in mind what was said with reference to overlooking the apex-beat, and considering an impulse above as denoting its situation. For, when there is considerable cardiac enlargement, we may have an impulse in all the intercostal spaces between the base and apex. Removal of the apex-beat slightly to the left may be due to hydroperitoneum, gastric tympanites, pregnancy, etc., but none of these causes produce *lowering* of the apex-beat. The lowering of the apex-beat and its removal to the left are very good criteria for determining the fact and degree of cardiac enlargement.

Another mode of determining the degree of enlargement is by finding how much the area of the superficial cardiac space is increased; and that is ascertained by percussion. In certain cases in which the chest is thickly covered with adipose, or the mammary gland is excessively developed, percussion is not as valuable a means for this purpose as auscultation of the voice. For instance, you will place the stethoscope upon the upper part of the chest and get the vocal resonance; then move the instrument downward, getting the vocal resonance each time it is moved, until you find it abruptly ceasing or greatly diminished, when you may be sure that you have reached the border of the lung.

We have then, in proportion to the amount of enlargement, the superficial cardiac space increased in area, as shown by percussion and auscultation of the voice; and, as far as percussion goes, there is increased degree of dullness as compared with health.

By what means are we to determine, in cases of enlargement of the heart, whether the hypertrophy or the dilatation predominates? Reference has already been made to this question, but it is not improper to gain allude to the means employed, because of the important bearing which the answer to the question

has upon prognosis and treatment. We determine first by palpation: that is, by the strength of the impulse given to the hand as it is placed over the precordium. In some cases, in which the hypertrophy of the ventricular wall is the leading element, the ventricular contraction is so strong that the heart can almost be held in the hand at each cardiac pulsation. We can judge of the strength of the muscular contraction of the organ by the sense of touch.

Another mode is to direct your attention to the strength of the first sound of the heart. For, in proportion as the heart is enlarged by hypertrophy, is the first sound prolonged and louder, and the booming quality is more marked than in health. In proportion as dilatation predominates, the muscular walls of the organ are weakened and the first sound is feeble; not infrequently weaker than the second sound, and at the same time is shorter. The booming quality is lost, and in place we have the same quality that belongs to the second sound; that is, it is valvular in character. There are other points which might be mentioned in this connection, but these may be sufficient for practical purposes if they are well employed.

## TREATMENT OF VALVULAR LESIONS.

I will now ask your attention to the treatment of valvular lesions, with and without enlargement of the heart. We frequently find in practice evidence of valvular lesions either without, or with only very slight cardiac enlargement. What are the indications for treatment in cases in which valvular lesions are present, but have not led to enlargement of the heart, or at most only very slightly, and that in the way of hypertrophy? *There are no special indications*, and that is an important statement. It is not infrequently the case, when valvular lesions of the heart are discovered, that the practitioner feels it to be a very serious matter, and that it must be met correspondingly with injunctions regarding habits of life, and perhaps with regard to the use of remedies. There are certainly no indications for the use of remedies with the view of removing the lesions. These must be accepted as they are; and yet I have known patients to be placed under treatment in consequence of the vague and irrational idea that remedies might have something to do with diminishing the valvular lesion. But are we to ignore the lesions altogether? Not altogether; we are to take into consideration the possibility and the probability that they will increase. Although there are no symptoms, at present, indicating the existence of the trouble, and the lesion would not have been known, save by physical signs, the probabilities of increase of the lesion must be taken into consideration, and an endeavor made to forestall such increase; to render it as slow as possible. How shall this be done? We make the endeavor by giving certain directions which relate to the general regimen of the patient. In some instances, but this must needs be done with great discretion, it may be well to state to the patient that he has valvular lesion of the heart, as it may make him more considerate with reference to proper care for himself.

It is proper to advise this class of patients not to overtax the heart more than cannot be avoided, either by improper muscular exercise or great mental excitement. We should not go too far in our injunctions, as is too frequently done. It is not uncommon for physicians to overestimate the danger as regards the progress of the lesion, and to place restrictions upon the patient which are unnecessary, and which, perhaps, expose him to very great inconvenience. I

will give you the rule which I have adopted in giving these patients general directions.

With regard to exercise and excitement, it is not only proper, but advisable to say that such amount of physical exertion should be made as can be done with entire comfort. The patient will receive no harm from muscular exercise, if it simply be limited by the sense of comfort. Muscular exercise which does not excite the action of the heart so as to occasion discomfort is to be indulged in, for it can be done with benefit. The same rule holds good with regard to mental excitement. All mental excitement, if possible, should be avoided which increases the action of the heart to such an extent as to give rise to a sense of discomfort.

As a general statement, the amount of enlargement of the heart, and the kind of enlargement, are to be considered as criteria of the importance of valvular lesions. But before enlargement has taken place, it is an interesting point of investigation to form some idea regarding the amount of valvular lesion. The murmurs give us no definite indication, for the intensity of the murmur has no relation to the amount of lesion. We may have an intense murmur with a very small lesion, and, on the other hand, we may have a feeble murmur with a very extensive lesion. Is there any means by which we can obtain information concerning the degree of the valvular lesion, before the heart has become much enlarged?

We may obtain information by directing attention to the second sound of the heart as heard in the second intercostal space upon the left and right side of the sternum. Upon the right side of the sternum, in the second intercostal space, is the point where the aortic second sound is heard. The second sound heard in the second intercostal space on the left side of the sternum is produced mainly by the pulmonic valves.

The information regarding the degree of valvular lesion present is obtained by comparing the aortic second sound with the pulmonic second. First let us suppose we have evidence of valvular lesion at the aortic orifice, as shown by the presence of a direct or regurgitant murmur, or both. We wish to form an opinion as to whether much damage, if any, has been done to the aortic valves. We then compare the aortic second sound with the pulmonic second sound, and if it is found to stand in its normal relation with the pulmonic second sound, we may be sure that the amount of damage done to the aortic valves is not very great. In health the aortic second sound is somewhat louder, higher in pitch, and has more of the valvular quality, the short, clicking character, than does the pulmonic second sound. In proportion as the function of the valves is impaired by lesions, will the intensity of the sound be diminished, and if the aortic valves have undergone great damage the aortic second sound may be entirely wanting. We have then a ready way of determining to what extent damage has been done at the aortic valves.

Suppose we have mitral lesion, either obstructive or regurgitant, or both. We may form a judgment regarding the amount of regurgitation or obstruction by comparing the aortic second sound with the pulmonic second sound. In proportion as we have contraction of the mitral orifice, the left ventricle contracts upon an insufficient quantity of blood to fully dilate the aorta and its branches, the recoil of the arteries is less, the valves are expanded with less force, and there is a proportionate weakening of the aortic second sound as compared with the pulmonic. The effect, then, of mitral obstructive lesion is to weaken

the aortic second sound. If the mitral obstructive lesion has led to enlargement of the heart, we have seen that the right ventricle is the part especially hypertrophied, and the hypertrophy of the right ventricle is represented by the intensity of the pulmonic second sound. There is, then, with mitral direct lesion, involving contraction at the mitral orifice, an abnormal relation between the aortic second sound and the pulmonic second sound, consisting in a weakening of the aortic and an intensifying of the pulmonic when hypertrophy of the right ventricle has taken place.

The same is true of mitral regurgitation. A less quantity of blood is sent to the aorta, the recoil of the artery is diminished, the valves are expanded, with less force than normal, and, as a consequence, the aortic second sound is weakened; and when the right ventricle becomes hypertrophied, the pulmonic second sound becomes intensified.

This is of practical utility in forming a judgment with regard to the extent of the valvular lesions.

We have seen that the first effect produced by valvular lesions of the heart is to produce hypertrophy, and such hypertrophy is conservative; it has a real value and advantage. If it were practical to diminish the hypertrophied condition, the patient would be placed in a very much worse condition by so doing.

As a general statement, patients with valvular lesion of the heart do not suffer much inconvenience as long as the hypertrophy, which follows, predominates. A patient with hypertrophy of the heart predominating may take considerable muscular exercise with advantage, but he should carry it only to such an extent as he can do without suffering the least discomfort.

When, however, the dilatation predominates over the hypertrophy, the symptoms to which I called your attention in a previous lecture are developed—such as dyspnoea, first upon exertion, next when at rest, and general dropsy.

We will now assume that there is evidence of dilatation of the right ventricle; that the patient cannot take but little exercise without suffering from dyspnoea in an extreme degree, perhaps is unable to assume the recumbent posture, and there is cyanosis with more or less dropsy. What are the indications for treatment? The heart may be beating regularly or irregularly; different cases differing in this respect without apparent reason for such difference. It is proper, if possible, to remove the dropsy. We usually endeavor to do this by the judicious use of hydragogue and diuretic remedies. In this way we may be able, perhaps, to relieve the patient of his dropsy.

We may also relieve the dyspnoea by the judicious use of certain measures. Opiates may sometimes be resorted to, but very carefully. Some prescribe ethereal preparations, and these often afford marked relief.

We can hardly expect to relieve the patient of dyspnoea, especially upon exertion, as we may expect to succeed in removing the dropsy. However, these symptoms claim palliative measures of treatment.

Now, as regards the heart itself. We may often under these circumstances, derive great benefit from the use of digitalis, especially when the heart is irregular in its action. A feeble, irregular action of the heart is the condition which is most likely to be benefited by the judicious use of digitalis. It is unnecessary to carry it to very large doses; ten or fifteen drops of the tincture may be repeated at rather short intervals, the object being to keep up the *continous* effect of the drug. The effect frequently in this class of cases is to produce regularity of the heart.

tion, diminish the frequency of the heart-beat, and increase its power, thus accomplishing the objects desired. Now, while this is being done, the great object of treatment, other than the relief of special symptoms, is to improve the condition of the blood by improving the general condition of the patient. In other words, our object is to put the system in such condition as will best tolerate an affection which must continue and increase. These patients, not infrequently, are anæmic, and this condition of the blood always increases their distress and suffering; in short, all the symptoms incident to cardiac disease. We can restore the blood to its proper condition, perhaps the patient may tolerate the cardiac affection without much inconvenience. If anæmia is present, we endeavor to restore the blood to its proper condition, not only by the use of chalybeates, but by the use of such measures as will improve digestion, etc. The vital principle in the treatment of cardiac diseases is to endeavor to improve the general condition of the system, with the view of securing as much tolerance of the affection as possible.

#### TREATMENT OF AORTIC LESIONS.

I pass now to the treatment of aortic lesions, which presents some points of difference as contrasted with the treatment of other cardiac lesions.

We do not have dyspnoea, we do not have dropsy unless enlargement by dilatation has extended to the right side of the heart. Hypertrophy and dilatation of the left side of the heart, dependent upon aortic lesions, do not lead to dyspnoea or general dropsy. They involve distress which is described as palpitation or a sense of discomfort referable to the precordia. The suffering may be very great, but it is not, properly speaking, dyspnoea.

Now it has been stated that in cases of aortic lesions, especially involving free regurgitation, there is danger of sudden death, and that fact is to be considered in the treatment of this class of cases. Other things being equal, the danger of sudden death is in proportion to the regurgitation at the aortic orifice and weakening of the left ventricle by dilatation.

What can be done to relieve the distress of the patient and prevent a fatal termination?

We may have here, as with mitral lesions, a feeble, irregular action of the heart. Shall we employ digitalis, as in the treatment of the same condition in connection with mitral lesions? There is a difference of opinion with regard to the correct answer to this question. Some consider that this remedy may involve danger, and in this manner: if it has the effect of diminishing the frequency of the heart's action, overloading of the left ventricle is more likely to occur; hence the patient is exposed to more danger from paralysis of the heart, and thereby sudden death. On the other hand, it is argued that by giving greater force to the heart's action, notwithstanding the diminished frequency, the patient is less liable to have over-accumulation of blood in the left ventricle. As, as my experience goes, the truth lies between the two extremes, I would use digitalis with a certain amount of reserve in the treatment of aortic lesions. It seems to me evident that in certain cases benefit follows the judicious use of the remedy. We can give without running the risk of producing much slowing of the heart's action, and thus secure the tonic effect of the remedy without incurring the danger which deters some from employing it at all. As regards other measures to be employed, the same general principle is applicable as in the treatment of other cases. The general condition of the patient is to be

improved as much as possible, especially with reference to anæmia. It has been justly said that "a lame heart needs good blood." Active muscular exercise or great mental excitement are to be especially avoided in aortic lesions in which there is evidence of free regurgitation at the aortic orifice, and evidence of dilatation of the left ventricle. Under those circumstances we should not hesitate to caution the patient, and perhaps it may not be imprudent in certain cases to intimidate the patient by telling him there is danger of sudden death unless certain prudential measures are observed.

## Original Communications.

### THE PREVENTIVE TREATMENT OF CERTAIN DISEASES—A NEW METHOD OF PROPHYLACTIC PRACTICE.

By EZRA M. HUNT, M.D.

METUCHEN, N. J.

THE power which, through disinfectants or by other methods, we may exercise in preventing or limiting morbid action, is one of the studies which has the right to attract the most astute attention of the physician, the surgeon, and the sanitarian.

There are two facts thus far prominently before the profession, and accepted by a sufficient number of careful practitioners to entitle them to the closest investigation from us all.

I. The one is, that by the use of disinfectants, and especially by the use of the spray and of instruments which have been disinfected, we may prevent inflammation, and so render defensible and successful manifold operations which otherwise are of doubtful expediency. If openings into joints and various other exposures of surfaces are chiefly hazardous by reason of their exposure to the causes of inflammation and suppuration, and if these causes are set aside by the methods of carbolic exclusion, then a fact of no small import is in possession. Whatever may be the variety of opinion, it cannot but be recognized that disinfection of wounds in some form commends itself to the experience of very many surgeons. A large number, indeed, are accepting the higher faith of Lister as to the relations of germ-productivity to inflammation. Whether the result is secured by the exclusion of air, by cleanliness, by an action of presence, by a destruction of germs, or by some incompatibility of the disinfectant with the abnormal changes sought to be initiated, is a distinct subject of inquiry. But if the resultant fact of the prevention or arrest of morbid action is authenticated, it is a life and limb-saving discovery foremost in the present era of surgery.

II. The second fact prominently before us is that filth has such a relation to a class of diseases as really to characterize them as "filth diseases," and that the disinfection of the surroundings and voided secretions of these diseases is the important method of preventing their spread. This may perhaps be designated as the Simon view. The investigations of Dr. John Snow in cholera, and of Sir William Jenner in enteric fever, threw much light in this direction; but Simon and other pathologists would extend the observation "to every disease, whether nominally common or specific, in which the human intestinal canal is the seat of infected changes." They would include also such diseases as scarlatina, diphtheria, erysipelas, etc., which, for the want of a better term, are called zymotic. Water-pollution, air-pollution, ground-pollution, and

excremental pollution are regarded as the artificial fertilizers. It is claimed that disinfectants can so destroy the productivity of these disease-factors of filth as to tame or prevent disease.

Here again there are collateral questions intensely interesting, but not to be confounded with the question of result sought to be established. Whether each disease has its special fertilizer, whether definite combinations of filth can by chemical action or germ-productivity, either animal or vegetable, originate disease or give specificity thereto, these and other points pressingly invite investigation.

But if "common filth" incubates a whole class of diseases, or adds to their malignancy, and certain methods of outside management can so modify or abate this power as to annul or suspend it as a cause or promotive, we will at once apply it, although we cannot settle just now these other points.

Here again, facts as to limitation and prevention by the use of disinfectants have so far accumulated and have so far commended themselves to large numbers of practitioners as to lead us to feel that the antiseptic treatment of the surroundings of manifold diseases is a preventive and curative agency of the very weightiest concern in the practice of medicine. Those who come to realize to the full extent the best methods of preventing, limiting, or controlling disease by external appliances to surroundings, and who show by results what is actually accomplished, magnify the science and art of medicine to a degree that makes an era in its practice equal to this traumatic triumph in surgery.

III. We would add a third department of investigation akin to these, and equally worthy of the most enthusiastic and exact research. Can we not, by means of antiseptics or other medicaments, so deal with the human system itself as to render it either invulnerable or unslayable by some of the contagia? Are there not certain articles that can be introduced into the system which will negative the capacity of such a disease as scarlatina to incubate therein, or so accompany it with a modified condition of the fluids as to restrict its capacity for harm-doing and make the malign benign? May we not suspend or prevent the morbid action of the toxic by an infusion into the body of substances which will resist the zymotic or other action which is necessary to constitute the morbid success of the disease, and so interrupt its fructification and proliferation as to make it miscary?

A person may have already contracted the small-pox, and yet the *after-vaccination*, if not too long delayed, interferes with the course of the infection, and in part aborts it. In other cases there is reason to believe that it entirely prevents, or, in other words, supersedes and suspends, although the small-pox contagion had the advantage of preoccupation. After a number of trials, it is my confidence that when a case of scarlet fever occurs in a family of children, all those who would be liable to take the disease from this case may be prevented from so doing, or have the severity of the attack greatly modified, if immediately placed upon prophylactic treatment.

The following most recent case will illustrate: E. M., aged seven years, was taken sick, and after one day of vomiting and high fever, had a bounteous eruption, and became seriously sick with scarlatina anginosa. His brother, a child of two years, had been fully exposed until the second day. He is a child weighing forty-four pounds, and so about fifteen pounds over the average weight of children of his age, and a bad subject for the disease. I at once placed him on a solution of chlorate of potassium,

two to three grains in water three times per day, to which each time four drops of Squibb's Tinc. Chlorid. Ferri was added. He was allowed regular diet, except fats and sugar, which were prohibited. It was directed that he have each day a bath strongly impregnated with carbolic acid.

He has escaped the disease. My trials have been confined chiefly to scarlet fever and diphtheria. When the case is not seen soon after the first exposure, the doses must be larger and oftener, and quinine in addition is indicated to forestall diphtheria. By a system of medication, by care as to diet and ablation, by the use of disinfectants to some extent in the room, and by exclusion after the case was fully determined, I have been so often successful in families of children and in private schools, in limiting the disease, that the fact has become recognized in my practice. I have not always been able to assure myself how far the result depended on one or on all these methods combined. Yet so often has real exposure occurred, I have come to attach more importance to the internal administration of certain preventives than to any other method, and to entertain the hope that a large number of diseases thus admit of limitation.

We keep in the air-entrances and the blood the presence of certain substances which we believe interfere with those fermentive or other changes essential to the incubation and permeation of many diseases. If only the effect can be produced soon enough, and prolonged during the prodromal period, the action of the disease toxic is suspended. While we think the remedies we have named most potent, yet salicylic acid, quinine, phenol, and most disinfectants have some agency. They must be so given as to be kept present in the breath and the system.

After what we know of inoculation and vaccination as modifying disease—of the power of age, of acclimation, and of the degree to which iron, chlorate of potassium, and various other articles resist the course of certain diseases, it is not a very wild excursion or hypothesis to suspect that by substances kept in the system for a time, we may temporarily establish similar deliverances from attack. If we can thus placiate contagion in duration, we make a grand stride in limiting and abating disease. We ask the attention of such members of the profession as will observe and record, and experiment accurately, to this investigation. When any one of the zymotic diseases occur in one member of a family of children, let the others, if they have been exposed, be placed on the preventive treatment, so that we may know how many who have been under treatment a week avoid the disease, and how many have it lightly. When, after the first case has recovered, there is possibility of infection from the house itself, the prophylactic treatment in diminished doses should be continued two or three weeks. If only we can direct attention more to the preparation of the individual for a disease, or if we can infiltrate the fluids or tissue with some antiseptic, catalytic or incompatible, as that the flying contagion find unfavorable conditions for settlement, and makes no demonstration, a great progress is made in the science and art of medicine.

The fact that we know that in certain diseases the body has been made, in a very short time, unresponsive and uncongenial, so that the disease has either not located, or, if located, has disappeared, is enough to excite the greatest hope that there is a way of dealing with the body exposed to contagious disease, in which it may be rendered uninhabitable for contagion, or it find such uncongenial preoccupation as to have no chance for active virulence and viciousness.

Are there not opposing forces to disease in its initiative as well as in its declarative stages? Can we not so surcharge or pre-empt the individual as to nullify the toxic of disease, or so dilute or suspend it as to make it harmless?

We place this directly alongside of the antiseptic treatment of surgery and the treatment of outside conditions of filth, and believe both thought and experiment point us to prodromal mastery over disease by an exact method of individual sanitation. If so, a discovery is made fraught with a great future. If not, attention is drawn to the preparation of the individual for disease in a way which may not be unprofitable.

## A MODIFICATION OF THE SIMS SPECULUM.

By BLENCOWE E. FRYER, M.D.,

SURGEON U. S. ARMY.

THOSE of the profession who most frequently have to make vaginal and rectal examinations, and to perform surgical operations in these passages, have long since decided, we believe, that the Sims speculum, of all the numerous instruments, is the one which is most generally applicable for the purpose—the simplest and best. This is probably true, at any rate, as far as regards the conclusions of specialists in the matter. In rectal examinations there can scarcely be a question, by any one who has used the Sims after trying other forms of rectal specula, but that the former allows the most complete view of the parts, and the best facilities for operation; yet, in the rectal cases more especially though it applies to the vaginal also, we have thought it would be still more advantageous if we could obtain at a glance a view of all the surface of the mucous membrane, and this is impossible with the solid instrument of Sims. In order, therefore, to gain the advantage we have mentioned, it occurred to

either way. In vaginal cases the same may be said; there too the *complete view at once* of all the mucous membrane, though rarely so often needed, is nevertheless at times required, and it is the more difficult as compared with rectal examinations—for in the former the pressure of the instrument is of necessity to be made more posteriorly, and gliding it far enough either way to obtain the view of the posterior portions is done at the expense of the retraction posteriorly, and of course with a diminution of the calibre of the passage—entrance of the canal, the loss following arising from the diminished amount of atmospheric pressure allowed to bear, which pressure, as is well known, is the essential factor in dilating the canals referred to, when a sufficient retraction posteriorly is had.

It may be objected, and reasonably, that with our modification there is a loss of light had in its use, from having less of the reflecting surface in the instrument; but we have not found this difference very material, and when on cloudy days we have had to make examinations, a reflector, such as is used as a frontal mirror in throat cases, has removed any difficulty from want of light.

It may be well to add for those who have never used the Sims speculum (and we know there are many who have not), or for those who have tried it and have been dissatisfied with it, that the proper position of the patient must be had, or the Sims instrument and its modifications are useless; with the patient in the correct position there can be no trouble. A very clear description of this position, with a good woodcut illustrating it, will be found in Prof. T. G. Thomas's admirable work on the Diseases of Women.

It is not of course our idea to suggest the wire instrument as a substitute for the solid speculum of Sims, but only as an addition to it, and mainly for such vaginal and rectal cases (in the latter it is obvious that it will be most frequently required) where a complete view of the whole lining membrane, and more especially of the posterior portions, is desired to be had at once.

FORT LEAVENWORTH, KANSAS,  
August 31, 1877.

that a speculum of the Sims pattern, constructed of four or more wires (the one we use is of four wires), each wire one-eighth of an inch in diameter, silver or nickel-plated, preserving in every respect the outline of the Sims speculum, would be all that is needed, and we some time since had Messrs. Tiemann & Co. make for us a speculum of wire such as we have described, and which we find exceedingly convenient. The accompanying woodcut shows very well the construction of the instrument; no explanation is necessary.

With this instrument a complete view of all the parts can be obtained *at once*, while to get such a view with the solid speculum of Sims it is necessary (from the fact that the portion of the mucous membrane covered by the instrument is of course hidden from the eye) to glide it one-half at least of its width

## Reports of Hospitals.

### BELLEVUE HOSPITAL.

#### NOTES OF PRACTICE AND PECULIARITIES OF TREATMENT.

#### DIFFICULT DIAGNOSIS—PROBABLE PHTHISIS—ABSENCE OF PHYSICAL SIGNS—DATA UPON WHICH THE PROBABLE DIAGNOSIS WAS MADE.

THE patient's present illness, he said, had been of only about four weeks' duration. He had not been quite well during the last four years, the chief complaint being a "running sore" upon the ankle. About two months ago he began to have a slight cough, but did not feel sufficiently sick to remain in the house. During the last four weeks he had been getting worse, and noticed that there was a sore spot upon the left side, in the axillary region. At first it appeared like a small boil. At the end of a week or ten days the little elevation broke, discharged a small quantity, but had remained quite sore, and at the time of the examination there was considerable induration of the tissues surrounding the point where the sore first commenced. It did not feel like an enlarged gland, but

was apparently a mass of indurated tissue freely movable beneath the skin. He coughed considerable during the night-time, expectorated quite freely, and for about two weeks had raised considerable blood. His skin was hot at night, and the fever was followed by sweating. His temperature (noon) was  $101\frac{1}{2}$  F.; the skin was moist, and the pulse 100 and pretty full. His appetite was moderately good. If we were to judge from the morning temperature, there was no time during the twenty-four hours at which he was free from fever.

*Physical examination of the Chest.*—The peculiar percussion note heard upon the anterior portion of the man's chest was well worthy of special attention. It sounded as though there was very marked dulness upon the left side; it sounded a trifle dull upon the right side; upon the left side it was really very dull indeed, but it was *entirely artificial*; that is, it did not depend upon changes affecting the lung-tissue underneath. For, upon auscultation, the vesicular respiration over the region of this dulness was perfectly good, and although there was dulness there, it was the natural resonance in that particular person's chest. Posteriorly was found fair resonance upon percussion over the right side of the chest, but upon the left side there was present a noticeable degree of dulness at the lower portion, and beneath it were heard a few subcrepitant râles. Upon the right side the breath sounds were apparently healthy.

Neither the history nor the physical examination in this case were satisfactory. The history was of only two or three weeks' duration, began with a slight cough; there had been spitting of blood once, and there had been a form of hectic fever. If the man had not spit blood, it was thought that the idea of his having phthisis could almost be dismissed. The amount of blood was probably not large, although he said he had raised considerable; and yet the visiting physician believed that when even so slight a hemoptysis as recorded was followed by such a febrile movement, there was reason to acknowledge the possibility that the patient had phthisis, although there were present no physical signs whatever. In this case, although the physical signs of phthisis were not well marked, there were subcrepitant râles at the lower portion of the left lung, and a noticeable degree of dulness upon percussion. It was believed that the probabilities were in favor of the presence of some tubercular lesion of the left lung, but how extensive it was difficult to say. In addition, he had the inflamed patch of subcutaneous connective tissue under the left arm. Just how that began could not be told from the appearance of the sore. It might have commenced as an inflamed gland which went on to suppuration and discharge, and there were left the results of the sloughing process. But it was not usual for inflamed glands to be surrounded by such a zone of inflamed connective tissue, and it was also difficult to tell how much of the fever belonged to the suppuration of the subcutaneous connective tissue which was still going on. It was thought that the man probably had phthisis, but positive diagnosis was not made.

Now as to treatment. Although the diagnosis was not certain, yet the condition of the patient was quite positive, and the principal symptom was the febrile movement. It was a febrile movement having an ascertained character. It was more marked in the afternoon than in the morning, and was attended by sweating. The indication was, evidently, to endeavor to break this fever up, and for that purpose it was thought to be the simplest method to place the patient upon the use of aromatic sulphuric acid and

the sulphate of quinine. He was, therefore, to receive

R Acid sulph. aromat. . . . . gtt. xx.

Quin. sulph. . . . . grs. v.

every three hours. The remedies were to be continued for several days with the hope that the temperature would fall under their influence.

VALVULAR LESION OF THE HEART—PROGNOSIS AFFECTED BY THE FACT THAT IT WAS NOT OF RHEUMATIC ORIGIN.

A boy, *æt.* 12 years, complained of what he called a "sticking in the two sides" after exercise. He said it was first noticed some three or four years ago, when he had been running after a wagon, and that he had had more or less of pain in the side, with *shortness of breath*, ever since that time. These symptoms had given him so much discomfort, and excited the anxiety of his parents to such an extent, that he had been taken to see a doctor, who told him he had heart-disease. He had never had rheumatism, nor had he had scarlet fever. Such was the history of the case; and then, as the chest was exposed, it was found that the cardiac impulse was quite forcible, that the area of cardiac dulness was somewhat enlarged, and that there was also a sort of thrill communicated to the fingers by the apex-beat. The heart-beat was regular. There was a very loud murmur with the first sound of the heart, heard with greatest intensity at the apex, but heard distinctly around the chest and behind. This murmur was evidence of regurgitation at the mitral orifice. There was also a loud murmur at the base, heard with the systole and transmitted into the subclavian arteries upon both sides. The boy then was suffering from organic disease of the heart, consisting probably in regurgitation at the mitral valve combined with some degree of lesion at the aortic orifice. These lesions had not produced any marked change in the cavities of the heart—that is, the ventricles were not dilated; but if any change had occurred, it was in the way of slight hypertrophy of the left ventricle. There were no symptoms of general venous congestion; there had never been any dropsy; there had been no cough, no hemoptysis, no vomiting, and no trouble from attacks of pain. He was well nourished and his appetite was very good. The only way in which his heart troubled him was by giving rise to shortness of breath upon exertion. With reference to *prognosis* in such a case as this, it was regarded as very good for a case of cardiac disease. A great many children having such an amount of heart-disease, and *without rheumatism*, as this boy had, grow up and enjoy very good health. They carry the heart-disease, the valves work imperfectly, and yet the general circulation does not become so disturbed as to prevent good health; they simply have the liability to shortness of breath upon exertion. The prognosis with heart-disease in children, it was claimed, varied according as it depended upon articular rheumatism. When a child had had one attack of rheumatism it was liable to have others, and, if the heart became affected during the first attack, as it was very likely to be, every succeeding attack rendered the cardiac disease worse. But when heart-disease occurred uncomplicated, or independent of rheumatism, the prognosis was believed to be much more favorable.

As regarded treatment, there was really no special indication in the case except to regulate the boy's method of living, regulate his diet, and also the various functions of the body. Keeping him from school had been a wise precaution. It would be beneficial could he be sent to the country during the summer

where his general health would probably be so improved that he could enter school again in the fall and continue through the winter. If his appetite became poor, it must be restored by the use of appropriate remedies, perhaps iron and quinine, and iron would be indicated if he became anæmic. If he lost flesh, he should take cod-liver oil. As he now stood, at the time of the examination, he was in a very good condition, and the chief object was to maintain his nutrition.

VALVULAR LESION OF THE HEART—PROGNOSIS SPECIALLY VARIED BY THE HABITS OF THE PATIENT.

A male patient, æt. 35 years, was not aware that he had any trouble until four or five weeks ago, when he "felt something different from usual upon the left side of the body." Upon closer examination it was found that the cause of complaint was a feeling of "pain and oppression," beginning in the precordia and passing up into the left shoulder and down into the left arm. The suffering caused in this way was sometimes so intense that he was obliged to get out of bed, and had recurred at intervals of two or three weeks. There was no sense of impending death. He did not suffer from shortness of breath, but had palpitation when he walked fast. He had not had rheumatism. He had suffered more from this sense of discomfort and pain since he had been told that he had heart-disease. On physical examination, it was found that the heart was considerably enlarged, that it had a pretty forcible impulse, and that there was a loud double murmur at the base. There was regurgitation at the aortic orifice, and some rigidity or some roughening of the aortic valves. With the trouble at the aortic orifice, he also has dilatation with hypertrophy of the left ventricle.

It seemed, then, that the only way in which this man's heart troubled him was in the production of a feeling of oppression and discomfort upon the left side of the chest and occasional attacks of severe pain, beginning over the upper part of the sternum and passing across to the left shoulder and then down the left arm; those attacks of pain, however, were not frequent. The most that troubled him was a consciousness that the left side of the chest did not feel perfectly well, and he had felt worse since he had become aware that he had heart-disease. It was believed that in such cases as this the physician is justified in not letting the patient know that he has heart-disease. It was also said that in such cases but little remained to be done in the way of *treatment*, for the man felt very well, except with reference to the sense of discomfort on the left side of the body. The only thing suggested was to be very careful regarding diet and drink. The heart itself was perhaps too much hypertrophied, and beat more forcible than was necessary to compensate for the deficiency in the valves. It was also believed to be probable that it was the excessive action of the heart that gave rise to the sense of discomfort in the left side of the body. But, in order to improve that condition of the heart, it was not thought necessary to give medicine, but it was deemed necessary to be guarded with reference to food and drink. All wines and spirits and tobacco were forbidden, and it was believed that such total abstinence would be followed by good results. There was no reason why he should not eat three fair meals each day, but they should be simply plain and nutritious. Meat, not much fat, bread, vegetables, and fruits were recommended; but milk, eggs, tea, and coffee were excluded.

It was thought that by such regulation of the man's diet he might enjoy pretty good health for a year or

more; but if he should conclude to go on two or three sprees, or walk a great deal, he would soon be in the hospital, and in an œdematous condition.

THE MEDICAL SIDE OF HEMORRHOIDS—PATHOLOGY—TREATMENT—GYMNASTICS AND MEDICINES—IRRITABILITY OF THE MUCOUS MEMBRANE OF THE BLADDER—DANGER OF ENLARGED PROSTATE—SPECIAL CATHARTICS—WARNING AGAINST THE USE OF SULPHUR, HYDRAGOGUES, AND RESINOUS CATHARTICS—WARNING AGAINST THE IMPROPER USE OF MINERAL WATERS OR SALINES.

It was maintained that hemorrhoids are caused, *simply and solely*, by a slow return of circulation from the abdominal viscera through the liver. Surgical means, therefore, in the treatment of this disease, were regarded as always merely palliative, because they did not deal with the true course of the affection.

The treatment, of course, has special reference to increasing the activity of the portal circulation.

In the first place, such exercise must be insisted upon as will strengthen the abdominal muscles. To that end there is a gymnastic movement which is specially adapted to bringing about such a result, and at the same time assists the action of certain remedies. It consists simply in trying to touch the toes with the fingers without bending the knees. This movement, although difficult at first, soon becomes easy, and develops not only the muscles of the abdomen, but also of the legs and thighs. As soon as possible, it should be repeated at least a hundred times every morning.

Next, stimulate the circulation through the abdominal viscera by cutaneous irritants. Sponge the abdomen with salt water and pepper—for example, a dram of red pepper, one ounce of salt, and one quart of water, and used cold.

Douching the spine in the morning is also very serviceable.

All these applications are especially adapted to the treatment of piles, prolapsus of the rectum, and constipation.

If, however, the piles are inflamed and bleeding, recourse should not be had to the gymnastic exercise until the acute attack has subsided, because the straining will be likely to increase the trouble. There is, however, but little danger of increasing the protrusion when inflammation is not present.

The faradic current is another adjuvant in the treatment of sluggish portal circulation, placing one pole over the spine and the other over the liver.

The hemorrhoidal veins, being farthest from the liver, suffer most on account of obstructed portal circulation, and they are acted upon by the abdominal muscles, which assist in emptying them.

When piles are severe, they are quite commonly attended by irritability of the bladder as well; and such irritability, manifesting itself by a burning sensation, which may continue for some time after micturition, is evidence of congestion of the mucous membrane, and also the plexus of veins about the prostate. It was believed that if such congestion was permitted to continue for a year, there was a fair chance that the patient would have permanent enlargement of the prostate gland; and also that those means which were best adapted to restoration of the proper activity of the portal circulation would give the greatest amount of relief to patients afflicted with such enlargement.

Now for the

MEDICINAL MEANS

by which the torpor of the portal circulation is to be removed.

The first and foremost of these is a cathartic; but it was maintained that there was *only one kind* which could be successfully used for that purpose.

The ordinary mild cathartics, such as castor oil, rhubarb, sulphur, etc., were objected to. Special warning was given against the use of sulphur, notwithstanding its popularity in the treatment of piles, because of the debility which follows its use, and the irritation of the piles which it produces. The hydragogues and the resinous cathartics, it was believed, were contraindicated, because anything which produces prolonged catharsis is injurious, for the reason it gives rise to congestion, perhaps inflammation of the mucous membrane of the lower part of the bowel. Fortunately, any large excess of the natural salts of the blood is gotten rid of almost entirely by the mucous membrane of the alimentary canal, and it can be removed through that channel without debilitating the patient to any considerable degree. There is less debility, it was said, following a diarrhœa caused by these salts than by any other cause. It is much less than the debility which follows diaphoresis or diuresis. The almost exact proportion of salts normally present in the serum of the blood is found in some of the mineral waters; hence their special adaptability as agents for producing catharsis without causing debility or disturbance of digestion.

In the treatment of piles, therefore, it was recommended that the patient should drink one or two pints of Congress or Geyser water every morning, so as to insure one free, watery evacuation from the bowels after breakfast.

Such means was regarded as the most efficient at our command for unloading the portal circulation. Continue such a course for six or eight weeks. At the end of that time the patient may have a severe attack of piles. If so, it is a very good sign, as probably it will be the last attack he will have. The salines can be stopped for a few days, and the piles will not only get well of the inflammation, but will shrink up and disappear. The visiting physician remarked that he had succeeded so often in curing chronic cases of bleeding, internal, and external piles by this plan of treatment, he had no hesitation in recommending it as the most available means at our command for giving permanent relief in this affection. Accompanying these remarks regarding the use of mineral waters,

#### THE WARNING WAS GIVEN

that salines should never be prescribed for any one whose weight had been diminished by reason of any morbid condition. The very nervous person, also, who usually has but little fat, does not sleep well, urine alkaline or only feebly acid, usually is made worse by a visit to Saratoga, if he drinks much of the water.

The class which is almost always benefited, and benefited when other means have failed, are those who have obstruction of the portal circulation as the seat of their trouble, which manifests itself in the way of constipation, hemorrhoids, perhaps prolapsus of the rectum, with a tendency to cystitis, and perhaps enlarged prostate. Varicose veins of the legs, and sciatica, are also very common remote effects of the same cause, and can be most readily relieved by measures addressed to its removal.

## Progress of Medical Science.

**CASE OF ASCITES CURED BY COPAIBA RESIN.**—On November 11, 1876, a furnace-man, aged 45, was admitted into the Liverpool Royal Infirmary. He gave a history of cirrhosis of the liver; was emaciated and slightly jaundiced. There was extreme ascites, and the urine was greatly diminished in quantity, but contained no albumen. After paracentesis the liver was found to be contracted and nodulated. Between November 11, 1876, and February 24, 1877, the patient was tapped five times. Digitalis, juniper, gin, acetate of potash, and iron were given, but the urine continued scanty, and the fluid continued to reaccumulate in the peritoneal cavity. Finally, 20 grains of the resin of copaiba, with a little rectified spirit and mucilage, were given every four hours. The urine under this treatment rapidly increased in quantity, until, on an average, 150 ounces were passed per diem. The peritoneal cavity was entirely free from fluid on April 16th, when the resin was stopped and tincture of iron ordered. The patient rapidly regained strength.—*The Lancet*, July 14th.

**THREE CASES OF THORACIC ANEURISM TREATED BY ELECTROLYSIS.**—One of these cases occurred in the service of M. Dujardin-Beaumetz, at the Hôpital Saint-Antoine, in Paris. The aneurism, which had been growing for two years, formed a prominence on the right side of the sternum, extending from the third to the fifth rib. The pulsations were expansive, forcible, and easily perceived by the naked eye. In the operation a battery of Gaiffe, containing 26 elements, was used. Three needles were introduced into the tumor, one in the third and two in the fourth intercostal space, and the current was passed through each of them in succession for ten minutes. The negative electrode was applied to the right side of the thorax. During the passage of the current the patient experienced little pain. Four hours after the operation the pulsations had diminished notably in force, and the patient felt greatly relieved. On the next day the pulsations were scarcely appreciable in the fourth intercostal space, where they had previously been very marked. On July 10th, when the article from which the above is taken was written, the improvement still persisted. It was then the intention of M. Dujardin-Beaumetz to repeat the operation at intervals of about a month, in the hope of obtaining complete coagulation of the tumor. As, however, the patient is affected with hypertrophy and dilatation of the heart and aortic insufficiency, it is not likely that the improvement will be sufficient to enable him to resume his former occupation.

The other two cases are reported by Dr. Henry Simpson, of the Manchester Royal Infirmary. In one of these cases the tumor first appeared in the second left interspace, close to the sternum, where pulsation was evident both to touch and sight. After several months, solidification of the upper portion of the aneurism took place, and it gradually changed its position, sinking lower down behind the sternum, and leaving its former site resonant on percussion. In January, 1876, ten months after the first symptoms of the affection were noticed, there was a prominent, pulsating eminence occupying the lower portion of the chest, from the level of the nipple to the ensiform cartilage, and at one point a distinct sense of fluctuation was felt over a space as large as a shilling. Electro-puncture was used on three occasions, and on

**MORTUARY RECORDS.**—St. Louis has an ordinance for the proper keeping of mortuary records.

one occasion the current from thirty-five cells was passed through the tumor for three hours, by means of wet sponges. Foveaux's battery was the one employed. In the two first operations of electro-puncture eight cells were used, and in the third thirty-five cells. The tumor felt somewhat firmer after the first operations, but there was no marked change in it. Hemorrhage took place several times from the punctures, and the patient died seven days after the last operation, from syncope after losing a few ounces of blood. At the autopsy the aneurism was found to be altogether within the pericardium.
